<b>Address Offset</b>	0x0000 0038	<b>Instance</b>	EMIF
<b>Physical Address</b>	See <a href="#">Table 15-126</a>		
<b>Description</b>	Power Management Control Register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																REG_PD_TIM				REG_DPD_EN	REG_LP_MODE	REG_SR_TIM				REG_CS_TIM					

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:12	REG_PD_TIM	Power Mangement timer for Power-Down. The EMIF will put the external SDRAM in Power-Down mode after the EMIF is idle for these number of DDR clock cycles and if reg_lp_mode field is set to 4. Set to 0 to immediately enter Power-Down mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks.	RW	0x0
11	REG_DPD_EN	Deep Power Down enable. Set to 0 for normal operation. Set to 1 to enter deep power-down mode. This mode will override the reg_lp_mode field setting.	RW	0
10:8	REG_LP_MODE	Automatic Power Management enable. Set to 1 for Clock Stop, set to 2 for Self Refresh, and set to 4 for Power-Down. All other values will disable automatic power management.	RW	0x0
7:4	REG_SR_TIM	Power Mangement timer for Self Refresh. The EMIF will put the external SDRAM in Self Refresh mode after the EMIF is idle for these number of DDR clock cycles and if reg_lp_mode field is set to 2. Set to 0 to immediately enter Self Refresh mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks.	RW	0x0
3:0	REG_CS_TIM	Power Mangement timer for Clock Stop. The EMIF will put the external SDRAM in Clock Stop mode after the EMIF is idle for these number of DDR clock cycles and if reg_lp_mode field is set to 1. Set to 0 to immediately enter Clock Stop mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks.	RW	0x0

**Table 15-175. Performance Counter Filter Configuration**

CNTRn_CFG	CNTRn_REGION_EN	CNTRn_MCONNID_EN	Description
0x0	0x0	0x0 or 0x1	Count total SDRAM accesses
0x1	0x0	0x0 or 0x1	Count total SDRAM activates
0x2	0x0 or 0x1	0x0 or 0x1	Count total reads
0x3	0x0 or 0x1	0x0 or 0x1	Count total writes
0x4	0x0	0x0	Count number of DDR clock cycles L3 Command FIFO is full
0x5	0x0	0x0	Count number of DDR clock cycles L3 Write Data FIFO is full
0x6	0x0	0x0	Count number of DDR clock cycles L3 Read Data FIFO is full
0x7	0x0	0x0	Count number of DDR clock cycles L3 Return Command FIFO is full

**Table 15-175. Performance Counter Filter Configuration (continued)**

CNTRn_CFG	CNTRn_REGION_EN	CNTRn_MCONNID_EN	Description
0x8	0x0 or 0x1	0x0 or 0x1	Count number of priority elevations
0x9	0x0	0x0	Count number of DDR clock cycles that a command was pending
0xA	0x0	0x0	Count number of DDR clock cycles for which the memory data bus was transferring data.
0xB - 0xF	0x0	0x0	Reserved for future use.

**NOTE:** When MReqDebug is set to a 1 for a particular L3 command, the performance counters will not be incremented for that particular command if the CNTRn\_CFG values are equal 0x0, 0x1, 0x2, 0x3, or 0xA.

Table 15-175 shows the possible filter configurations for the two performance counters. These filter configurations can be used in conjunction with a L3 master ID and/or an external chip select to obtain performance statistics for a particular L3 master and/or an external chip select.

## 15.4 General-Purpose Memory Controller

### 15.4.1 GPMC Overview

The general-purpose memory controller (GPMC) is a unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (only available in non-muxed mode) burst NOR flash devices
- NAND Flash
- Pseudo-SRAM devices

### 15.4.2 GPMC Environment

This section describes the GPMC application fields from an environment point of view (external connections). It describes GPMC connectivity options, and gives three possible interfaces.

#### 15.4.2.1 GPMC Modes

This section shows three GPMC external connections options:

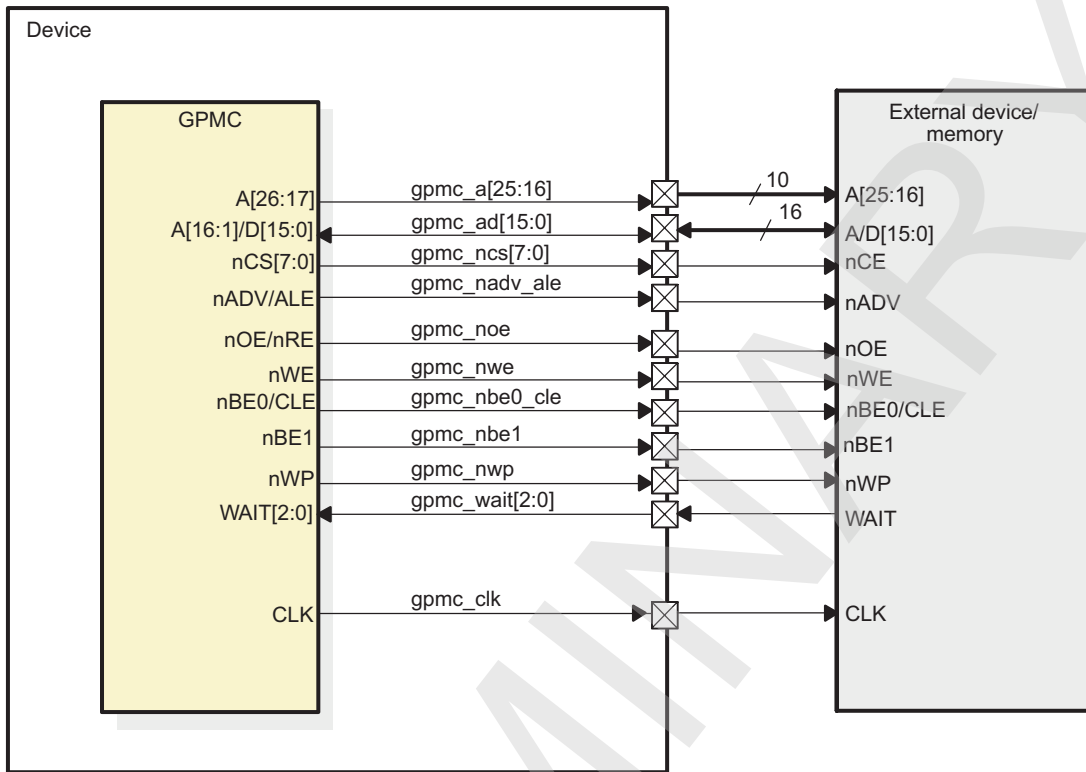

- [Figure 15-50](#) shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed, but this protocol use less address pins) external memory device ([Figure 15-50](#)).
- [Figure 15-50](#) shows a connection between the GPMC and a 16-bit synchronous nonmultiplexed external memory device ([Figure 15-51](#)).
- [Figure 15-52](#) shows a connection between the GPMC and a 16-bit NAND device ([Figure 15-52](#)).

---

**NOTE:** The device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for multiplexed and nonmultiplexed protocol). Hence, an 8-bit device must be connected to the D[7:0] / gpmc\_ad[7:0] data bus (rather than D[15:8] / gpmc\_ad[15:8]) of the GPMC controller. This limits the use of 8-bit wide device interfacing to byte-alias access.

### 15.4.2.2 GPMC Signals

Table 15-212 lists the GPMC subsystem I/O pins.

Table 15-212. GPMC I/O Description

Pin Name	I/O	Description
gpmc_a[25:16]	O	Address
gpmc_ad[15:0]	I/O	Data
gpmc_ncs[7:0]	O	Chip-selects (active low)
gpmc_clk	O	Clock generated for the external memory or device
gpmc_nadv_ale	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
gpmc_noe_nre	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
gpmc_nwe	O	Write enable (active low)
gpmc_nbe0_cle	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
gpmc_nbe1	O	Upper-byte enable (active low).
gpmc_nwp	O	Write protect (active low)
gpmc_wait[2:0]	I	External wait signal for NOR and NAND protocol memories. The wait signals can be mapped on any of the chip-select.
gpmc_io_dir	O	gpmc_ad[15:0] signal direction control: Low during transmit (for write access: data OUT from GPMC to memory), High during receive (for read access: data IN from memory to GPMC)

Table 15-213 shows the use of address and data GPMC controller pins based on the type of external device.

**Table 15-213. GPMC Pin Multiplexing Options**

GPMC Pin	Multiplexed Address Data 16-Bit Device	Nonmultiplexed Address Data 16-Bit Device With LIMITED- ADDRESS Bit Enabled	16-Bit NAND Device	8-Bit NAND Device
gpmc_a[25]	A26	A10	Not used	Not used
gpmc_a[24]	A25	A9	Not used	Not used
gpmc_a[23]	A24	A8	Not used	Not used
gpmc_a[22]	A23	A7	Not used	Not used
gpmc_a[21]	A22	A6	Not used	Not used
gpmc_a[20]	A21	A5	Not used	Not used
gpmc_a[19]	A20	A4	Not used	Not used
gpmc_a[18]	A19	A3	Not used	Not used
gpmc_a[17]	A18	A2	Not used	Not used
gpmc_a[16]	A17	A1	Not used	Not used
gpmc_ad[15]	A16/D15	D15	D15	Not used
gpmc_ad[14]	A15/D14	D14	D14	Not used
gpmc_ad[13]	A14/D13	D13	D13	Not used
gpmc_ad[12]	A13/D12	D12	D12	Not used
gpmc_ad[11]	A12/D11	D11	D11	Not used
gpmc_ad[10]	A11/D10	D10	D10	Not used
gpmc_ad[9]	A10/D9	D9	D9	Not used
gpmc_ad[8]	A9/D8	D8	D8	Not used
gpmc_ad[7]	A8/D7	D7	D7	D7
gpmc_ad[6]	A7/D6	D6	D6	D6
gpmc_ad[5]	A6/D5	D5	D5	D5
gpmc_ad[4]	A5/D4	D4	D4	D4
gpmc_ad[3]	A4/D3	D3	D3	D3
gpmc_ad[2]	A3/D2	D2	D2	D2
gpmc_ad[1]	A2/D1	D1	D1	D1
gpmc_ad[0]	A1/D0	D0	D0	D0

When using non-multiplexed memories, it is recommended to enable [GPMC\\_CONFIG\[1\] LIMITEDADDRESS](#). This bit forces A[26:11] to 1 on the GPMC I/O side. Thus, only 2Kbytes of memory address space is accessible regardless of the memory size.

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x00.

Address mapping supports address/data-multiplexed 16-bit wide devices:

- The NOR flash memory controller still supports non-multiplexed address and data memory devices.
- Multiplexing mode can be selected through the [GPMC\\_CONFIG1\\_i\[9:8\] MUXADDDATA](#) bit field (i = 0 to 3).
- Asynchronous page mode is not supported for multiplexed address and data devices.

---

**NOTE:** The numbering for A (address) is starting from 1 instead of 0 such as D (data) because the A0 signal is handled within the GPMC but is not driven to any pad. The signal is only relevant to 8-bit accesses and this configuration is not recommended. If such a memory or device is connected, only every second word in the memory is accessible, that is, each 16-bit aligned 8-bit word is mapped but not the non-16-bit aligned ones. Any access to a non-aligned one will actually result in accessing the associated aligned one, at address A1 instead of address A.

---

### 15.4.3 GPMC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- No STANDBY hardware handshake
- No wake-up request
- One system direct memory access (sDMA) request
- One interrupt request to the Cortex-A9 MPU Interrupt Controller (MA\_IRQ) and to DSP subsystem (D\_IRQ)
- One clock for functional and interface domains

Figure 15-53 shows GPMC integration.

Figure 15-53. GPMC Integration

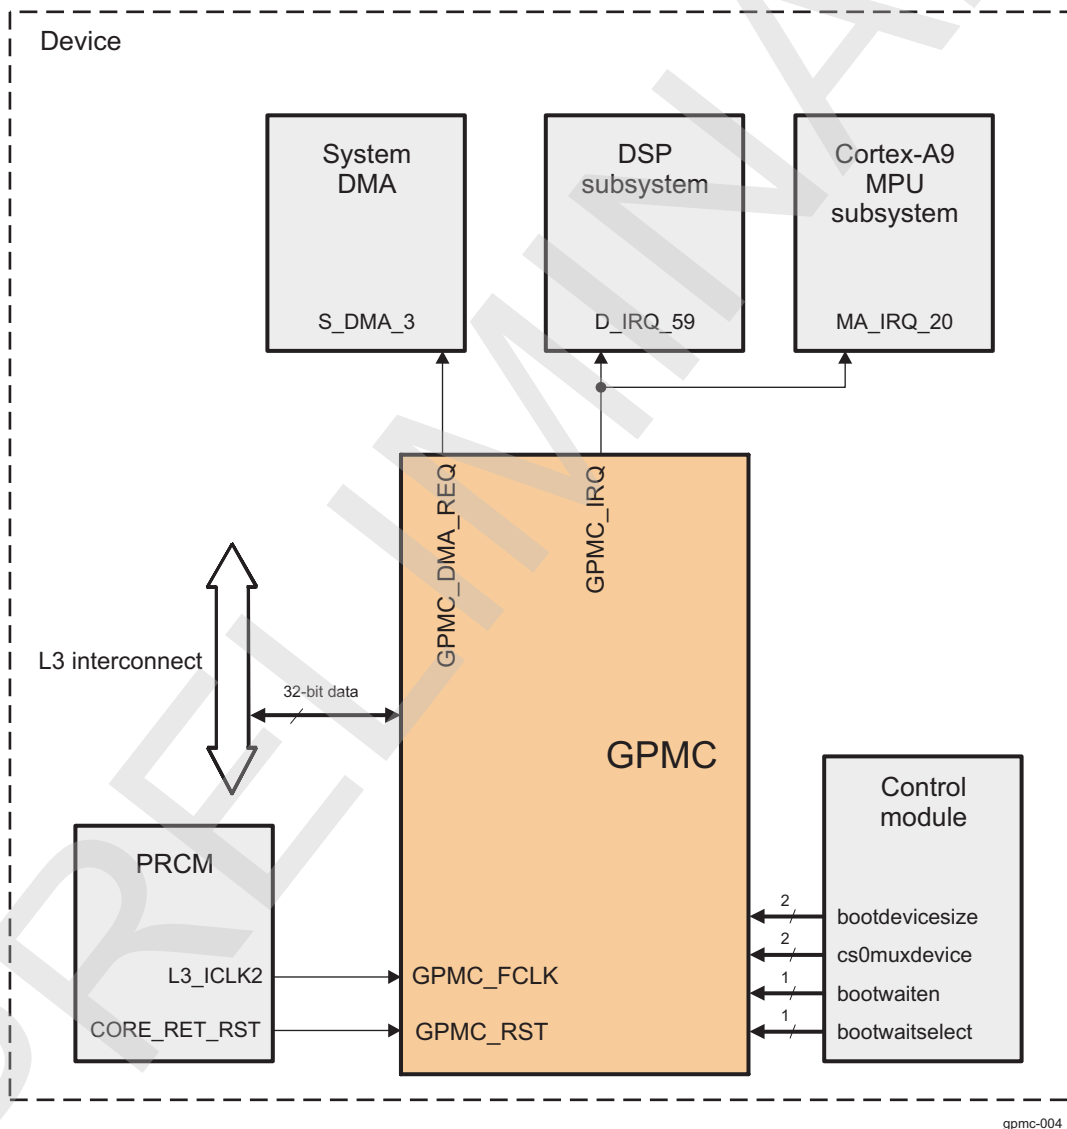

Table 15-214, Table 15-215 and Table 15-216 summarize the integration of the module in the device.

**Table 15-214. GPMC Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-up Capability	Interconnect
GPMC	PD_CORE	No	L3

**NOTE:**

- For information about operation performance point (OPP) configuration description, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

**Table 15-215. GPMC Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
GPMC	GPMC_FCLK	L3_ICLK2	PRCM	Functional clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
GPMC	GPMC_RST	CORE_RET_RST	PRCM	GPMC reset

**NOTE:** For clock description, see [Section 15.4.4.2, GPMC Clock Configuration](#).

**Table 15-216. GPMC Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
GPMC	GPMC_IRQ	D_IRQ_59	DSP	GPMC interrupt to DSP subsystem
	GPMC_IRQ	MA_IRQ_20	Cortex-A9	GPMC interrupt to Cortex-A9 MPU subsystem
DMA Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
GPMC	GPMC_DMA_REQ	S_DMA_3	sDMA	GPMC request from Prefetch Engine to sDMA

**NOTE:**

- For interrupt source description, see [Section 15.4.4.5, GPMC Interrupt Requests](#).
- For DMA source description, see [Section 15.4.4.6, GPMC DMA Requests](#).

### 15.4.4 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and the data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

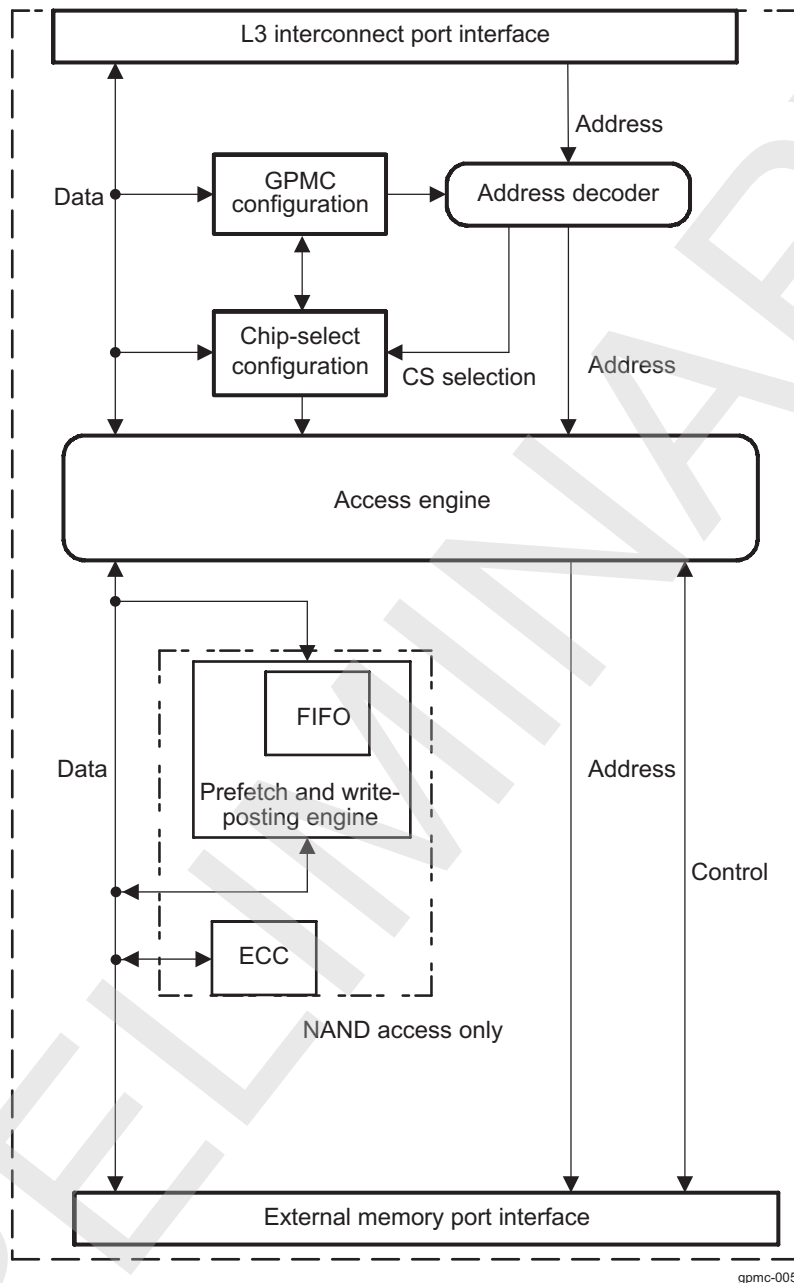

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC\_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

#### 15.4.4.1 GPMC Block Diagram

Figure 15-54 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- L3 interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

**Figure 15-54. GPMC Block Diagram**

The GPMC can access various external devices through the L3 Interconnect. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC is able to generate all control signals timing depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate device type control signals timing.

#### 15.4.4.2 GPMC Clock Configuration

Table 15-217 describes the GPMC clocks.

**Table 15-217. GPMC Clocks**

Signal	I/O <sup>(1)</sup>	Description
GPMC_FCLK	I	Functional and interface clock
gpmc_clk	O	External clock provided to synchronous external memory devices.

<sup>(1)</sup> I = Input; O = Output

The gpmc\_clk is generated by the GPMC from the internal GPMC\_FCLK clock. The source of the GPMC\_FCLK is described in [Table 15-215](#). The gpmc\_clk is configured via the [GPMC\\_CONFIG1\\_i\[1:0\]](#) GPMCFCLKDIVIDER field (for i = 0 to 3) as shown in [Table 15-218](#).

**Table 15-218. gpmc\_clk Configuration**

Source Clock	<a href="#">GPMC_CONFIG1_i[1:0]</a> GPMCFCLKDIVIDER	gpmc_clk Generated Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/4
	11	GPMC_FCLK/8

#### 15.4.4.3 GPMC Software Reset

The GPMC can be reset by software through the [GPMC\\_SYSCONFIG\[1\]](#) SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The [GPMC\\_SYSSTATUS\[0\]](#) RESETDONE bit indicates that the software reset is complete when its value is 1. The software must ensure that the software reset completes before doing GPMC operations.

#### 15.4.4.4 GPMC Power Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines.

[Table 15-219](#) describes power-management features available for the GPMC module.

**NOTE:**

- For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.6, Clock Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**Table 15-219. GPMC Local Power Management Features**

Feature	Registers	Description
Clock Auto Gating	<a href="#">GPMC_SYSCONFIG[0]</a> AUTOIDLE bit	This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity.
Slave Idle Modes	<a href="#">GPMC_SYSCONFIG[4:3]</a> SIDLEMODE bit field	Force-idle, No-idle and Smart-idle wakeup modes are available
Clock Activity	N/A	Feature not available
Master Standby Modes	N/A	Feature not available
Global Wake-up Enable	N/A	Feature not available
Wake-up Sources Enable	N/A	Feature not available

### 15.4.4.5 GPMC Interrupt Requests

The GPMC generates one interrupt event as shown in [Figure 15-53](#) :

- The interrupt request goes from GPMC (GPMC\_IRQ) to the Cortex-A9 MPU subsystem : MA\_IRQ\_20 and to the DSP subsystem : D\_IRQ\_59.

[Table 15-220](#) lists the event flags, and their mask, that can cause module interrupts.

**Table 15-220. GPMC Interrupt Events**

Event Flag	Event Mask	Sensitivity	Map to	Description
<a href="#">GPMC_IRQSTATUS</a> [10] WAIT2EDGE DETECTIONSTATUS	<a href="#">GPMC_IRQENABLE</a> [10] WAIT2EDGE DETECTIONENABLE	Edge	D_IRQ_59 and MA_IRQ_20	Wait2 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait2 signal. The rising or falling edge detection of Wait2 is selected through <a href="#">GPMC_CONFIG</a> [10] WAIT2PINPOLARITY
<a href="#">GPMC_IRQSTATUS</a> [9] WAIT1EDGE DETECTIONSTATUS	<a href="#">GPMC_IRQENABLE</a> [9] WAIT1EDGE DETECTIONENABLE	Edge	D_IRQ_59 and MA_IRQ_20	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait1 signal. The rising or falling edge detection of Wait1 is selected through <a href="#">GPMC_CONFIG</a> [9] WAIT1PINPOLARITY
<a href="#">GPMC_IRQSTATUS</a> [8] WAIT0EDGE DETECTIONSTATUS	<a href="#">GPMC_IRQENABLE</a> [8] WAIT0EDGE DETECTIONENABLE	Edge	D_IRQ_59 and MA_IRQ_20	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait0 signal. The rising or falling edge detection of Wait0 is selected through <a href="#">GPMC_CONFIG</a> [8] WAIT0PINPOLARITY
<a href="#">GPMC_IRQSTATUS</a> [1] TERMINAL COUNTSTATUS	<a href="#">GPMC_IRQENABLE</a> [1] TERMINAL COUNTENABLE	Level	D_IRQ_59 and MA_IRQ_20	Terminal count event: Triggered on prefetch process completion, that is when the number of currently remaining data to be requested reaches zero
<a href="#">GPMC_IRQSTATUS</a> [0] FIFOEVENTSTATUS	<a href="#">GPMC_IRQENABLE</a> [0] FIFOEVENTENABLE	Level	D_IRQ_59 and MA_IRQ_20	FIFO event interrupt: Indicates FIFO levels availability for in Write-Posting mode and prefetch mode. <a href="#">GPMC_PREFETCH_CONFIG1</a> [2] DMAMODE shall be set to 0.

### 15.4.4.6 GPMC DMA Requests

The GPMC generates one DMA event as shown in [Figure 15-53](#) :

- From GPMC (GPMC\_DMA\_REQ) to the system DMA (sDMA) : S\_DMA\_3.

### 15.4.4.7 L3 Interconnect Interface

The GPMC L3 interconnect interface is a pipelined interface including an 16 x 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-bit / 16-bit / 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 x 32, 4 x 32, 8 x 32 or 16 x 32 with the burst base address aligned on the total burst size are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line, for specific event control.

It is recommended to program the ATTACHEDDEVICEPAGELENGTH field ([GPMC\\_CONFIG1\\_i\[24:23\]](#)) according to the effective attached device page length and to enable WRAPBURST bit ([GPMC\\_CONFIG1\\_i\[31\]](#)) if the attached device supports wrapping burst.

However, it is possible to emulate wrapping burst on a non-wrapping memory by providing relevant addresses within the page or splitting transactions. Bursts larger than the memory page length are chopped into multiple bursts transactions. Due to the alignment requirements, a page boundary is never crossed.

#### 15.4.4.8 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-nonmultiplexed memories or devices is supported with a limited address range of 2 Kbytes.

Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- When the [GPMC\\_CONFIG\[1\]](#) LIMITEDADDRESS bit is set to 1, A26-A11 are not modified during an external memory access. This limits the memory address space to 2K-byte regardless of the memory size.
- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit wide NOR devices do not use GPMC I/O: gpmc\_ad[15:8] for data (they are used for address if needed).
- 16-bit wide NAND devices do not use GPMC I/O: gpmc\_a[25:16].
- 8-bit wide NAND devices do not use GPMC I/O: gpmc\_a[25:16] and GPMC I/O: gpmc\_ad[15:8].

#### CAUTION

Before accessing a chip-select configured with a nonmultiplexed protocol, set the LIMITEDADDRESS bit control.

#### 15.4.4.8.1 GPMC I/O Configuration Setting

---

**NOTE:** In this section and next sections, the *i* in GPMC\_CONFIGx\_i stands for the GPMC chip-select *i* where *i* = 0 to 7.

---

To select a NAND device, program the following register fields:

- [GPMC\\_CONFIG1\\_i\[11:10\]](#) DEVICETYPE field = 0b10
- [GPMC\\_CONFIG1\\_i\[9:8\]](#) MUXADDDATA bit = 0b00

To select an address/data-multiplexed device, program the following register fields:

- [GPMC\\_CONFIG1\\_i\[11:10\]](#) DEVICETYPE field = 0b00
- [GPMC\\_CONFIG1\\_i\[9:8\]](#) MUXADDDATA bit = 0b10

To select an address/address/data-multiplexed device, program the following register fields:

- [GPMC\\_CONFIG1\\_i\[11:10\]](#) DEVICETYPE field = 0b00
- [GPMC\\_CONFIG1\\_i\[9:8\]](#) MUXADDDATA bit = 0b01

To select an address/data-nonmultiplexed device (limited to a 2K-byte address range), program the following register fields:

- [GPMC\\_CONFIG1\\_i\[11:10\]](#) DEVICETYPE field = 0b00
- [GPMC\\_CONFIG1\\_i\[9:8\]](#) MUXADDDATA bit = 0b00
- [GPMC\\_CONFIG\[1\]](#) LIMITEDADDRESS bit = 1

**NOTE:** The `GPMC_CONFIG1[1] LIMITEDADDRESS` bit only applies to address/data-nonmultiplexed devices; it has no effect on other device types (NAND, address/data-multiplexed).

#### 15.4.4.8.2 GPMC CS0 Default Configuration at IC Reset

To ensure a correct external boot with a GPMC access from IC reset time on CS0, several external pins are sampled:

- The `sys_boot[4:0]` pins (device boundary) define the sequence of interfaces and devices to use for booting.
- The `sys_boot[5]` pin defines which group of booting sequences is preferred: memory booting (`sys_boot[5] = 0`) or peripheral booting (`sys_boot[5] = 1`).
- Additional pins are used to configure reset values in the `GPMC_CONFIG1_i` register (where  $i = 0$ ) as detailed below and in [Table 15-221](#):
  - The `bootdevicesize` input pin (at the GPMC boundary) defines the size of the attached device on chip-select 0 and is used to configure the `GPMC_CONFIG1_i[13:12] DEVICESIZE` bits (where  $i = 0$ ). The `BOOT_DEVICE_TYPE` signal is propagated from the system control module (SCM). Its value is fixed for the device at 0x1 at IC reset, which means that only 16-bit memories are supported for booting.
  - The `cs0muxdevice` input pin (at the GPMC boundary) selects whether the attached device to chip-select 0 is an address/data-multiplexed device or not. The input pin is used to configure the `GPMC_CONFIG1_i[9:8] MUXADDDATA` bit (where  $i = 0$ ). The `CS0_MUX_DEVICE` signal is propagated from the SCM. Its value is fixed for the device at 0x2 at IC reset, which means that only address/data-multiplexed memories are supported for booting (that is, in a standalone way from memories connected to CS0).
  - The `bootwaiten` input pin (at the GPMC boundary) enables the monitoring on chip-select 0 of the `WAIT` pin at IC reset release time for read accesses. The input pin is used to configure the `GPMC_CONFIG1_i[22] WAITREADMONITORING` bit (where  $i = 0$ ). The `BOOT_WAIT_ENABLE` signal is propagated from the system control module (SCM). When `sys_boot[5:0] = 0b11 1111`, the `BOOT_WAIT_ENABLE` signal is activated, causing the wait pin to be monitored for read accesses.
  - The `bootwaitselect` input pin selects the `WAIT` signal at IC reset release time between `WAIT0` input pin, `WAIT1` input pin or `WAIT2` input pin. At IC reset release time, these three pins have different polarity.

**Table 15-221. Boot Control Interface Input Signals Description**

Signal Name	Width	Description
<code>bootdevicesize</code>	2	Size of the device attached on CS0 0b00: 8-bit 0b01: 16-bit 0b10: Reserved 0b11: Reserved
<code>cs0muxdevice</code>	2	Multiplexing mode of the device on CS0 0b00: Nonmultiplexed device on CS0 0b01: AAD-multiplexed device on CS0 (address-address-data) 0b10: Address/Data-multiplexed device on CS0 0b11: Reserved
<code>bootwaiten</code>	1	Wait monitoring on CS0 at IC reset release time for read accesses 0: Wait pin is not monitored 1: Wait pin is monitored
<code>bootwaitselect</code>	1	Selection of the wait pin 0: WAIT0 input pin 1: WAIT1 input pin 2: WAIT2 input pin

### CAUTION

Using the internal boot code, the entire CS0 configuration can be modified before the first CS0 access. This modification of internal boot code is necessary for two external devices:

- NAND device attached to CS0
- Nonmultiplexed 2 Kbytes address range device attached to CS0

At reset time, the IC may boot from the internal ROM.

Reset values of the timing control parameters are defined to cope with direct boot on address and data multiplexed NOR Flash device, on non-multiplexed NOR Flash device or on any asynchronous device with large timing margins assuming a low GPMC\_FCLK frequency (for example, 19.2Mhz) at boot time.

For a multiplexed access, the address 16 low-order bits are presented onto gpmc\_ad[15:0] while the high-order bits are presented both onto gpmc\_a[26:16]. If the external chip interface to the memories uses a 16-bit data bus, the high-order address bits are sampled on the address bus.

The reset values of timing parameters used at boot time are:

- CSONTIME = 1
- CSRDOFFTIME = 16
- ADVONTIME = 4
- ADVRDOFFTIME = 5
- OEONTIME = 6
- OEOFFTIME = 16
- RDACCESSTIME = 15
- RDCYCLETIME = 17

For an AAD-multiplexed access, all address bits are passed onto the data bus using two nADV rising edge. The first rising edge latches the address MSB down to bit 17 while the second rising edge latches address bits 16 down to 1. This configuration is only used for 16-bit memories.

The reset values of these timing parameters used at boot time are:

- ADVAADMUXONTIME = 1
- ADVAADMUXRDOFFTIME = 2
- OEAADMUXONTIME = 1
- OEAADMUXRDOFFTIME = 3

#### 15.4.4.9 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file should be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). [Section 15.4.7, GPMC Register Manual](#) provides the GPMC register locations. For the map of GPMC memory locations, see [Chapter 2, Memory Mapping](#).

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

##### 15.4.4.9.1 Chip-Select Base Address and Region Size

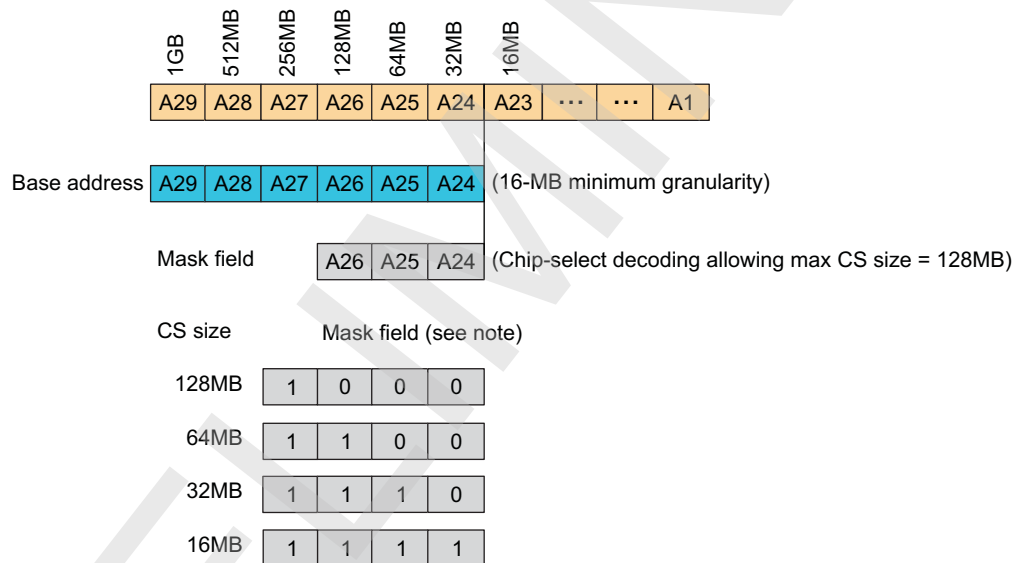

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 1 Gbyte contiguous address space. For details, see [Chapter 2, Memory Mapping](#).

The GPMC 1G byte address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable CS size. The CS size is programmable from 16M bytes to 128M bytes (must be a power-of-2) and is defined by the mask field. Attached memory smaller than the programmed CS region size is accessed through the entire CS region (aliasing).

Each chip-select has a 6-bit base address encoding and a 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-2 address value. During access decoding, the register base address value is used for address comparison with the address-bit line mapping as described in [Figure 15-55](#) (with A0 as the device system byte-address line). Base address is programmed through the `GPMC_CONFIG7_i[5:0]` BASEADDRESS bit field
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The register mask value must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the `GPMC_CONFIG7_i[11:8]` MASKADDRESS bit field.

**Figure 15-55. Chip-Select Address Mapping and Decoding Mask**

gpmc-006

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the `GPMC_CONFIG7_i[6]` CSVALID bit (where *i* stands for the GPMC chip-select value, *i* = 0 to 3). In addition, a chip-select configuration can only be disabled if there is no ongoing access to that chip-select. This requires activity monitoring of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of chip-selects overlapping, an error is generated and no access will occur on either chip-select.

Chip-select 0 is the only chip-select region enabled after either a power-up or a GPMC reset.

### CAUTION

Although the GPMC interface can drive up to 4 chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers, to allow the slowest device to maintain the total load on the lines.

#### 15.4.4.9.2 Access Protocol

##### 15.4.4.9.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the [GPMC\\_CONFIG1\\_i\[11:10\]](#) DEVICETYPE parameter (where  $i = 0$  to 3) for:

- Random-access synchronous or asynchronous memory like NOR flash, SRAM
- NAND flash asynchronous devices

---

**NOTE:** For more information about the NAND flash GPMC basic programming model and NAND support, see [Section 15.4.4.13, NAND Device Basic Programming Model](#), and [Section 15.4.4.13.1, NAND Memory Device in Byte or Word 16 Stream Mode](#).

---

##### 15.4.4.9.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the [GPMC\\_CONFIG1\\_i\[13:12\]](#) DEVICESIZE field ( $i = 0$  to 3) to interface with a 16-bit wide device or an 8-bit wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to both the external device data-bus width and little-endian data organization.

---

**NOTE:** The device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for both multiplexed and nonmultiplexed protocol). It limits the use of 8-bit wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8-bit wide or 16-bit wide devices).

---

##### 15.4.4.9.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing ( $\text{DEVICETYPE} = 0b00$ ), an address- and data-multiplexing protocol can be selected through the [GPMC\\_CONFIG1\\_i\[9:8\]](#) MUXADDDATA bit field ( $i = 0$  to 3). The  $\text{nADV}$  signal must be used as the external device address latch control signal. For the associated chip-select configuration,  $\text{nADV}$  assertion and deassertion time and  $\text{nOE}$  assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See [Section 15.4.3, GPMC Integration](#).

---

**NOTE:** This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data multiplexing protocol. See [Section 15.4.4.13, NAND Device Basic Programming Model](#).

---

#### 15.4.4.9.3 External Signals

##### 15.4.4.9.3.1 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external `gpmc_wait` pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal `RDACCESSTIME`, `WRACCESSTIME` and `PAGEBURSTACCESSTIME` wait state generator.

The GPMC features three input wait pins: gpmc\_wait2, gpmc\_wait1 and gpmc\_wait0. These pins allow control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The [GPMC\\_CONFIG1\\_i\[17:16\]](#) WAITPINSELECT field (i = 0 to 3) selects which input gpmc\_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the [GPMC\\_CONFIG](#) register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

The GPMC access engine can be configured per CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The [GPMC\\_CONFIG1\\_i\[22\]](#) WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The [GPMC\\_CONFIG1\\_i\[21\]](#) WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC\_CLK clock, depending on the access type: synchronous or asynchronous (the [GPMC\\_CONFIG1\\_i\[29\]](#) READTYPE and [GPMC\\_CONFIG1\\_i\[27\]](#) WRITETYPE bits).

#### 15.4.4.9.3.1.1 Wait Monitoring During an Asynchronous Read Access

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

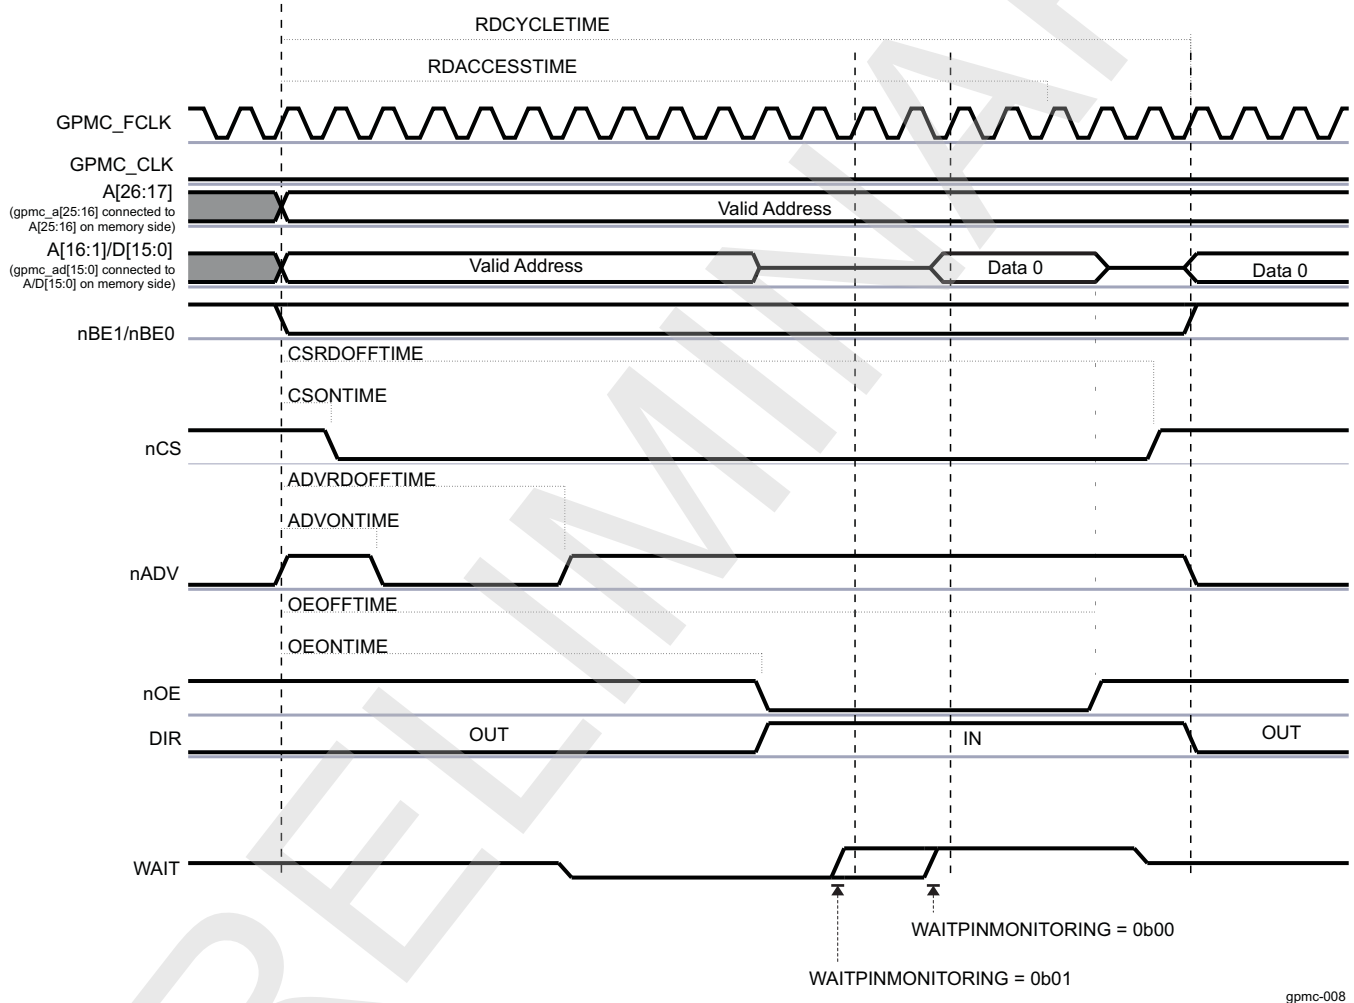

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the [GPMC\\_CONFIG1\\_i\[19:18\]](#) WAITMONITORINGTIME field (i = 0 to 3).

**NOTE:**

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC\_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC\_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 15-56 shows wait behavior during an asynchronous single read access.

**Figure 15-56. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)**

**NOTE:** The WAIT signal is active low. `GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME = 0b00`, or `0b01`.

**15.4.4.9.3.1.2 Wait Monitoring During an Asynchronous Write Access**

When wait-pin monitoring is enabled for write accesses (`GPMC_CONFIG1_i[21] WAITWRITEMONITORING` bit = `0x1`), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the `GPMC_CONFIG1_i[19:18]` WAITMONITORINGTIME fields ( $i = 0$  to 3).

**NOTE:**

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC\_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, `GPMC_CONFIG1_i[1:0]` GPMCFCLKDIVIDER is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.

#### 15.4.4.9.3.1.3 Wait Monitoring During a Synchronous Read Access

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC\_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC\_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the `GPMC_CONFIG1_i[19:18]` WAITMONITORINGTIME field (where  $i = 0$  to 3), and is expressed as a number of GPMC\_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled (`GPMC_CONFIG1_i[22]` WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

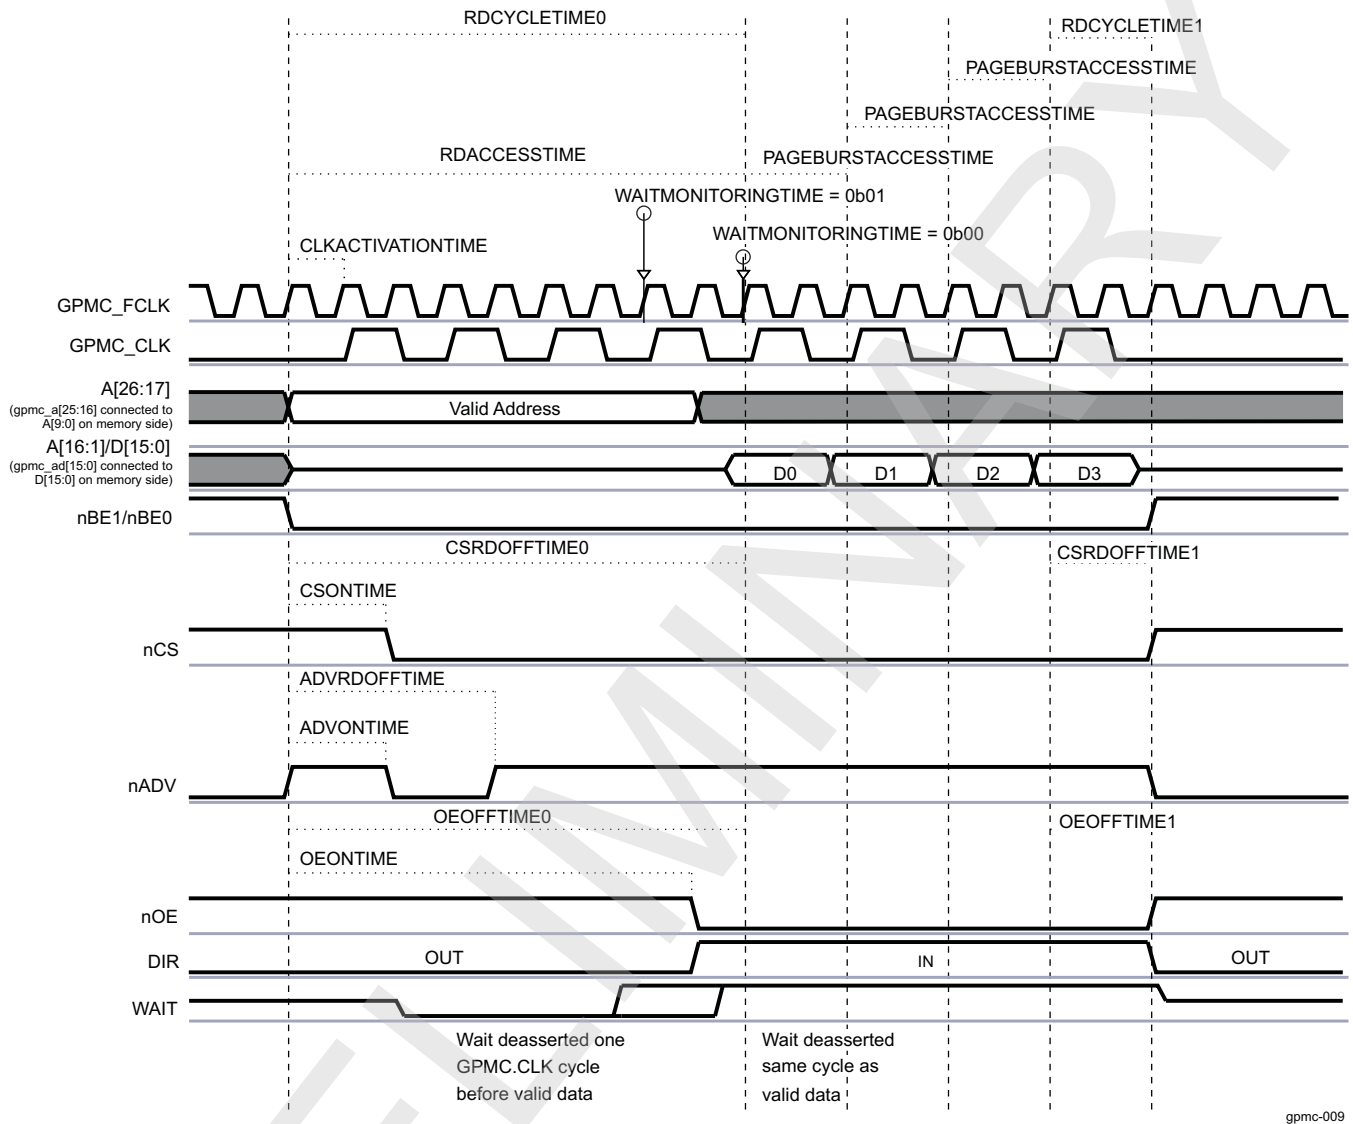

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 ( at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC\_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 15-57 shows wait behavior during a synchronous read burst access.

Figure 15-57. Wait Behavior During a Synchronous Read Burst Access

gpmc-009

**NOTE:** The WAIT signal is active low.  $WAITMONITORINGTIME = 00, 01$ .

#### 15.4.4.9.3.1.4 Wait Monitoring During a Synchronous Write Access

During synchronous accesses with wait-pin monitoring enabled (the  $WAITWRITEMONITORING$  bit), the wait pin is captured synchronously with  $GPMC\_CLK$ , using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with  $WRACCESSTIME$  to delay the effective memory device  $GPMC\_CLK$  capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At  $WRACCESSTIME$  completion if  $WAITMONITORINGTIME = 0$
- In the  $WAITMONITORINGTIME \times (GPMCFCLKDIVIDER + 1)$   $GPMC\_FCLK$  cycles before  $WRACCESSTIME$  completion if  $WAITMONITORINGTIME$  not equal to 0.

Wait-monitoring pipelining definition applies to whole burst accesses:

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

---

**NOTE:** Wait monitoring is supported for all configurations except for [GPMC\\_CONFIG1\\_i\[19:18\]](#) WAITMONITORINGTIME = 0x0 (where i = 0 to 3) for write bursts with a clock divider of 1 or 2 ([GPMC\\_CONFIG1\\_i\[1:0\]](#) GPMCFCLKDIVIDER field equal to 0x0 or 0x1 respectively).

---

#### 15.4.4.9.3.1.5 WAIT with NAND Device

For details about the use of the wait pin for communication with a NAND flash external device, see [Section 15.4.4.13.2, NAND Device-Ready Pin](#).

#### 15.4.4.9.3.1.6 Idle Cycle Control Between Successive Accesses

##### 15.4.4.9.3.1.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the nCS/nOE de-assertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after nCS or nOE de-assertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the [GPMC\\_CONFIG6\\_i\[3:0\]](#) BUSTURNAROUND bit field (where i = 0 to 3).

After a read access to a chip-select with a non zero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

---

**NOTE:** Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus will not have enough time to go into high-impedance even though it could be driven with the same value before bus turnaround timing.

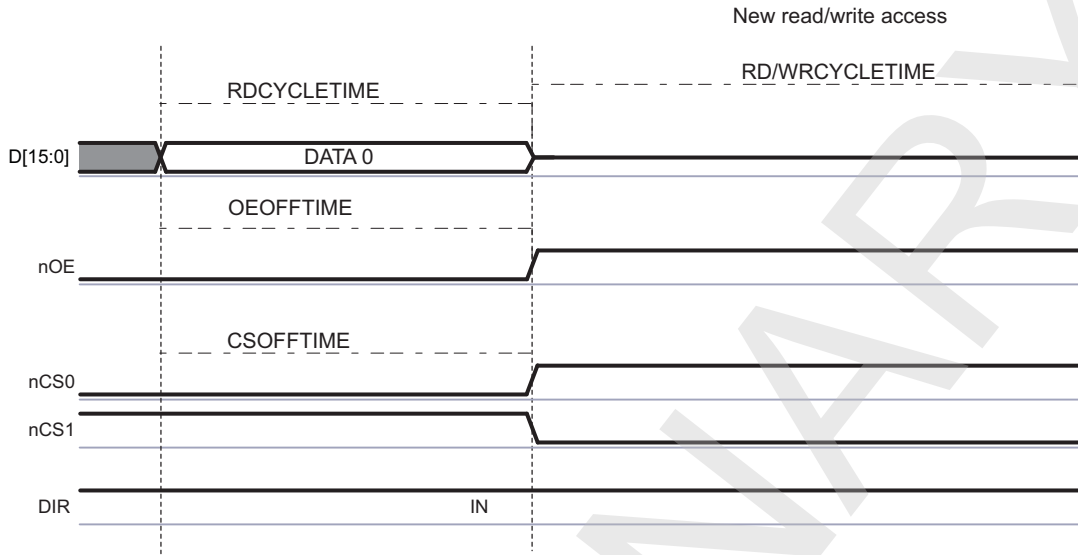

---

BUSTURNAROUND delay runs in parallel with [GPMC\\_CONFIG6\\_i\[3:0\]](#) CYCLE2CYCLEDELAY delays. It should be noted that BUSTURNAROUND is a timing parameter for the ending chip-select access while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access. See [Figure 15-58](#) to [Figure 15-60](#).

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

**Figure 15-58. Read to Read for an Address-Data Multiplexed Device, on Different CS, without Bus Turnaround (nCS0 attached to a fast device)**

gpmc-049

**Figure 15-59. Read to Read / Write for an Address-Data Multiplexed Device, on Different CS, with Bus Turnaround**

gpmc-050

**Figure 15-60. Read to Read / Write for a Address-Data or AAD-multiplexed device, on the Same CS, with Bus Turnaround**

#### 15.4.4.9.3.1.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The [GPMC\\_CONFIG6\\_i\[7\]](#) CYCLE2CYCLESAMECSEN bit ( $i = 0$  to 3) enables insertion of a minimum number of GPMC\_FCLK cycles, defined by the [GPMC\\_CONFIG6\\_i\[11:8\]](#) CYCLE2CYCLEDELAY field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used ([GPMC\\_CONFIG1\\_i\[30\]](#) READMULTIPLE = 0 or [GPMC\\_CONFIG1\\_i\[28\]](#) WRITEMULTIPLE = 0).

All control signals are kept in their default states during these idle GPMC\_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

#### 15.4.4.9.3.1.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals ( $nCS$ ,  $nADV/ALE$ ,  $nBE0/CLE$ ,  $nOE/RE$ ,  $nWE$ ) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals ( $WE$ ,  $OE/RE$ ) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If [GPMC\\_CONFIG6\\_i\[6\]](#) CYCLE2CYCLEDIFFCSEN is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC\_FCLK cycles.

**NOTE:** CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in GPMC\_CONFIG6<sub>i</sub> registers to respectively get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. It should be noted that BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, since bus turnaround does not apply to all access types. See Section 15.4.4.9.3.1.6.1, *Bus Turnaround (BUSTURNAROUND)* for more details on bus turnaround.

Table 15-222 describes the configuration required for idle cycle insertion.

**Table 15-222. Idle Cycle Insertion Configuration**

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

**15.4.4.9.3.1.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)**

All access-timing parameters can be multiplied by 2 by setting the GPMC\_CONFIG1<sub>i</sub>[4] TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select value, i = 0 to 3). Increasing all access timing parameters allows support of slow devices.

**15.4.4.9.3.2 gpmc\_io\_dir Pin**

The gpmc\_io\_dir pin is used to control I/O direction on the GPMC data bus gpmc\_ad[15:0]. Depending on top-level pad multiplexing, this signal can be output and used externally to the device, if required.

The `gpmc_io_dir` pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the `gpmc_io_dir` pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the `gpmc_io_dir` pin goes from OUT to IN at `nOE` assertion time and stays IN until:

- BUSTURNAROUND is enabled:
  - The `gpmc_io_dir` pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled:
  - After an asynchronous read access, the `gpmc_io_dir` pin goes from IN to OUT at `RDACCESSTIME + 1 GPMC_FCLK` cycle or when `RDCYCLETIME` completes, whichever occurs last.
  - After a synchronous read access, the `gpmc_io_dir` pin goes from IN to OUT at `RDACCESSTIME + 2 GPMC_FCLK` cycles or when `RDCYCLETIME` completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the `gpmc_io_dir` pin is OUT (see [Section 15.4.4.10.10, Bus Keeping Support](#)).

In nonmultiplexed devices, the `gpmc_io_dir` pin stays IN between two successive read accesses to prevent unnecessary toggling (nonmultiplexed 16-bit wide devices support is limited to 2 Kbytes).

#### 15.4.4.9.3.3 Reset

No reset signal is sent to the external memory device by the GPMC. For more information about external-device reset, see [Chapter 3, Power, Reset, and Clock Management](#).

The PRCM module provides an input pin, `global_rst_n`, to the GPMC:

- The `global_rst_n` pin is activated during device warm reset and cold reset.
- The `global_rst_n` pin initializes the internal state-machine and the internal configuration registers.

#### 15.4.4.9.3.4 Write Protect Signal (nWP)

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory.

The `gpmc_nwp` output pin value is controlled through the `GPMC_CONFIG[4]` WRITEPROTECT bit, which is common to all CS.

#### 15.4.4.9.3.5 Byte Enable (nBE1/nBE0)

Byte enable signals (`nBE1/nBE0`) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

#### 15.4.4.9.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the `GPMC_ERR_TYPE` register and the address of the illegal access is stored in the `GPMC_ERR_ADDRESS` register. The GPMC only keeps the first error abort information until the `GPMC_ERR_TYPE` register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the `GPMC_ERR_TYPE[0]` ERRORVALID bit.

- `ERRORNOTSUPPADD` occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1 Kbyte.
- `ERRORNOTSUPPMCMD` occurs when an unsupported command request is decoded at the L3 interconnect interface.

- **ERRORTIMEOUT:** A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the [GPMC\\_TIMEOUT\\_CONTROL](#) register and enabled with the [GPMC\\_TIMEOUT\\_CONTROL\[0\]](#) TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at interconnect level.

#### 15.4.4.10 Timing Setting

The GPMC offers the maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information on GPMC\_CLK and GPMC\_FCLK see [Section 15.4.4.10.6](#), [GPMC\\_CLK](#).

---

**NOTE:** In the following sections, the start access time refer to the time at which the access begins.

---

##### 15.4.4.10.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The [GPMC\\_CONFIG5\\_i\[4:0\]](#) RDCYCLETIME and [GPMC\\_CONFIG5\\_i\[12:8\]](#) WRCYCLETIME fields ( $i = 0$  to 3) define the address bus and byte enables valid times for read and write accesses. To ensure a correct duty cycle of GPMC\_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC\_FCLK cycles and must be multiples of the GPMC\_CLK cycle. RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 through [GPMC\\_CONFIG1\\_i\[4\]](#) TIMEPARAGRANULARITY.

When either RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (nCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

If no inactive cycles are required between successive accesses to the same or to a different chip-select ([GPMC\\_CONFIG6\\_i\[7\]](#) CYCLE2CYCLESAMECSSEN = 0 or [GPMC\\_CONFIG6\\_i\[6\]](#) CYCLE2CYCLEDIFFCSSEN = 0, where  $i = 0$  to 3), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses, that is, [CYCLE2CYCLESAMECSSEN](#) = 1 or [CYCLE2CYCLEDIFFCSSEN](#) = 1, the control signals are forced to their respective default reset values for the number of GPMC\_FCLK cycles defined in [CYCLE2CYCLEDELAY](#):

##### 15.4.4.10.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The [GPMC\\_CONFIG2\\_i\[3:0\]](#) CSONTIME field (where  $i = 0$  to 3) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

[GPMC\\_CONFIG2\\_i\[12:8\]](#) CSRDOFFTIME (read access) and [GPMC\\_CONFIG2\\_i\[20:16\]](#) CSWROFFTIME (write access) bit fields define the nCS signal deassertion time relative to start access time.

CSONTIME, CSRDOFFTIME and CSWROFFTIME parameters are applicable to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte enable hold time after chip-select deassertion.

nCS signal transitions as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME can be delayed by half a GPMC\_FCLK period by enabling the [GPMC\\_CONFIG2\\_i\[7\]](#) CSEXTRADELAY bit. This half of a GPMC\_FCLK period provides more granularity on the nCS assertion and deassertion time to guarantee proper setup and hold time relative to GPMC\_CLK. CSEXTRADELAY is especially useful in configurations where GPMC\_CLK and GPMC\_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters controlling nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

#### **15.4.4.10.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)**

The [GPMC\\_CONFIG3\\_i\[3:0\]](#) ADVONTIME field (where i = 0 to 3) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

[GPMC\\_CONFIG3\\_i\[12:8\]](#) ADVRDOFFTIME (read access) and [GPMC\\_CONFIG3\\_i\[20:16\]](#) ADVWROFFTIME (write access) bit fields define the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte enable valid hold time control after nADV/ALE de-assertion. ADVRDOFFTIME and ADVWROFFTIME are applicable to both synchronous and asynchronous modes.

nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by half a GPMC\_FCLK period by enabling the [GPMC\\_CONFIG3\\_i\[7\]](#) ADVEXTRADELAY bit. This half of a GPMC\_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to guarantee proper setup and hold time relative to GPMC\_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC\_CLK and GPMC\_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

[GPMC\\_CONFIG3\\_i\[6:4\]](#) ADVAADMUXONTIME, [GPMC\\_CONFIG3\\_i\[26:24\]](#) ADVAADMUXRDOFFTIME, and [GPMC\\_CONFIG3\\_i\[30:28\]](#) ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. It is the user responsibility to make sure ADVAADMUXxxOFFTIME is programmed to a value lower than or equal to ADVxxOFFTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high nADV pulse is needed between the two AAD-mux address phases, which is the typical case in synchronous mode. In this configuration, nADV is kept low until it reaches the correct ADVxxOFFTIME.

See [Section 15.4.4.13, NAND Access Description](#) for more details on ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME, ADVAADMUXWROFFTIME usage for CLE and ALE (Command / Address Latch Enable) usage for a NAND Flash interface.

#### 15.4.4.10.4 **nOE/nRE: Output Enable / Read Enable Signal Control Assertion / Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)**

The [GPMC\\_CONFIG4\\_i\[3:0\]](#) OEONTIME field (where i = 0 to 3) defines the nOE/nRE signal assertion time relative to start access time. It is applicable only to read accesses.

The [GPMC\\_CONFIG4\\_i\[12:8\]](#) OEOFFTIME field defines the nOE/nRE signal deassertion time relative to start access time. It is applicable only to read accesses. nOE/nRE is not asserted during a write cycle.

OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME parameters are applicable to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte enable valid hold time control after nOE/nRE assertion.

OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. It is the user responsibility to make sure OEAADMUXOFFTIME is programmed to a value lower than OEONTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME shall never be equal to OEONTIME because the AAD-mux protocol requires a second address phase with the nOE signal de-asserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME can be delayed by half a GPMC\_FCLK period by enabling the [GPMC\\_CONFIG4\\_i\[7\]](#) OEEXTRADELAY bit. This half of a GPMC\_FCLK period provides more granularity on nOE/RE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC\_CLK. If enabled, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than nOE/RE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

---

**NOTE:** When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

---

#### 15.4.4.10.5 **nWE: Write Enable Signal Control Assertion / Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)**

The [GPMC\\_CONFIG4\\_i\[19:16\]](#) WEONTIME field (where i = 0 to 3) defines the nWE signal-assertion time relative to start access time. The [GPMC\\_CONFIG4\\_i\[28:24\]](#) WEOFFTIME field defines the nWE signal-deassertion time relative to start access time. These bit fields only apply to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by half a GPMC\_FCLK period by enabling the [GPMC\\_CONFIG4\\_i\[23\]](#) WEEXTRADELAY bit. This half of a GPMC\_FCLK period provides more granularity on nWE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC\_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

#### 15.4.4.10.6 **GPMC\_CLK**

GPMC\_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC\_CLK clock frequency is the GPMC\_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the [GPMC\\_CONFIG1\\_i\[1:0\]](#) GPMCFCLKDIVIDER bit field (where i = 0 to 3), with a guaranteed 50-percent duty cycle.

- The GPMC\_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The [GPMC\\_CONFIG1\\_i\[26:25\]](#) CLKACTIVATIONTIME field ( $i = 0$  to 3) defines the number of GPMC\_FCLK cycles from start access time to GPMC\_CLK activation.
- The GPMC\_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC\_CLK clock is kept low when access is defined as asynchronous.

**CAUTION**

When cycle time completes, the GPMC\_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC\_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.

**NOTE:** To ensure a correct external clock cycle, the following rules must be applied:

- $(RDCYCLETIME \text{ CLKACTIVATIONTIME})$  must be a multiple of  $(GPMCFCLKDIVIDER + 1)$ .
- The PAGEBURSTACCESSTIME value must be a multiple of  $(GPMCFCLKDIVIDER + 1)$ .

**15.4.4.10.7 GPMC\_CLK and Control Signals Setup and Hold**

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC\_CLK edge can be controlled in the following ways:

- For the GPMC\_CLK signal, the [GPMC\\_CONFIG1\\_i\[26:25\]](#) CLKACTIVATIONTIME field ( $i = 0$  to 3) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC\_CLK allows setup and hold control of control-signal assertion and deassertion times.
- When GPMC\_CLK runs at the GPMC\_FCLK frequency so that GPMC\_CLK edge and control-signal transitions refer to the same GPMC\_FCLK edge, the control-signal transitions can be delayed by half of a GPMC\_FCLK period to provide minimum setup and hold times. This half-GPMC\_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC\_FCLK cycle.

**15.4.4.10.8 Access Time (RDACCESSTIME / WRACCESSTIME)**

The read access time and write access time durations can be programmed independently through [GPMC\\_CONFIG5\\_i\[20:16\]](#) RDACCESSTIME and [GPMC\\_CONFIG6\\_i\[28:24\]](#) WRACCESSTIME ( $i = 0$  to 3). This allows nOE and GPMC data capture timing parameters to be independent of nWE and memory device data capture timing parameters. RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through [GPMC\\_CONFIG1\\_i\[4\]](#) TIMEPARAGRANULARITY.

**15.4.4.10.8.1 Access Time on Read Access**

In asynchronous read mode, for single and paged accesses, [GPMC\\_CONFIG5\\_i\[20:16\]](#) RDACCESSTIME field ( $i = 0$  to 3) defines the number of GPMC\_FCLK cycles from start access time to the GPMC\_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC\_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC\_FCLK cycles from start access time to the GPMC\_FCLK rising edge corresponding to the GPMC\_CLK rising edge used for the first data capture.

GPMC\_CLK which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. GPMC\_CONFIG5\_i[4:0] RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally retimed GPMC\_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC\_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see [Section 15.4.4.9.3.1, Chip-Select Base Address and Region Size](#).

#### **15.4.4.10.8.2 Access Time on Write Access**

In asynchronous write mode, the GPMC\_CONFIG6\_j[28:24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc\_wait pin is at a valid state two GPMC\_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see [Section 15.4.4.9.3.1, Chip-Select Base Address and Region Size](#).

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC\_FCLK cycles from start access time to the GPMC\_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC\_CLK edge for a synchronous write access. For details about wait monitoring, see [Section 15.4.4.9.3.1, Chip-Select Base Address and Region Size](#).

#### **15.4.4.10.9 Page Burst Access Time (PAGEBURSTACCESSTIME)**

GPMC\_CONFIG5\_i[27:24] PAGEBURSTACCESSTIME bit field (i = 0 to 3) can be set with a granularity of 1 or 2 through GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY.

##### **15.4.4.10.9.1 Page Burst Access Time on Read Access**

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC\_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC\_FCLK edge on read access. For details about wait monitoring, see [Section 15.4.4.9.3.1, Chip-Select Base Address and Region Size](#).

##### **15.4.4.10.9.2 Page Burst Access Time on Write Access**

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC\_CLK edge in synchronous write mode. For details about wait monitoring, see [Section 15.4.4.9.3.1, Chip-Select Base Address and Region Size](#).

#### **15.4.4.10.10 Bus Keeping Support**

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completion time to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

#### 15.4.4.11 NOR Access Description

For each chip-select configuration, the read access can be specified as either asynchronous or synchronous access through the `GPMC_CONFIG1_j[29]` READTYPE bit ( $i = 0$  to 3). For each chip-select configuration, the write access can be specified as either synchronous or asynchronous access through the `GPMC_CONFIG1_j[27]` WRITETYPE bit ( $i = 0$  to 3).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to `GPMC_FCLK`. The primary difference of synchronous mode is the availability of a configurable clock interface (`GPMC_CLK`) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For details about asynchronous and synchronous access, see the descriptions of `GPMC_CLK`, `RdAccessTime`, `WrAccessTime`, and wait-pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

---

**NOTE:** The address bus and `nBE[1:0]` are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

---

##### 15.4.4.11.1 Asynchronous Access Description

This section describes:

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations `GPMC_CLK` is not provided outside the GPMC and is kept low.

15.4.4.11.1.1 Access on Address/Data Multiplexed Devices

15.4.4.11.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 15-61 shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 15-61. Asynchronous Single Read on an Address/Data-Multiplexed Device

See Section 15.4.5.6.1, *GPMC Timing Parameters Formulas* for formulas to calculate timing parameters.

Table 15-256 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits gpmc\_a[25:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC\_CONFIG2\_i[3:0] CS ONTIME field. It controls the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC\_CONFIG2\_i[12:8] CSRD OFFTIME field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC\_CONFIG3\_i[3:0] ADV ONTIME field.
  - nADV deassertion time is controlled by the GPMC\_CONFIG3\_i[12:8] ADV RD OFFTIME field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC\_CONFIG4\_i[3:0] OE ONTIME field.
  - nOE deassertion time is controlled by the GPMC\_CONFIG4\_i[12:8] OE OFFTIME field.

- Read data is latched when RDACCESSTIME completes. Access time is defined in the [GPMC\\_CONFIG5\\_i\[20:16\]](#) RDACCESSTIME field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the [GPMC\\_CONFIG5\\_i\[4:0\]](#) RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see [Section 15.4.4.11.5, System Burst Versus External Device Burst Support](#).

Between two successive accesses, if an nCS pulse is needed:

- The [GPMC\\_CONFIG6\\_i\[11:8\]](#) CYCLE2CYCLEDELAY field can be programmed with [GPMC\\_CONFIG6\\_i\[7\]](#) CYCLE2CYCLESAMECSEN enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

**Figure 15-62. Two Asynchronous Single Read Accesses on an Address/Data Multiplexed Device (32-bit read split into 2 x 16-bit read)**

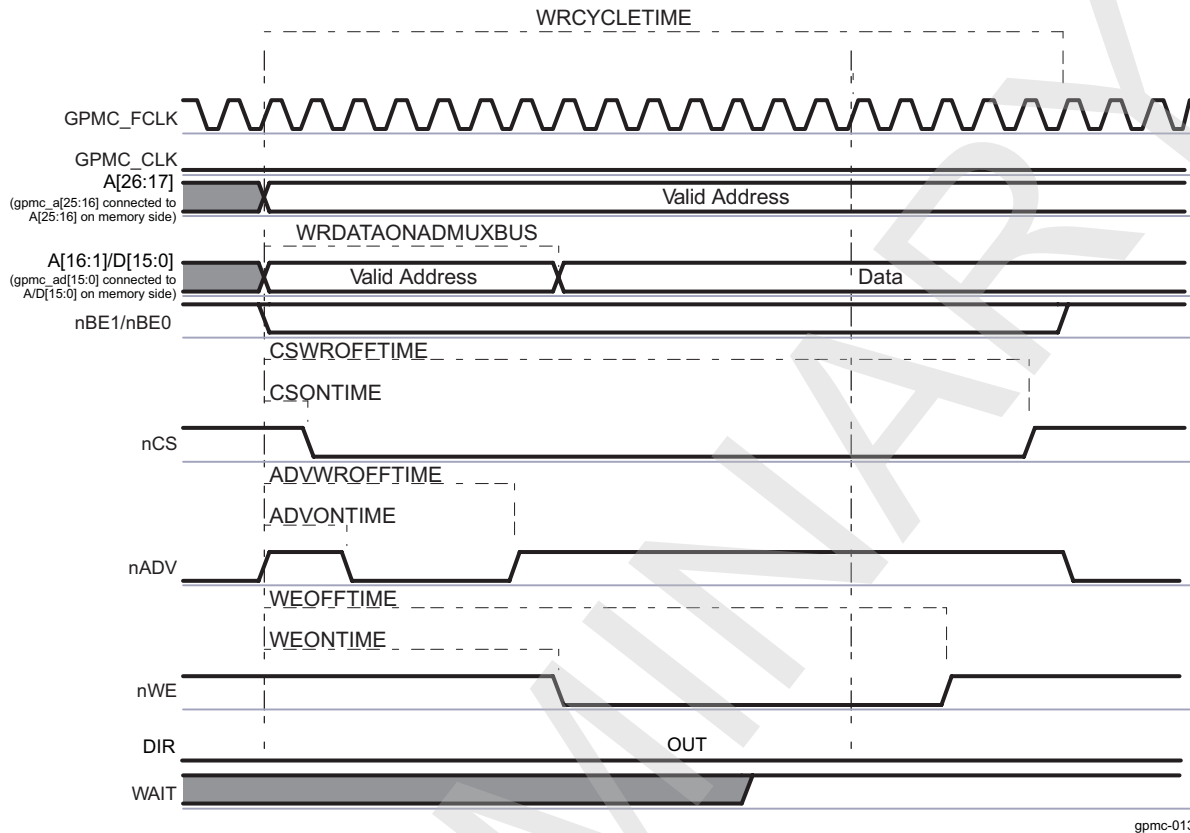

gpmc-044

#### 15.4.4.11.1.2 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

Figure 15-63 shows an asynchronous single write operation on an address/data-multiplexed device.

**Figure 15-63. Asynchronous Single Write on an Address/Data-Multiplexed Device**

gpmc-013

See [Section 15.4.5.6.1, GPMC Timing Parameters Formulas](#) for formulas to calculate timing parameters.

[Table 15-256](#) lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see [Section 15.4.4.9.2.3, Address/Data-Multiplexing Interface](#).

The nCS, and nADV signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the [GPMC\\_CONFIG4\\_i\[19:16\] WEONTIME](#) field.
  - nWE deassertion time is controlled by the [GPMC\\_CONFIG4\\_i\[28:24\] WEOFFTIME](#) field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the [GPMC\\_CONFIG5\\_i\[12:8\] WRCYCLETIME](#) parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a [GPMC\\_CONFIG6\\_i\[19:16\] WRDATAONADMUXBUS](#) time.

**NOTE:** Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See [Section 15.4.4.10.10, Bus Keeping Support](#).

**15.4.4.11.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device**

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

If `GPMC_CONFIG1_i[28]` `WRITEMULTIPLE` is enabled (0x1) with `GPMC_CONFIG1_i[27]` `WRITETYPE` as asynchronous (0x0), the GPMC processes single asynchronous accesses.

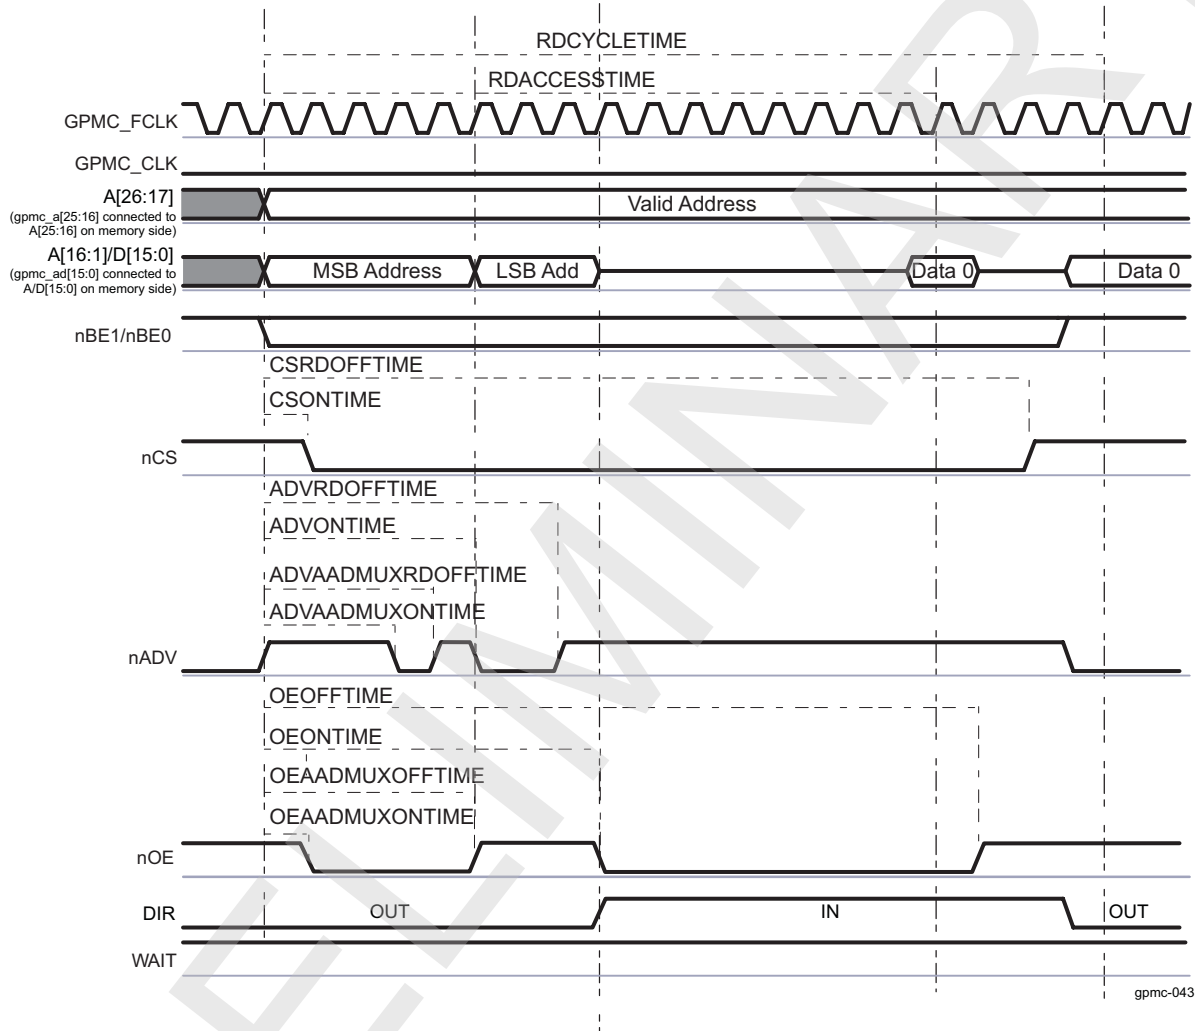

For accesses on non-multiplexed devices refer to [Section 15.4.4.11.3, Asynchronous and Synchronous Accesses in Nonmultiplexed Mode](#).

15.4.4.11.1.2 Access on Address/Address/Data Multiplexed Devices

15.4.4.11.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 15-64 shows an asynchronous single read operation on an AAD-multiplexed device.

Figure 15-64. Asynchronous Single Read on an AAD-Multiplexed Device

See Section 15.4.5.6.1, *GPMC Timing Parameters Formulas* for formulas to calculate timing parameters.

Table 15-256 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS, and DIR signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC\_CONFIG3\_i[6:4] ADVAADMUXONTIME field.
  - nADV first deassertion time is controlled by the GPMC\_CONFIG3\_i[26:24] ADVAADMUXRDOFFTIME field.

- nADV second assertion time is controlled by the [GPMC\\_CONFIG3\\_i\[3:0\]](#) ADVONTIME field.
- nADV second deassertion time is controlled by the [GPMC\\_CONFIG3\\_i\[12:8\]](#) ADVRDOFFTIME field.
- Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the [GPMC\\_CONFIG4\\_i\[6:4\]](#) OEAADMUXONTIME field.
  - nOE first deassertion time is controlled by the [GPMC\\_CONFIG3\\_i\[15:13\]](#) OEAADMUXOFFTIME field.
  - nOE second assertion time is controlled by the [GPMC\\_CONFIG4\\_i\[3:0\]](#) OEONTIME field.
  - nOE second deassertion time is controlled by the [GPMC\\_CONFIG4\\_i\[12:8\]](#) OEOFFTIME field.

#### 15.4.4.11.1.2.2 Asynchronous Single Write Operation on an AAD-Multiplexed Device

Figure 15-65 shows an asynchronous single write operation on an AAD-multiplexed device.

**Figure 15-65. Asynchronous Single Write on an AAD-Multiplexed Device**

See [Section 15.4.5.6.1, GPMC Timing Parameters Formulas](#) for formulas to calculate timing parameters.

[Table 15-256](#) lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for asynchronous single write operation on an address/data-multiplexed device. See [Table 15-247](#).

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
  - nADV first assertion time is controlled by the [GPMC\\_CONFIG3\\_i\[6:4\]](#) ADVAADMUXONTIME field.
  - nADV first deassertion time is controlled by the [GPMC\\_CONFIG3\\_i\[30:28\]](#) ADVAADMUXWROFFTIME field.
  - nADV second assertion time is controlled by the [GPMC\\_CONFIG3\\_i\[3:0\]](#) ADVONTIME field.
  - nADV second deassertion time is controlled by the [GPMC\\_CONFIG3\\_i\[20:16\]](#) ADVWROFFTIME field.
- Output Enable signal nOE is asserted during the address phase of a write transaction:
  - nOE assertion time is controlled by the [GPMC\\_CONFIG4\\_i\[6:4\]](#) OEAADMUXONTIME field.
  - nOE deassertion time is controlled by the [GPMC\\_CONFIG3\\_i\[15:13\]](#) OEAADMUXOFFTIME field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the [GPMC\\_CONFIG6\\_i\[19:16\]](#) WRDATAONADMUXBUS parameter.

#### 15.4.4.11.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If [GPMC\\_CONFIG1\\_i\[28\]](#) WRITEMULTIPLE is enabled (0x1) with [GPMC\\_CONFIG1\\_i\[27\]](#) WRITETYPE as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices refer to [Section 15.4.4.11.3](#), *Asynchronous and Synchronous Accessed in Nonmultiplexed Mode*.

#### 15.4.4.11.2 Synchronous Access Description

This section details read and write synchronous accesses on address/data multiplexed. All information in this section can be applied to any type of memory - non-multiplexed, address and data multiplexed or AAD-multiplexed - with a difference limited to the address phase. For accesses on non-multiplexed devices refer to [Section 15.4.4.11.3](#), *Asynchronous and Synchronous Accessed in Nonmultiplexed Mode*.

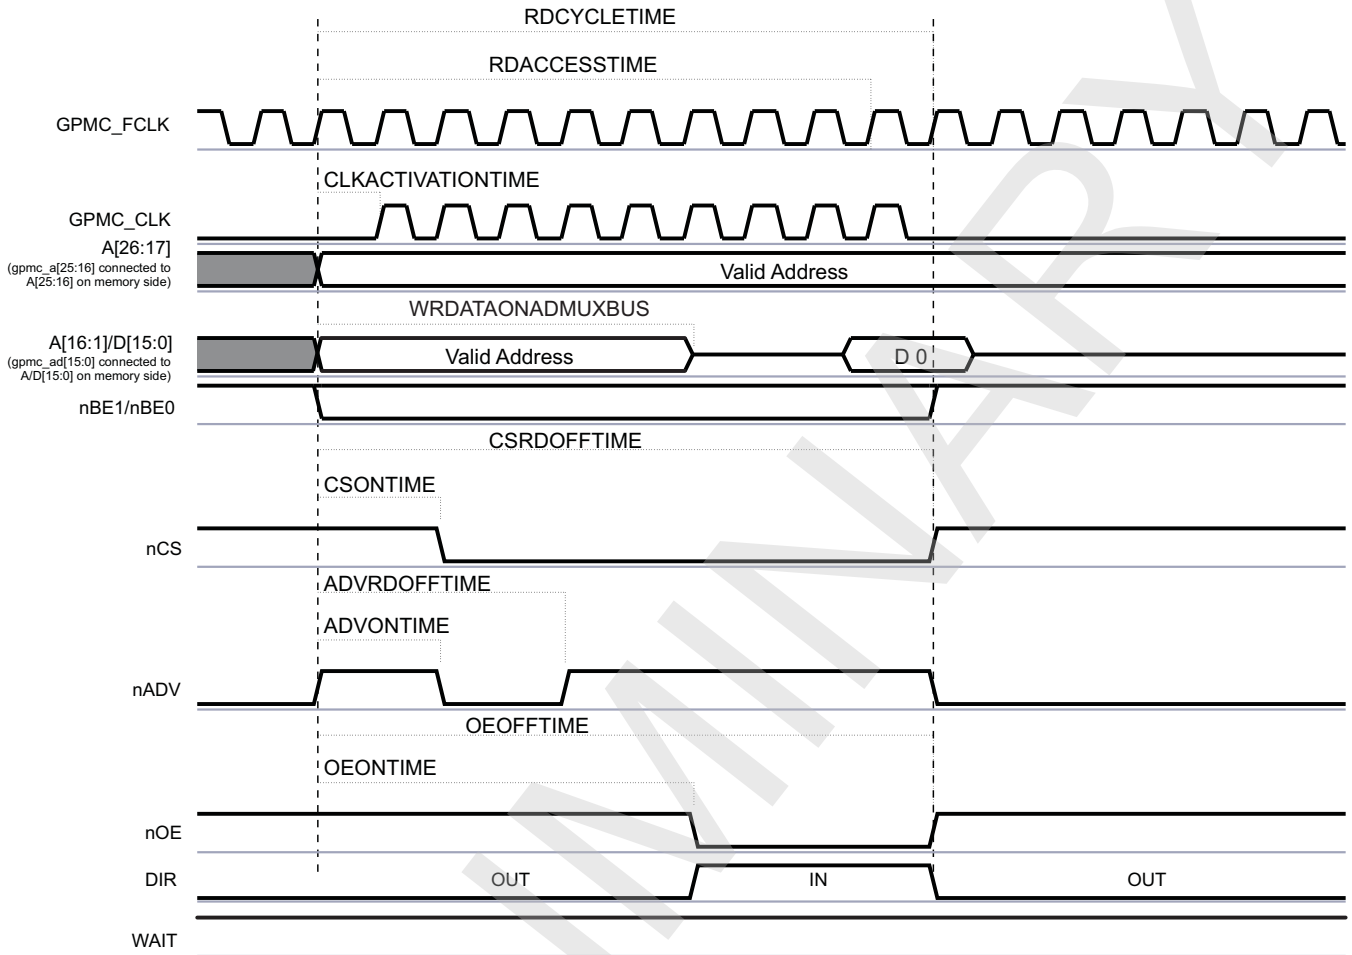

In synchronous operations:

- The GPMC\_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC\_CLK clock is derived from the GPMC\_FCLK clock using the [GPMC\\_CONFIG1\\_i\[1:0\]](#) GPMCFCLKDIVIDER field. In the following section i stands for the chip-select number, i = 0 to 3.
- The [GPMC\\_CONFIG1\\_i\[26:25\]](#) CLKACTIVATIONTIME field specifies that the GPMC\_CLK is provided outside the GPMC 0, 1, or 2 GPMC\_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completion.

#### 15.4.4.11.2.1 Synchronous Single Read

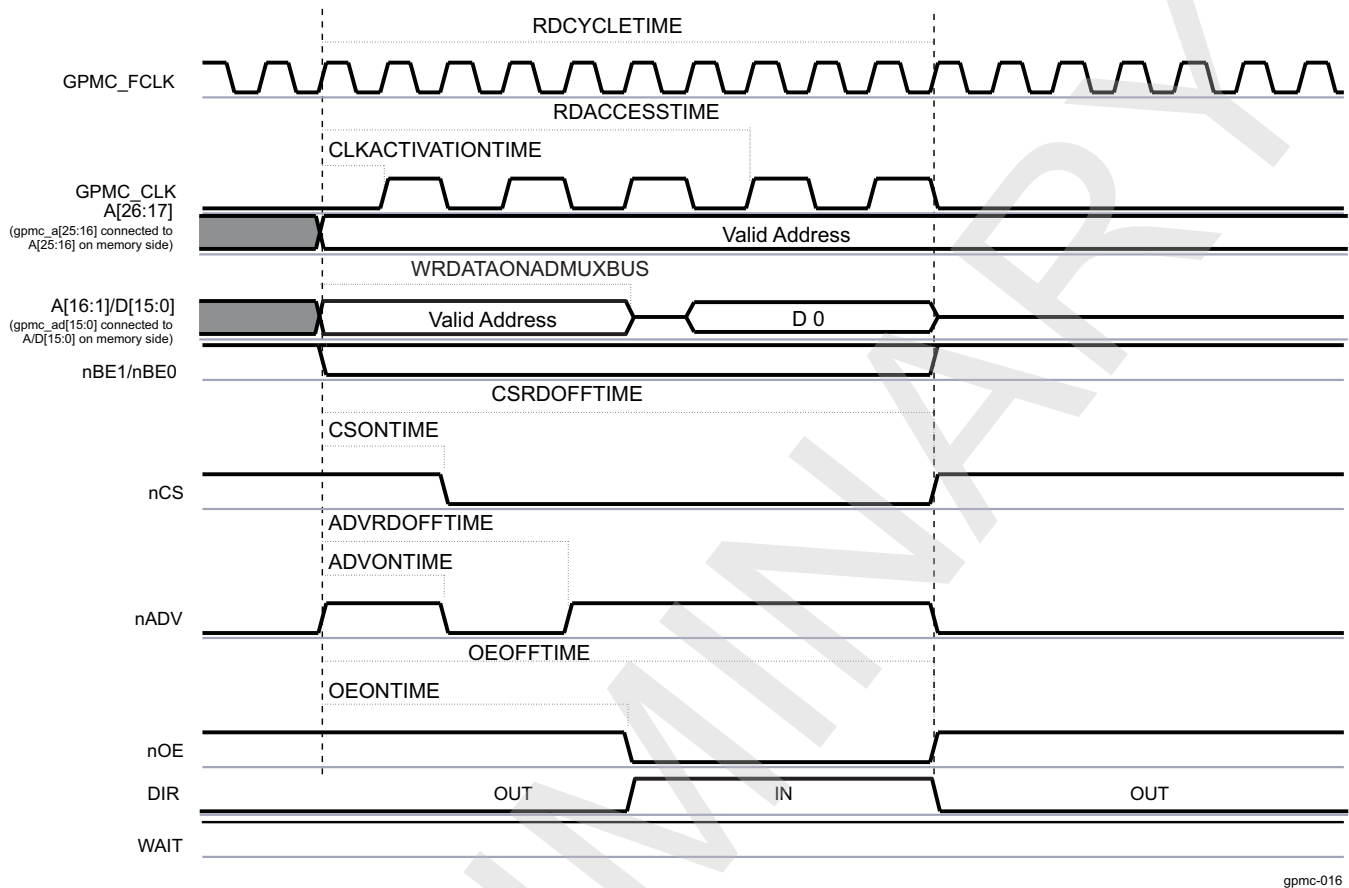

[Figure 15-66](#) and [Figure 15-67](#) show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

**Figure 15-66. Synchronous Single Read (GPMCFCLKDIVIDER = 0)**

gpmc-015

Figure 15-67. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

gpmc-016

See Section 15.4.5.6.1, *GPMC Timing Parameters Formulas* for formulas to calculate timing parameters.

Table 15-256 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC\_CONFIG2\_i[3:0] CS ONTIME field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC\_CONFIG2\_i[12:8] CSRD OFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC\_CONFIG3\_i[3:0] ADV ONTIME field.
  - nADV deassertion time is controlled by the GPMC\_CONFIG3\_i[12:8] ADVRD OFFTIME field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC\_CONFIG4\_i[3:0] OE ONTIME field.
  - nOE deassertion time is controlled by the GPMC\_CONFIG4\_i[12:8] OE OFFTIME field.
- Initial latency for the first read data is controlled by GPMC\_CONFIG5\_i[20:16] RDACCESSTIME or by monitoring the WAIT signal.
- Total access time (GPMC\_CONFIG5\_i[4:0] RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRD OFFTIME.
- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled in the same way as for synchronous single read operation on an address/data-multiplexed device.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the [GPMC\\_CONFIG3\\_i\[6:4\]](#) ADVAADMUXONTIME field.
  - nADV first deassertion time is controlled by the [GPMC\\_CONFIG3\\_i\[26:24\]](#) ADVAADMUXRDOFFTIME field.
  - nADV second assertion time is controlled by the [GPMC\\_CONFIG3\\_i\[3:0\]](#) ADVONTIME field.
  - nADV second deassertion time is controlled by the [GPMC\\_CONFIG3\\_i\[12:8\]](#) ADVRDOFFTIME field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the [GPMC\\_CONFIG4\\_i\[6:4\]](#) OEAADMUXONTIME field.
  - nOE first deassertion time is controlled by the [GPMC\\_CONFIG3\\_i\[15:13\]](#) OEAADMUXOFFTIME field.
  - nOE second assertion time is controlled by the [GPMC\\_CONFIG4\\_i\[3:0\]](#) OEONTIME field.
  - nOE second deassertion time is controlled by the [GPMC\\_CONFIG4\\_i\[12:8\]](#) OEOFFTIME field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 15.4.4.10.10](#), *Bus Keeping Support*.

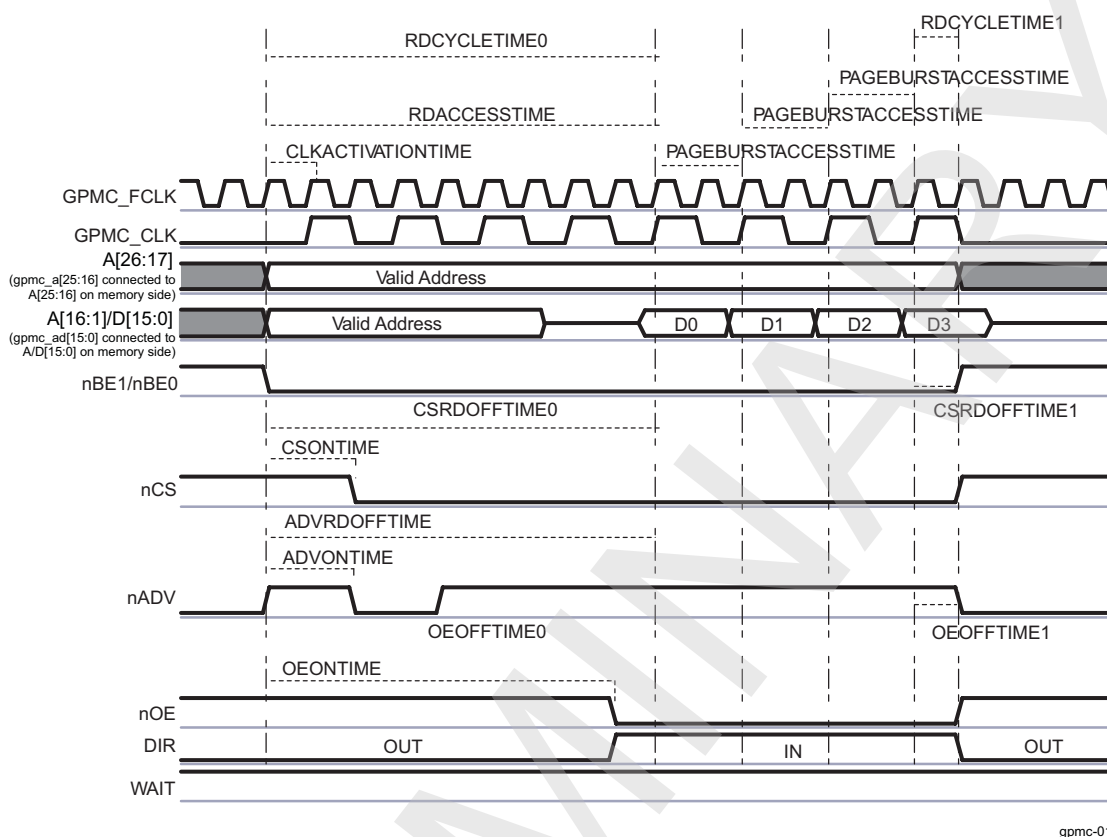

#### 15.4.4.11.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

[Figure 15-68](#) and [Figure 15-69](#) show a synchronous multiple read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

Figure 15-68. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

gpmc-018

**Figure 15-69. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)**

gpmc-019

When [GPMC\\_CONFIG5\\_j\[20:16\]](#) RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to [GPMC\\_CONFIG5\\_j\[27:24\]](#) PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

The nCS, nADV, nOE and DIR signals are controlled in the same way as for synchronous single read operation. See [Table 15-242](#).

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device each one or two GPMC\_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with [GPMC\\_CONFIG1\\_i\[1:0\]](#) GPMCFCLKDIVIDER and the memory-device internal configuration. Depending on the device page length, the GPMC checks device page crossing during a new burst request and purposely insert initial latency (of RDACCESSTIME) when required.

Total access time [GPMC\\_CONFIG5\\_j\[4:0\]](#) RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from nCS deassertion. In [Figure 15-69](#), RDCYCLETIME programmed value equals to RDCYCLETIME0 + RDCYCLETIME1.

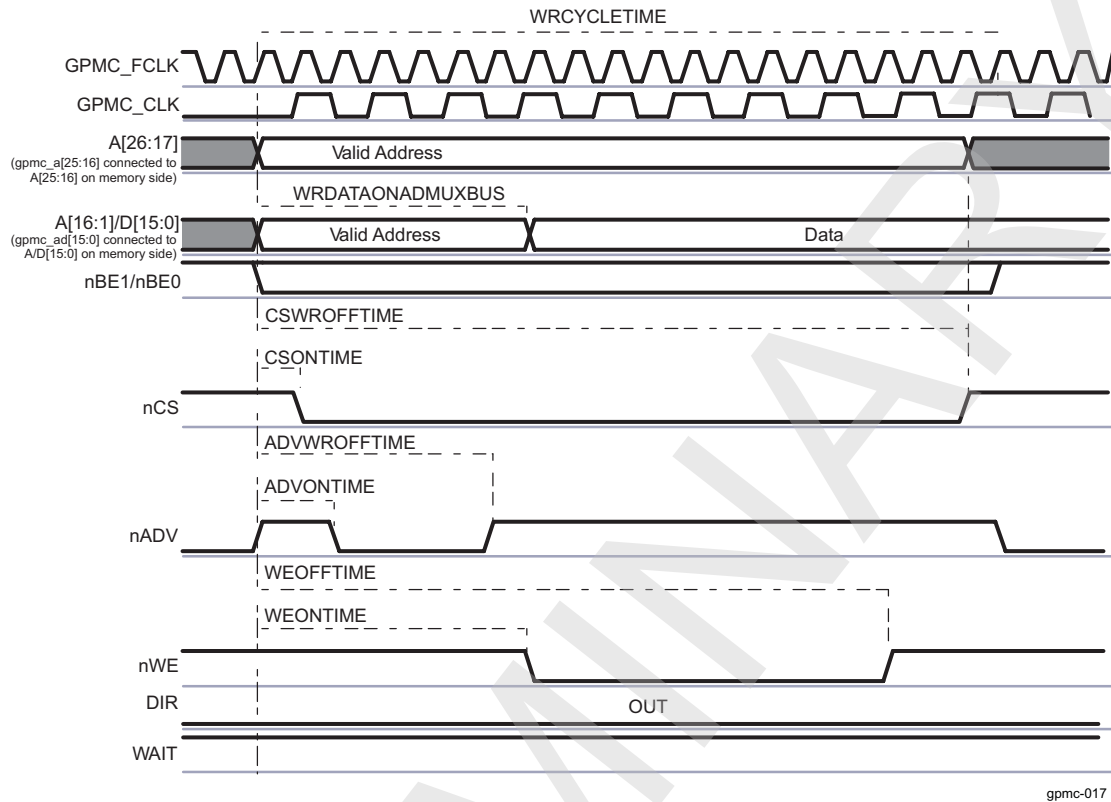

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 15.4.4.10.10, Bus Keeping Support](#).

Burst wraparound is enabled through the [GPMC\\_CONFIG1\\_i\[31\]](#) WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through [GPMC\\_CONFIG1\\_i\[24:23\]](#) ATTACHEDDEVICEPAGELENGTH.

### 15.4.4.11.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses.

**Figure 15-70. Synchronous Single Write on an Address/Data-Multiplexed Device**

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until GPMC\_CONFIG6\_i[19:16] WRDATAONADMUXBUS time. First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

#### 15.4.4.11.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses.

Figure 15-71 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

**Figure 15-71. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode**

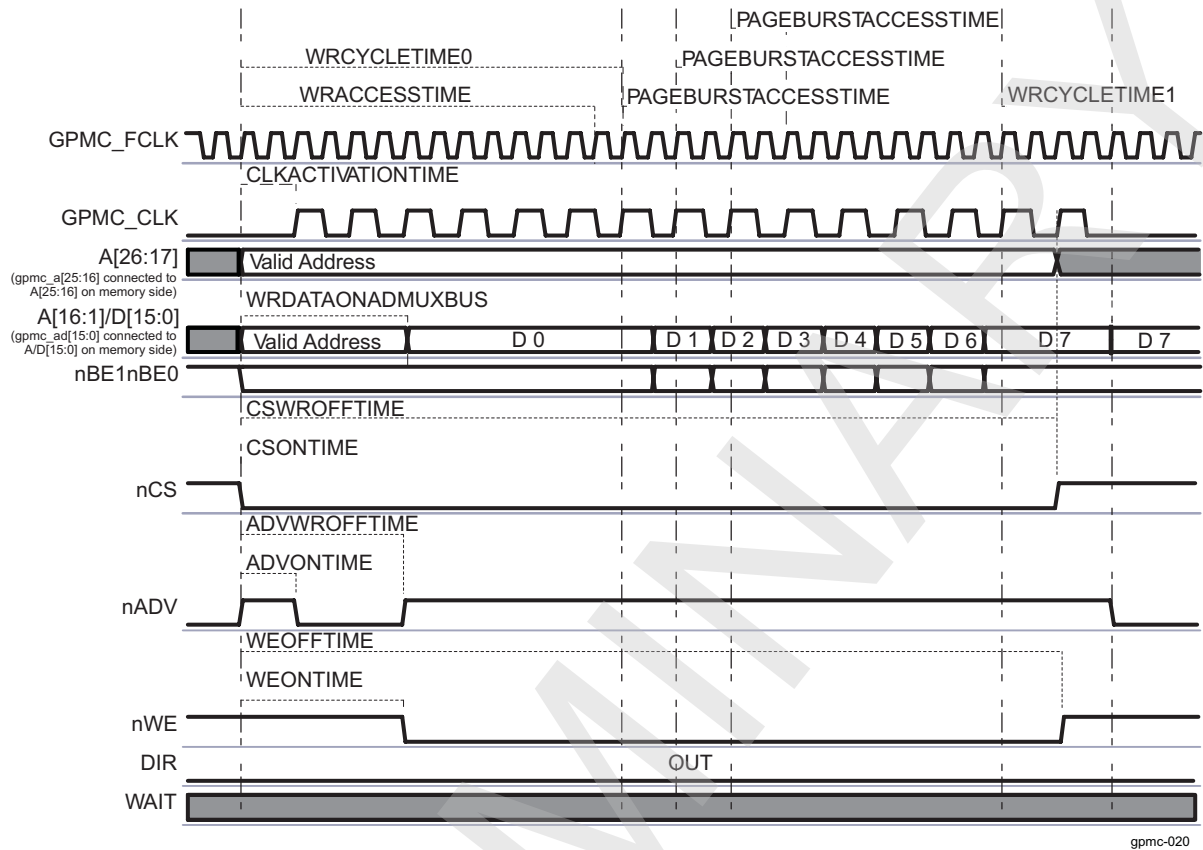

Figure 15-72 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

Figure 15-72. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode

The first data of the burst is driven on the A/D bus at `GPMC_CONFIG6_i[19:16]` WRDATAONADMUXBUS.

When WRACCESTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the `GPMC_CONFIG5_i[27:24]` PAGEBURSTACCESTIME multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see [Section 15.4.4.9.2.3, Address/Data-Multiplexing Interface](#).

- Chip-select signal nCS:
  - nCS assertion time is controlled by the `GPMC_CONFIG2_i[3:0]` CSONTIME field (i = 0 to 3) and ensures address setup time to nCS assertion.
  - nCS deassertion time controlled by the `GPMC_CONFIG2_i[20:16]` CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the `GPMC_CONFIG3_i[3:0]` ADVONTIME field.
  - nADV deassertion time is controlled by the `GPMC_CONFIG3_i[20:16]` ADVWROFFTIME field.
- Write enable signal nWE:
  - nWE assertion indicates a read cycle.
  - nWE assertion time is controlled by the `GPMC_CONFIG4_i[19:16]` WEONTIME field.

- nWE deassertion time is controlled by the [GPMC\\_CONFIG4\\_i\[28:24\]](#) WEOFFTIME field.

---

**NOTE:** The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus because some new devices require the nWE signal at low during the address phase.

---

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as detailed above.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the [GPMC\\_CONFIG3\\_i\[6:4\]](#) ADVAADMUXONTIME field.
  - nADV first deassertion time is controlled by the [GPMC\\_CONFIG3\\_i\[26:24\]](#) ADVAADMUXRDOFFTIME field.
  - nADV second assertion time is controlled by the [GPMC\\_CONFIG3\\_i\[3:0\]](#) ADVONTIME field.
  - nADV second deassertion time is controlled by the [GPMC\\_CONFIG3\\_i\[12:8\]](#) ADVRDOFFTIME field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the [GPMC\\_CONFIG4\\_i\[6:4\]](#) OEAADMUXONTIME field.
  - nOE first deassertion time is controlled by the [GPMC\\_CONFIG4\\_i\[15:13\]](#) OEAADMUXOFFTIME field.
  - nOE second assertion time is controlled by the [GPMC\\_CONFIG4\\_i\[3:0\]](#) OEONTIME field.
  - nOE second deassertion time is controlled by the [GPMC\\_CONFIG4\\_i\[12:8\]](#) OEOFFTIME field.

First write data is driven by the GPMC at [GPMC\\_CONFIG6\\_i\[19:16\]](#) WRDATAONADMUXBUS, when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during [GPMC\\_CONFIG5\\_i\[27:24\]](#) PAGEBURSTACCESSTIME GPMC\_FCLK cycles. The last data of the synchronous burst write is driven until [GPMC\\_CONFIG5\\_i\[12:8\]](#) WRCYCLETIME completes.

- WRACCESSTIME is defined in the [GPMC\\_CONFIG6\\_i\[28:24\]](#) register.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time [GPMC\\_CONFIG5\\_i\[12:8\]](#) WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In [Figure 15-71](#), the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See [Section 15.4.4.10.10, Bus Keeping Support](#).

#### 15.4.4.11.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

Page mode is only available in non-muxed mode. The non-muxed mode is described in this section even though its use is very limited (address space limited to 2 KBytes).

- Asynchronous single read operation on a nonmultiplexed device
- Asynchronous single write operation on a nonmultiplexed device
- Asynchronous multiple (page mode) read operation on a nonmultiplexed device
- Synchronous operations on a nonmultiplexed device

##### 15.4.4.11.3.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

[Figure 15-73](#) shows an asynchronous single read operation on a nonmultiplexed device.

**Figure 15-73. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device**

The 10-bit address is driven onto the address bus A[10:1] and the 16-bit data is driven onto the data bus D[15:0].

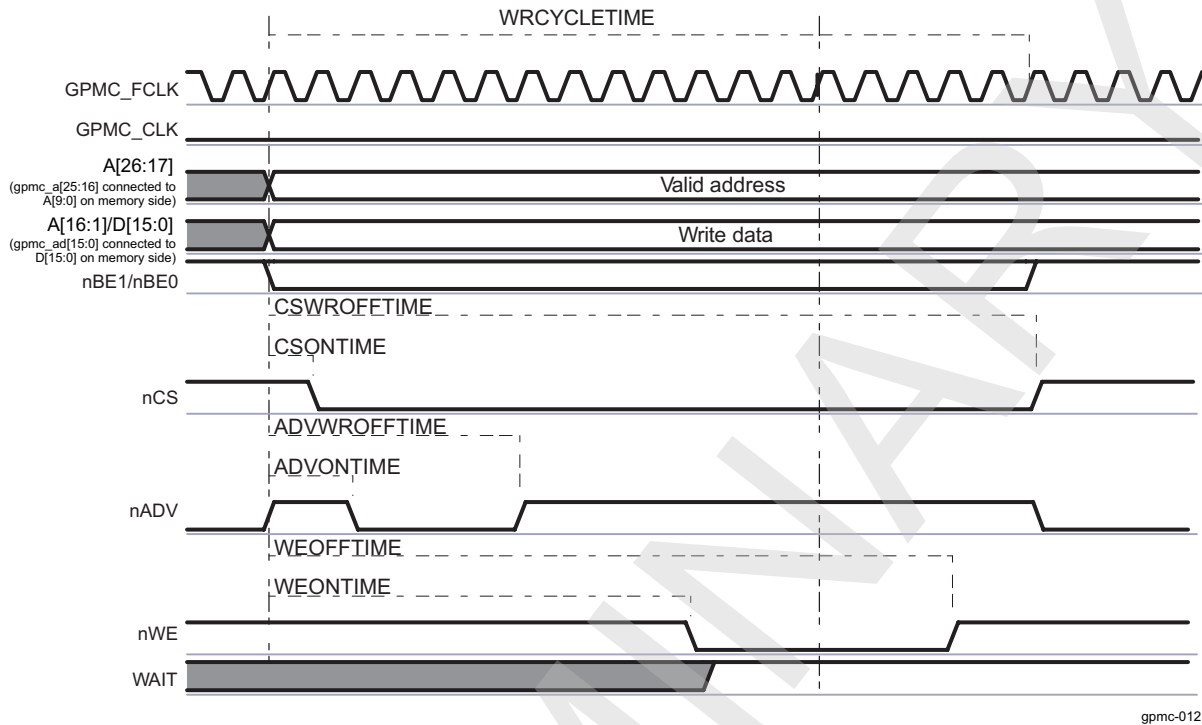

Read data is latched at [GPMC\\_CONFIG1\\_5\[20:16\]](#) RDACCESSTIME completion time. The end of the access is defined by the [GPMC\\_CONFIG1\\_5\[4:0\]](#) RDCYCLETIME parameter.

Set [GPMC\\_CONFIG\[1\] LIMITEDADDRESS](#) to 0x1 (A26-A11 are not modified during an external memory access).

nCS, nADV, nOE and DIR signals are controlled in the same way as address/data multiplexed accesses, see [Table 15-247](#).

#### 15.4.4.11.3.2 Asynchronous Single Write Operation on a Nonmultiplexed Device

[Figure 15-74](#) shows an asynchronous single write operation on a nonmultiplexed device.

**Figure 15-74. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device**

The 10-bit address is driven onto the address bus A[10:1] and the 16-bit data is driven onto the data bus D[15:0].

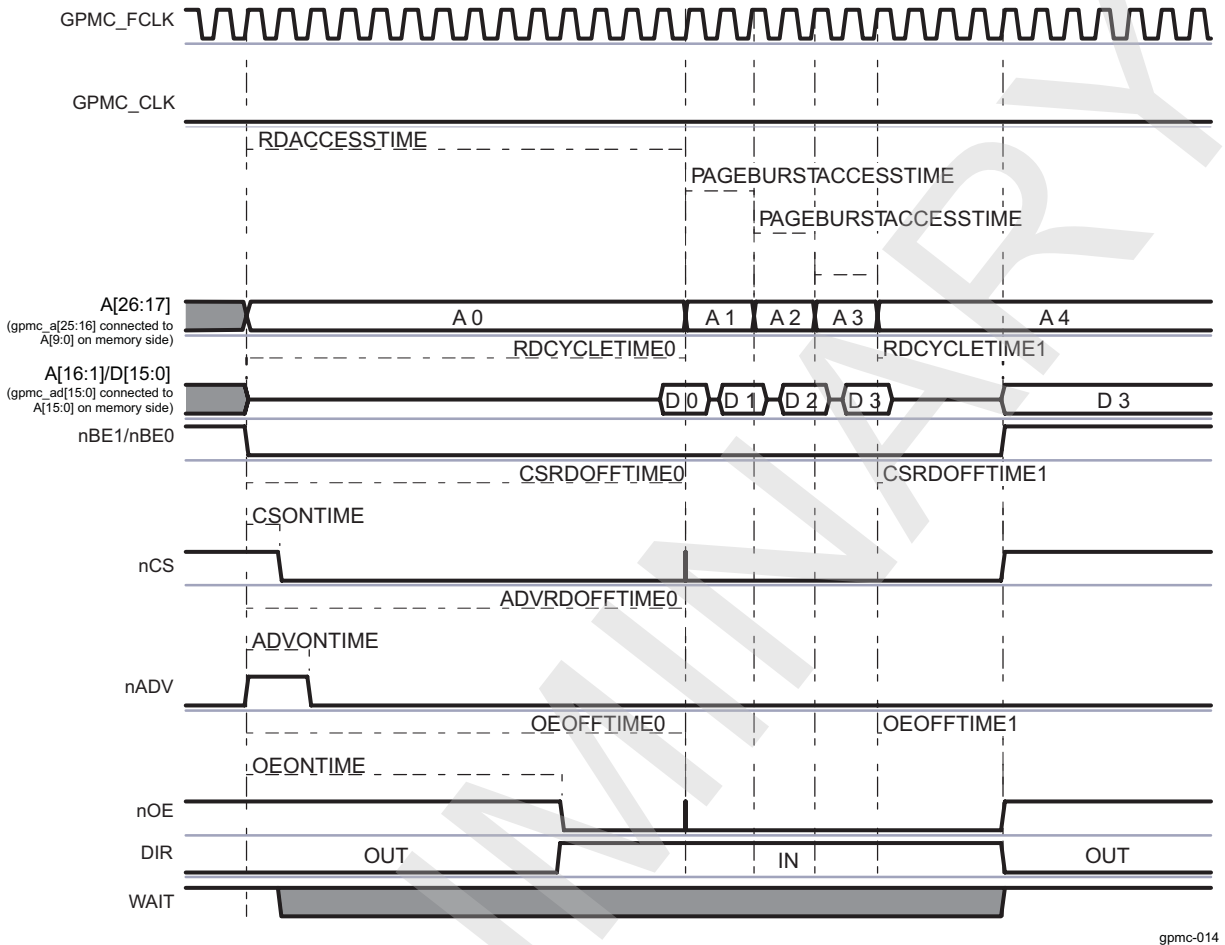

Set `GPMC_CONFIG[1] LIMITEDADDRESS` to 0x1 (A26-A11 are not modified during an external memory access).

nCS, nADV, nWE and DIR signals are controlled in the same way as address/data multiplexed accesses, see [Table 15-247](#).

#### 15.4.4.11.3.3 Asynchronous Multiple (Page Mode) Read Operation on a Nonmultiplexed Device

[Figure 15-75](#) shows an asynchronous multiple read operation on a Nonmultiplexed Device, in which two word32 host read accesses to the GPMC are split into one multiple (page mode of 4 word16) read access to the attached device.

Figure 15-75. Asynchronous Multiple (Page Mode) Read

**NOTE:** The WAIT signal is active low.

nCS, nADV, nOE and DIR signals are controlled in the same way as address/data multiplexed accesses, see [Table 15-247](#).

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at [GPMC\\_CONFIG5\\_i\[20:16\]](#) RDACCESSTIME completion time (i = 0 to 3). The end of the access is defined by the [GPMC\\_CONFIG5\\_i\[4:0\]](#) RDCYCLETIME parameter.

Set [GPMC\\_CONFIG\[1\]](#) LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the [GPMC\\_CONFIG5\\_i\[27:24\]](#) PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time starting from the nCS deassertion.

- The read cycle time is defined in the [GPMC\\_CONFIG5\\_i\[4:0\]](#) RDCYCLETIME field.
- In [Figure 15-75](#), the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

#### 15.4.4.11.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data- or AAD-multiplexed accesses. The only difference resides in the address phase. See [Section 15.4.5.3, GPMC Configuration in NOR Mode](#).

#### 15.4.4.11.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The [GPMC\\_CONFIG1\\_i\[30\]](#) READMULTIPLE and [GPMC\\_CONFIG1\\_i\[28\]](#) WRITMULTIPLE bits ( $i = 0$  to 3) are associated with the READTYPE and WRITETYPE parameters.

---

**NOTE:**

- Asynchronous write page mode is not supported.
  - 8-bit wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
  - Not applicable to NAND device interfacing.
- 

#### 15.4.4.11.5 System Burst Versus External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the [GPMC\\_CONFIG1\\_i\[24:23\]](#) ATTACHEDDEVICEPAGELENGTH field ( $i = 0$  to 3). When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the [GPMC\\_CONFIG1\\_i\[31\]](#) WRAPBURST bit ( $i = 0$  to 3) must be set to 1. Similarly DEVICESPAGELENGTH is set to 4 and 8 for memories supporting respectively 4 and 8 Word16-length-wrapping burst.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the `GPMC_CONFIG1_i[24:23]` `ATTACHEDDEVICEPAGELENGTH` field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the `ATTACHEDDEVICEPAGELENGTH` value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst.

---

**NOTE:** When the system burst request length is less than the `ATTACHEDDEVICEPAGELENGTH` value, the GPMC proceeds with the required accesses.

---

#### 15.4.4.12 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The `GPMC_CONFIG1_i[11:10]` `DEVICETYPE` field ( $i = 0$  to 3) shall be set to 0b00.

The pSRAM devices uses the NOR protocol. It support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR Flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its `WAIT` signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional `WAIT` signal capability or a minimum `nCS` high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

#### 15.4.4.13 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices.

This interleaved capability limits the system to *chip enable don't care* NAND devices since the chip-select allocated to the NAND device has to be de-asserted if accesses to other chip-selects are requested.

##### 15.4.4.13.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or 16-bit word).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

#### 15.4.4.13.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The [GPMC\\_CONFIG7\\_i](#) register (where  $i = 0$  to 3) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

#### CAUTION

To allow correct command, address, and data-access controls, the [GPMC\\_CONFIG1\\_i](#) register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters shown in [Table 15-223](#). Failure to comply with these settings corrupts the NAND interface protocol.

**Table 15-223. Chip-Select Configuration for NAND Interfacing**

Bit Field	Register	Value	Comments
WRAPBURST	<a href="#">GPMC_CONFIG1_i[31]</a> <sup>(1)</sup>	0	No wrap
READMULTIPLE	<a href="#">GPMC_CONFIG1_i[30]</a>	0	Single access
READTYPE	<a href="#">GPMC_CONFIG1_i[29]</a>	0	Asynchronous mode
WRITEMULTIPLE	<a href="#">GPMC_CONFIG1_i[28]</a>	0	Single access
WRITETYPE	<a href="#">GPMC_CONFIG1_i[27]</a>	0	Asynchronous mode
CLKACTIVATIONTIME	<a href="#">GPMC_CONFIG1_i[26:25]</a>	0b00	
ATTACHEDDEVICEPAGELENGTH	<a href="#">GPMC_CONFIG1_i[24:23]</a>	Don't care	Single-access mode
WAITREADMONITORING	<a href="#">GPMC_CONFIG1_i[22]</a>	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	<a href="#">GPMC_CONFIG1_i[21]</a>	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	<a href="#">GPMC_CONFIG1_i[19:18]</a>	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	<a href="#">GPMC_CONFIG1_i[17:16]</a>		Select which wait is monitored by edge detectors
DEVICESIZE	<a href="#">GPMC_CONFIG1_i[13:12]</a>	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	<a href="#">GPMC_CONFIG1_i[11:10]</a>	0b10	NAND device in stream mode
MUXADDDATA	<a href="#">GPMC_CONFIG1_i[9:8]</a>	0b00	Nonmultiplexed mode

<sup>(1)</sup>  $i = 0$  to 3

**Table 15-223. Chip-Select Configuration for NAND Interfacing (continued)**

Bit Field	Register	Value	Comments
TIMEPARAGRANULARITY	<a href="#">GPMC_CONFIG1_i[4]</a>	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	<a href="#">GPMC_CONFIG1_i[1:0]</a>	Don't care	Asynchronous mode

The [GPMC\\_CONFIG1\\_i](#) to [GPMC\\_CONFIG4\\_i](#) register (where  $i = 0$  to  $3$ ) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

#### 15.4.4.13.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The MPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the [GPMC\\_NAND\\_COMMAND\\_i](#) and [GPMC\\_NAND\\_ADDRESS\\_i](#) register locations ( $i = 0$  to  $3$ ) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the [GPMC\\_NAND\\_COMMAND\\_i](#) register location and to the [GPMC\\_NAND\\_ADDRESS\\_i](#) register location must be posted for faster operations ( $i = 0$  to  $3$ ). The [GPMC\\_CONFIG\[0\]](#) NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An [GPMC\\_STATUS\[0\]](#) EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

[GPMC\\_NAND\\_COMMAND\\_i](#) and [GPMC\\_NAND\\_ADDRESS\\_i](#) ( $i = 0$  to  $3$ ) are 32-bit word locations, which means any 32-bit word or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32-bit word or 16-bit word access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to [GPMC\\_NAND\\_COMMAND\\_i](#) and [GPMC\\_NAND\\_ADDRESS\\_i](#) can be used, and any of the four byte locations of the registers are valid.

The same applies to a [GPMC\\_NAND\\_COMMAND\\_i](#) and a [GPMC\\_NAND\\_ADDRESS\\_i](#) ( $i = 0$  to  $3$ ) 32-bit word write access to a 16-bit wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

#### 15.4.4.13.1.3 Command Latch Cycle

Writing data at the [GPMC\\_NAND\\_COMMAND\\_i](#) location ( $i = 0$  to  $3$ ) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.

- ALE and nRE (nOE) are maintained inactive.

Figure 15-76 shows the NAND command latch cycle.

**Figure 15-76. NAND Command Latch Cycle**

**NOTE:** CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND Flash memories do not use byte enable signals at all.

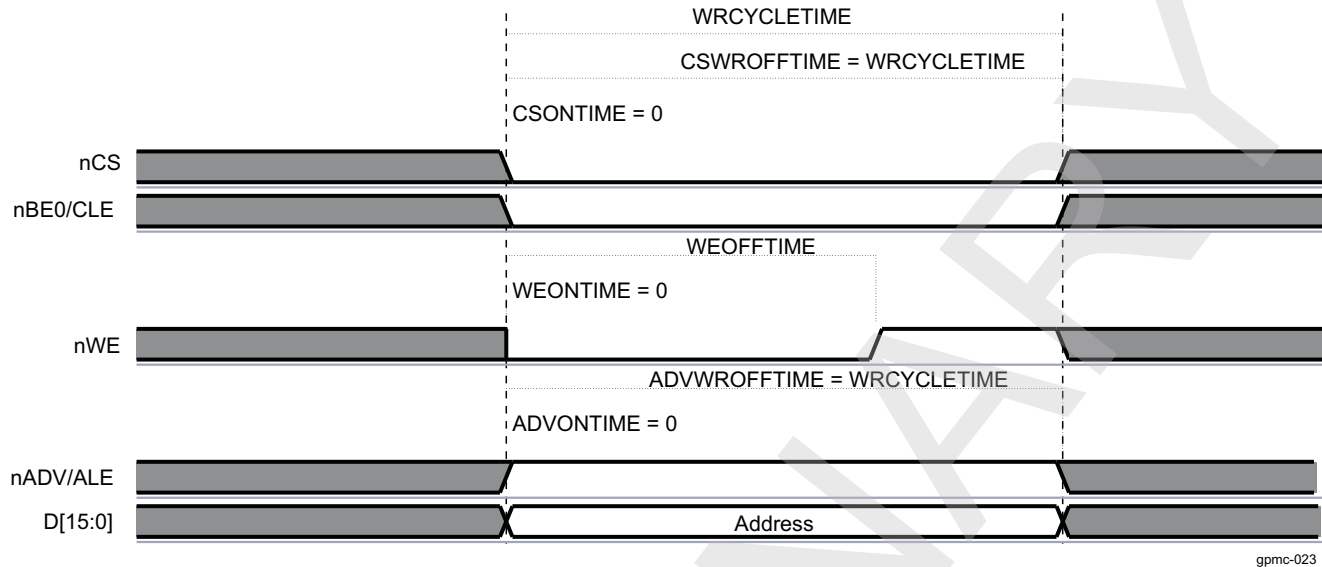

#### 15.4.4.13.1.4 Address Latch Cycle

Writing data at the [GPMC\\_NAND\\_ADDRESS\\_i](#) location ( $i = 0$  to 3) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 15-77 shows the NAND address latch cycle.

Figure 15-77. NAND Address Latch Cycle

**NOTE:** ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

#### 15.4.4.13.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the `GPMC_NAND_DATA_i` location ( $i = 0$  to 3) mapped in the chip-select-associated control register region. `GPMC_NAND_DATA_i` is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the `GPMC_NAND_DATA_i` location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device IC timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 15-78 shows the NAND data read cycle.

**Figure 15-78. NAND Data Read Cycle**

Writing data to the `GPMC_NAND_DATA_i` location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 15-79 shows the NAND data write cycle.

**Figure 15-79. NAND Data Write Cycle**

#### 15.4.4.13.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce

RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, and WEOFFTIME on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses. For more information about optimal prefetch engine access, see [Section 15.4.4.13.4, Prefetch and Write-Posting Engine](#).

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMEECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high to data bus in tristate mode. This requires a bus turnaround setting (BUSTURNAROUND = 1), so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND Flash are not affected by the programmed bus turnaround delay.

### **15.4.4.13.1.7 Read and Write Access Size Adaptation**

#### **15.4.4.13.1.7.1 8-bit wide NAND Device**

Host 16-bit word and 32-bit word read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

#### **15.4.4.13.1.7.2 16-bit wide NAND Device**

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

### **15.4.4.13.2 NAND Device-Ready Pin**

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

**NOTE:** If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the [GPMC\\_CONFIG1\\_i\[21\]](#) WAITWRITEMONITORING and [GPMC\\_CONFIG1\\_i\[22\]](#) WAITREADMONITORING bits to 0, where  $i = 0$  to 3), and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit ( $n = 0$  to 3) of the [GPMC\\_STATUS](#) register.
- Configure an interrupt that is generated on the WAIT signal change (through the [GPMC\\_IRQENABLE](#) register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the [GPMC\\_STATUS](#) register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

#### 15.4.4.13.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the [GPMC\\_STATUS](#) WAITxSTATUS bit ( $x = 0$  or 1). The software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

#### 15.4.4.13.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc\_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the [GPMC\\_CONFIG](#) WAITxPINPOLARITY bits ( $x = 0$  or 1) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit ( $x = 0$  or 3) of the [GPMC\\_IRQSTATUS](#) register according to the gpmc\_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC\_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the [GPMC\\_IRQENABLE](#) register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the [GPMC\\_IRQSTATUS](#) register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the [GPMC\\_IRQSTATUS](#) register according to the gpmc\_wait pin used for the NAND device ready signal monitoring.

#### 15.4.4.13.3 ECC Calculator

The General Purpose Memory Controller includes an Error Code Correction (ECC) calculator circuitry that enables on the fly ECC calculation during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the [GPMC\\_ECC\\_CONFIG\[16\]](#) ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND Flash organized with page size greater than 512 bytes
2. BCH (Bose-Chaudhuri-Hocquenghem) code for 4- to 16-bit error correction

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or 16-bit words read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the [GPMC\\_ECC\\_CONFIG\[3:1\]](#) ECCCS bit field. Even if two CS use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

#### **15.4.4.13.3.1 Hamming Code**

All references to Error Code Correction (ECC) in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming Code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

##### **15.4.4.13.3.1.1 ECC Result Register and ECC Computation Accumulation Size**

The GPMC includes up to nine ECC result registers ([GPMC\\_ECCj\\_RESULT](#),  $j = 1$  to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The [GPMC\\_ECCj\\_RESULT](#) register value is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The [GPMC\\_ECC\\_CONTROL\[3:0\]](#) ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The [GPMC\\_ECCj\\_RESULT](#) register value ( $j = 1$  to 9) can be considered valid when ECCPOINTER equals  $j + 1$ . When [GPMC\\_ECCj\\_RESULT](#) (where  $j = 9$ ) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The [GPMC\\_ECC\\_CONTROL\[8\]](#) ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each [GPMC\\_ECCj\\_RESULT](#) register,  $j = 1$  to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSISE bits (j = 1 to 9) in the [GPMC\\_ECC\\_SIZE\\_CONFIG](#) register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in [GPMC\\_ECCj\\_RESULT](#)).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2 Kbyte data page 8-bit wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine [GPMC\\_ECCj\\_RESULT](#) registers (j= 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8]RESULTSISE bits are set to 0, and the ECC9RESULTSISE bit is set to 1.

#### 15.4.4.13.3.1.2 ECC Enabling

The [GPMC\\_ECC\\_CONFIG](#)[3:1] ECCCS field selects the allocated chip-select. The [GPMC\\_ECC\\_CONFIG](#)[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSISE (where j = 1 to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

[Table 15-224](#) describes the ECC enable settings.

**Table 15-224. ECC Enable Settings**

Bit Field	Register	Value	Comments
ECCCS	<a href="#">GPMC_ECC_CONFIG</a>	0-3	Selects the chip-select where ECC is computed
ECC16B	<a href="#">GPMC_ECC_CONFIG</a>	0/1	Selects column number for ECC calculation
ECCCLEAR	<a href="#">GPMC_ECC_CONTROL</a>	0-7	Clears all ECC result registers
ECCPOINTER	<a href="#">GPMC_ECC_CONTROL</a>	0-7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	<a href="#">GPMC_ECC_SIZE_CONFIG</a>	0x00-0xFF	Defines ECCSIZE1
ECCSIZE0	<a href="#">GPMC_ECC_SIZE_CONFIG</a>	0x00-0xFF	Defines ECCSIZE0
ECCjRESULTSISE (j from 1 to 9)	<a href="#">GPMC_ECC_SIZE_CONFIG</a>	0/1	Selects the size of ECCn result register
ECCENABLE	<a href="#">GPMC_ECC_CONFIG</a>	1	Enables the ECC computation

#### 15.4.4.13.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in [Figure 15-80](#) and [Figure 15-81](#). The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

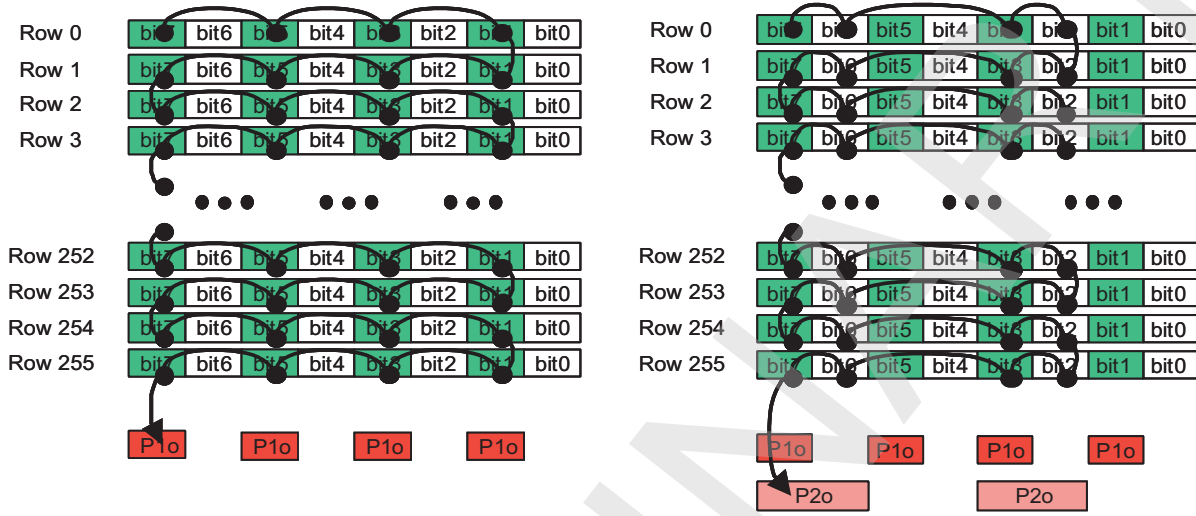

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream  
 P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream  
 Each column parity bit is XORed with the previous accumulated value.

Figure 15-80. Hamming Code Accumulation Algorithm (1/2)

gpmc-026

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

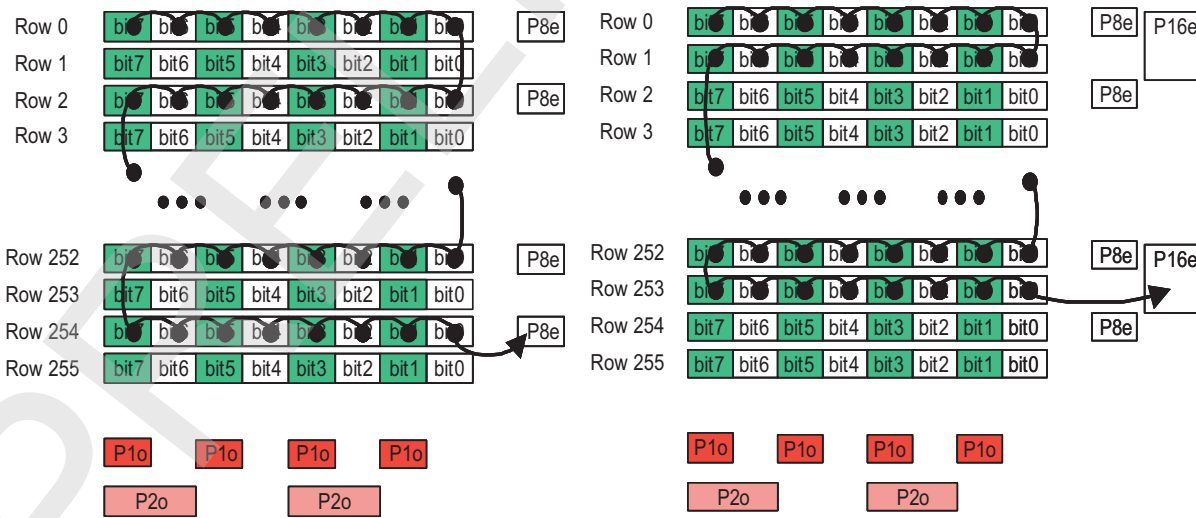

$$P8e = \text{row0 XOR row2 XOR row4 XOR ... XOR row254}$$

$$P8o = \text{row1 XOR row3 XOR row5 XOR ... XOR row255}$$

$$P16e = \text{row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253}$$

$$P16o = \text{row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255}$$

Figure 15-81. Hamming Code Accumulation Algorithm (2/2)

gpmc-027

Unused parity bits in the result registers are set to 0.

Figure 15-82 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 15-82. ECC Computation for a 256-Byte Data Stream (Read or Write)

gpmc-028

Figure 15-83 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

Figure 15-83. ECC Computation for a 512-Byte Data Stream (Read or Write)

gpmc-029

For a 2 Kbytes page, four 512 bytes ECC calculations plus one for the spare area are required. Results are stored in the [GPMC\\_ECCj\\_RESULT](#) registers (j = 1 to 9).

**15.4.4.13.3.1.4 ECC Comparison and Correction**

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

**15.4.4.13.3.1.5 ECC Calculation Based on 8-Bit Word**

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

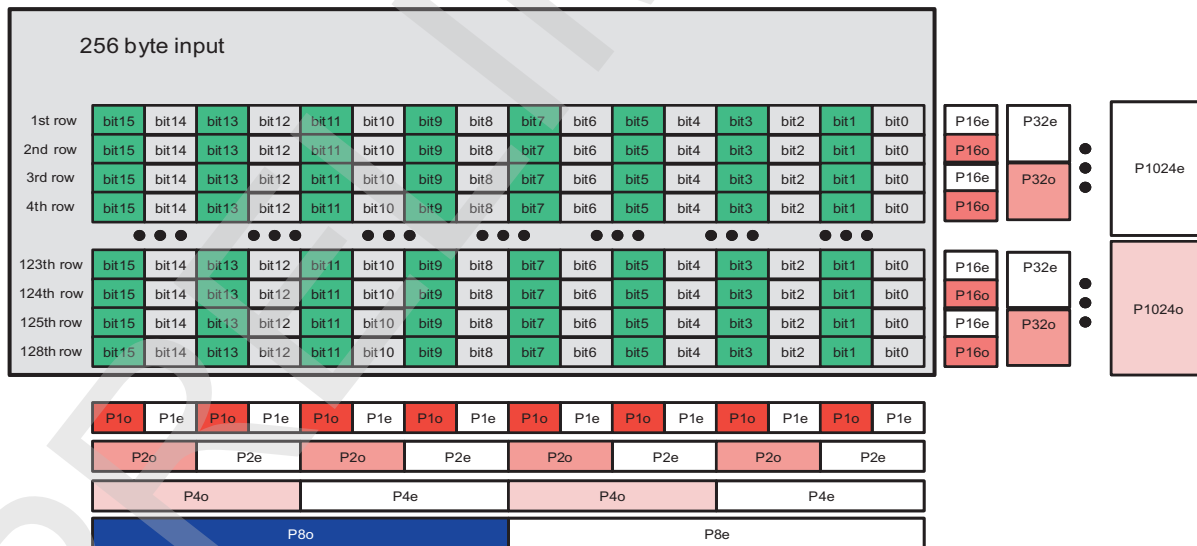

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

**15.4.4.13.3.1.6 ECC Calculation Based on 16-Bit Word**

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the [GPMC\\_ECC\\_CONFIG\[7\]](#) ECC16B bit must be set to 0 when interfacing an 8-bit wide NAND device.

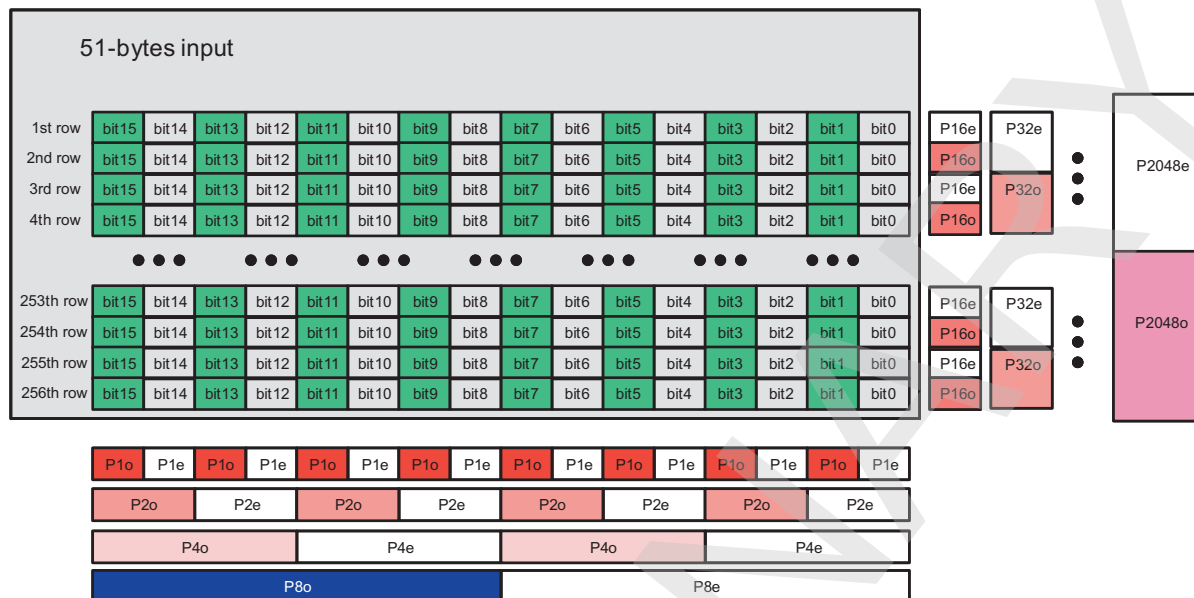

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. [Figure 15-84](#) and [Figure 15-85](#) show a 128 Word 16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

**Figure 15-84. 128 Word16 ECC Computation**

gpmc-030

Figure 15-85. 256 Word16 ECC Computation

gpmc-031

#### 15.4.4.13.3.2 BCH Code (Bose-Chaudhuri-Hocquenghem)

All references to Error Code Correction (ECC) in this subsection refer to the 4- to 16-bit error correction BCH code.

##### 15.4.4.13.3.2.1 Requirements

- Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses. Typical page write sequence:
  - Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.
  - When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
  - NAND writes its cache line (page) to the array.
 Typical page read sequence:
  - Sequential read of a page. ECC is calculated on the fly.
  - ECC module buffers status determines the presence of errors.
- Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
- Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to 8 x 512-byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time. The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
- NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4 cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a

RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.

- The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

**15.4.4.13.3.2.2 Memory-Mapping of the BCH Codeword**

BCH encoding considers a block of data to protect as a polynomial message  $M(x)$ . In our standard case, 512 bytes of data (that is,  $2^{12}$  bits = 4096 bits) are seen as a polynomial of degree  $2^{12} - 1 = 4095$ , with parameters ranging from  $M_0$  to  $M_{4095}$ . For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial  $R(x)$  of degree 103 (or 51, depending on the selected mode). The complete codeword  $C(x)$  is the concatenation of  $M(x)$  and  $R(x)$  as shown in Table 15-225.

**Table 15-225. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)**

	Message $M(x)$			ECC $R(x)$		
Bit number	$M_{4095}$	...	$M_0$	$R_{103}$	...	$R_0$

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message  $M(x)$  of degree  $((512 + 3) * 8) - 1 = 4119$ , for a total of  $3+13 = 16$  spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in `GPMC_BCH_RESULT0_i`, `GPMC_BCH_RESULT1_i`, `GPMC_BCH_RESULT2_i`, and `GPMC_BCH_RESULT3_i` (where  $i = 0$  to 3).

**15.4.4.13.3.2.2.1 Memory-Mapping of the Data Message**

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte  $b_7$ - $b_0$  (with  $b_0$  the LS bit) represents a segment of polynomial  $b_7 * x^{(7+i)} + b_6 * x^{(6+i)} + \dots + b_0 * x^i$
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

**NOTE:** The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, and this produces the mapping patterns described below.

The following tables represent the mapping of the same 512-byte vector (typically a BCH message) in the NANDs memory space. Note that the byte 'address' is only an offset modulo 512 (0x200), since the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits  $M_0$  and  $M(2^{12}-1)$  of the codeword mapping given above. In both cases the data vectors are aligned, that is, their boundaries coincide with the RAMs data word boundaries.

**Table 15-226. Aligned Message Byte Mapping in 8-bit NAND**

Byte offset	8-bit word
0x000	(msb) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...

**Table 15-226. Aligned Message Byte Mapping in 8-bit NAND (continued)**

Byte offset	8-bit word
0x1FF	Byte 0 (0x0) (lsb)

**Table 15-227. Aligned Message Byte Mapping in 16-bit NAND**

Byte offset	16-bit words MSB	16-bit words LSB
0x000	Byte 510 (0x1FE)	(msb) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...	...	...
0x1FE	Byte 0 (0x0)	(lsb) Byte 1 (0x1)

The following tables show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on another sectors ECC).

**Table 15-228. Aligned Nibble Mapping of Message in 8-bit NAND**

Byte offset	8-bit word	
	4-bit most significant Nibble	4-bit less significant Nibble
1	(msb) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
S/2 - 2	Nibble 3	Nibble 2
S/2 - 1	Nibble 1	Nibble 0 (lsb)

**Table 15-229. Misaligned Nibble Mapping of Message in 8-bit NAND**

Byte offset	8-bit word	
	4-bit most significant Nibble	4-bit less significant Nibble
1	(msb) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
(S+1)/2 - 2	Nibble 2	Nibble 1
(S+1)/2 - 1	Nibble 0 (lsb)	

**Table 15-230. Aligned Nibble Mapping of Message in 16-bit NAND**

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
S/2 - 4	Nibble 5	Nibble 4	Nibble 7	Nibble 6
S/2 - 2	Nibble 1	Nibble 0 (lsb)	Nibble 3	Nibble 2

**Table 15-231. Misaligned Nibble Mapping of Message in 16-bit NAND (1 Unused Nibble)**

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
(S+1)/2 - 4	Nibble 4	Nibble 3	Nibble 6	Nibble 5
(S+1)/2 - 2	Nibble 0 (lsb)		Nibble 2	Nibble 1

**Table 15-232. Misaligned Nibble Mapping of Message in 16-bit NAND (2 Unused Nibbles)**

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
(S+2)/2 - 4	Nibble 3	Nibble 2	Nibble 5	Nibble 4
(S+2)/2 - 2			Nibble 1	Nibble 0 (lsb)

**Table 15-233. Misaligned Nibble Mapping of Message in 16-bit NAND (3 Unused Nibbles)**

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
(S+3)/2 - 4	Nibble 2	Nibble 1	Nibble 4	Nibble 3
(S+3)/2 - 2			Nibble 0 (lsb)	

Note that many other cases exist than the ones represented above, for example, where the message does not start on a word boundary.

#### 15.4.4.13.3.2.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 bytes) from the modules interface, then store them to the NANDs spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is a softwarecontrolled operation.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error as been detected. The creation of this codeword should be made as straightforward as possible.

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

#### 15.4.4.13.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see [Section 15.4.4.13.3.2.3, Supported NAND Page Mappings and ECC Schemes](#).

For each mode:

- a sequence describes the mode in pseudo-language, with for each section the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0 and size1.
- a checksum condition is given. If the checksum condition is not respected for a given mode, the modules behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Note that wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for  $t = 4$  ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

#### 15.4.4.13.3.2.2.4 Manual Mode (0x0)

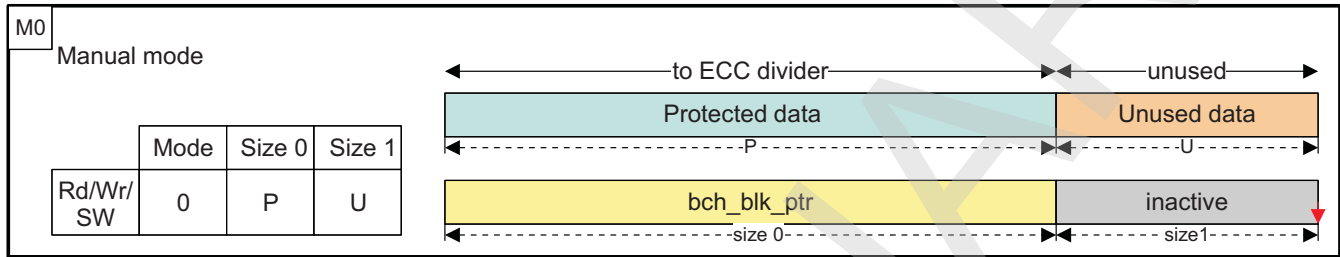

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port shall be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles shall be programmed in size1 (in the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 x 16-bit accesses: we must program size0 = 5, size1 = 3).

**NOTE:** In the following figures size and size0 are the same parameter.

**Figure 15-86. Manual Mode Sequence and Mapping**

gpmc-032

Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

**15.4.4.13.3.2.2.5 Mode 0x1**

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

**15.4.4.13.3.2.2.6 Mode 0xA (10)**

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

**15.4.4.13.3.2.2.7 Mode 0x2**

Page processing sequence:

- Repeat with buffer 0 to S-1

- 512-byte data, processing ON
  - Repeat with buffer 0 to S-1
    - size0 nibbles spare, processing OFF
    - size1 nibbles spare, processing ON
- Checksum: Spare area size (nibbles) = S - (size0 + size1)

#### 15.4.4.13.3.2.2.8 Mode 0x3

- Page processing sequence:
- Repeat with buffer 0 to S-1
    - 512-byte data, processing ON
  - One time with buffer 0
    - size0 nibbles spare, processing ON
  - Repeat with buffer 0 to S-1
    - size1 nibbles spare, processing ON
- Checksum: Spare area size (nibbles) = size0 + (S - size1)

#### 15.4.4.13.3.2.2.9 Mode 0x7

- Page processing sequence:
- Repeat with buffer 0 to S-1
    - 512-byte data, processing ON
  - One time with buffer 0
    - size0 nibbles spare, processing ON
  - Repeat S times (no buffer used)
    - size1 nibbles spare, processing OFF
- Checksum: Spare area size (nibbles) = size0 + (S - size1)

#### 15.4.4.13.3.2.2.10 Mode 0x8

- Page processing sequence:
- Repeat with buffer 0 to S-1
    - 512-byte data, processing ON
  - One time with buffer 0
    - size0 nibbles spare, processing ON
  - Repeat with buffer 0 to S-1
    - 1 nibble padding spare, processing OFF
    - size1 nibbles spare, processing ON
- Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

#### 15.4.4.13.3.2.2.11 Mode 0x4

- Page processing sequence:
- Repeat with buffer 0 to S-1
    - 512-byte data, processing ON
  - One time (no buffer used)
    - size0 nibbles spare, processing OFF
  - Repeat with buffer 0 to S-1
    - size1 nibbles spare, processing ON
- Checksum: Spare area size (nibbles) = size0 + (S - size1)

**15.4.4.13.3.2.2.12 Mode 0x9**

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

**15.4.4.13.3.2.2.13 Mode 0x5**

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

**15.4.4.13.3.2.2.14 Mode 0xB (11)**

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

**15.4.4.13.3.2.2.15 Mode 0x6**

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

**15.4.4.13.3.2.3 Supported NAND Page Mappings and ECC Schemes**

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.

- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in [Section 15.4.4.13.3.2.1](#), *Memory-Mapping of the Data Message*.

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In [Figure 15-87](#) to [Figure 15-89](#), tables on the left summarize the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where :

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares, that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of  $n = 2^{13} - 1 = 8191$  bits. That codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, on the programmed sizes and on the sector number (all sizes in nibbles):

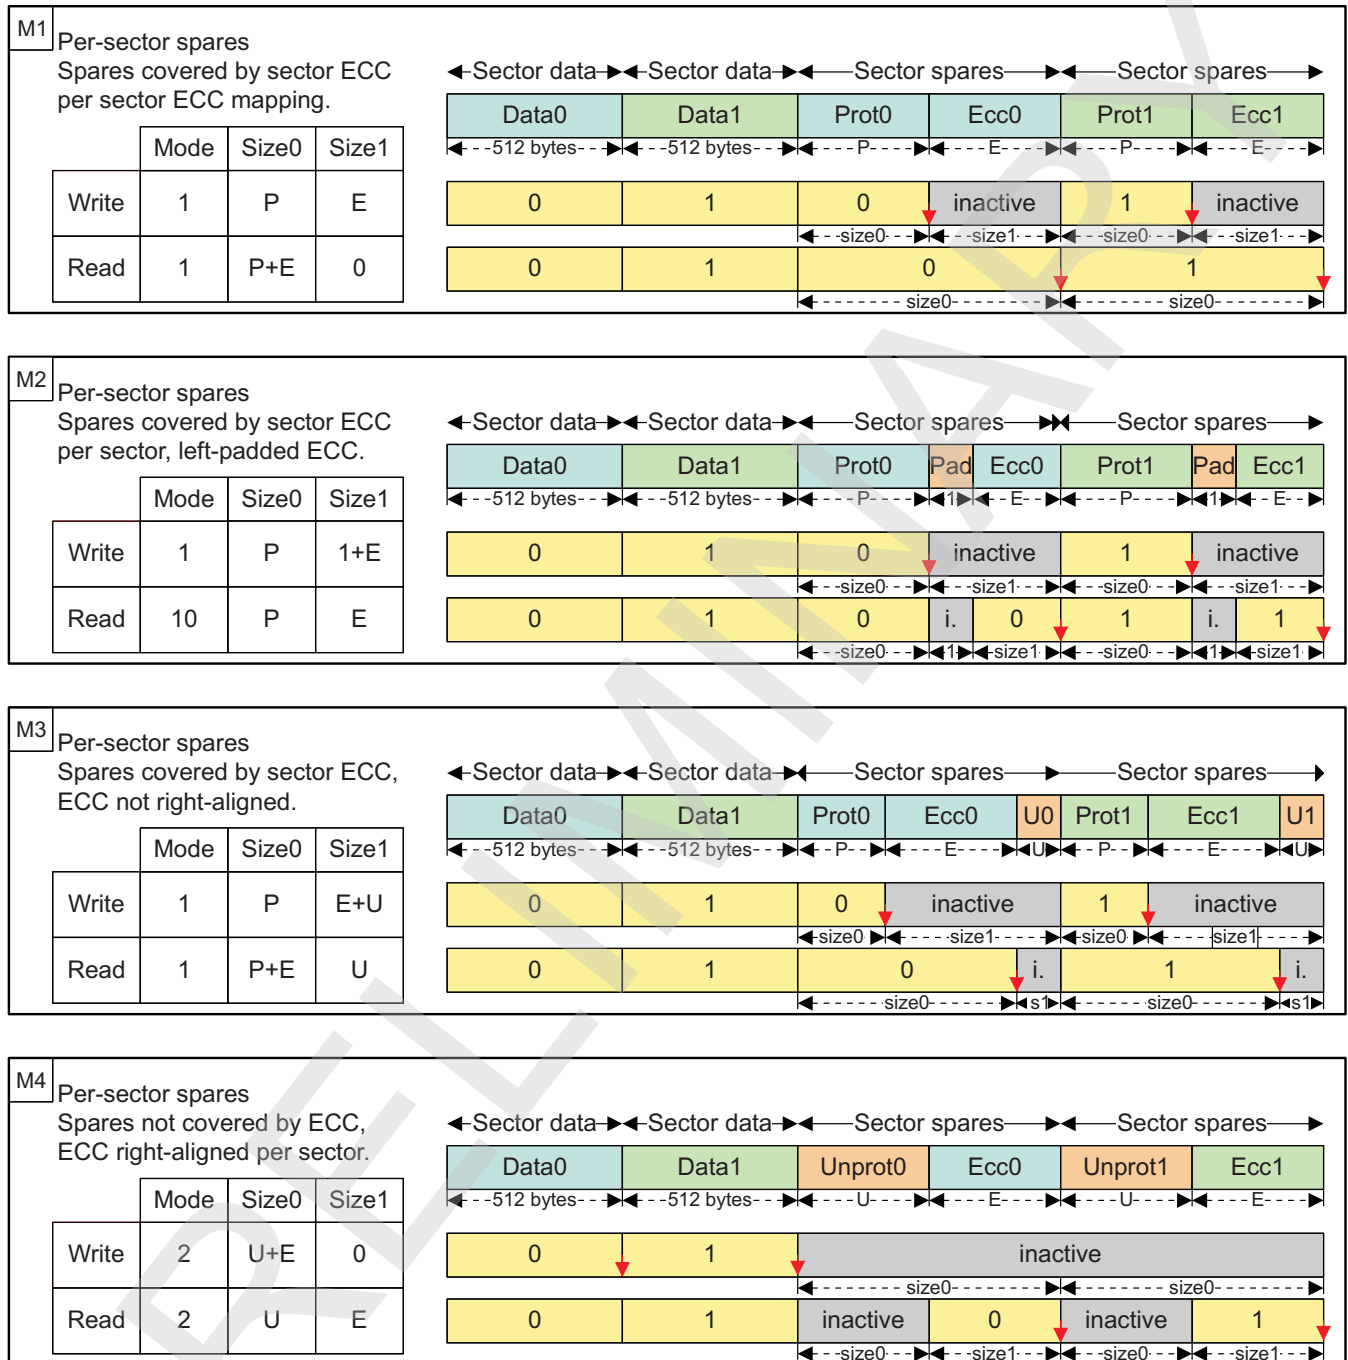

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
  - all sectors: (512) + P + E
- Spares pooled and protected by sector 0 (below: see M5-M6):
  - sector 0 codeword: (512) + P + E
  - other sectors: (512) + E
- Unprotected spares (below: see M4-M7-M8-M11-M12):
  - all codewords (512) + E

#### 15.4.4.13.3.2.3.1 *Per-Sector Spare Mappings*

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of :

- ECC, which must be located after the data it protects
- other data, which may or may not be protected by the sectors ECC

Figure 15-87. NAND Page Mapping and ECC: Per-Sector Schemes

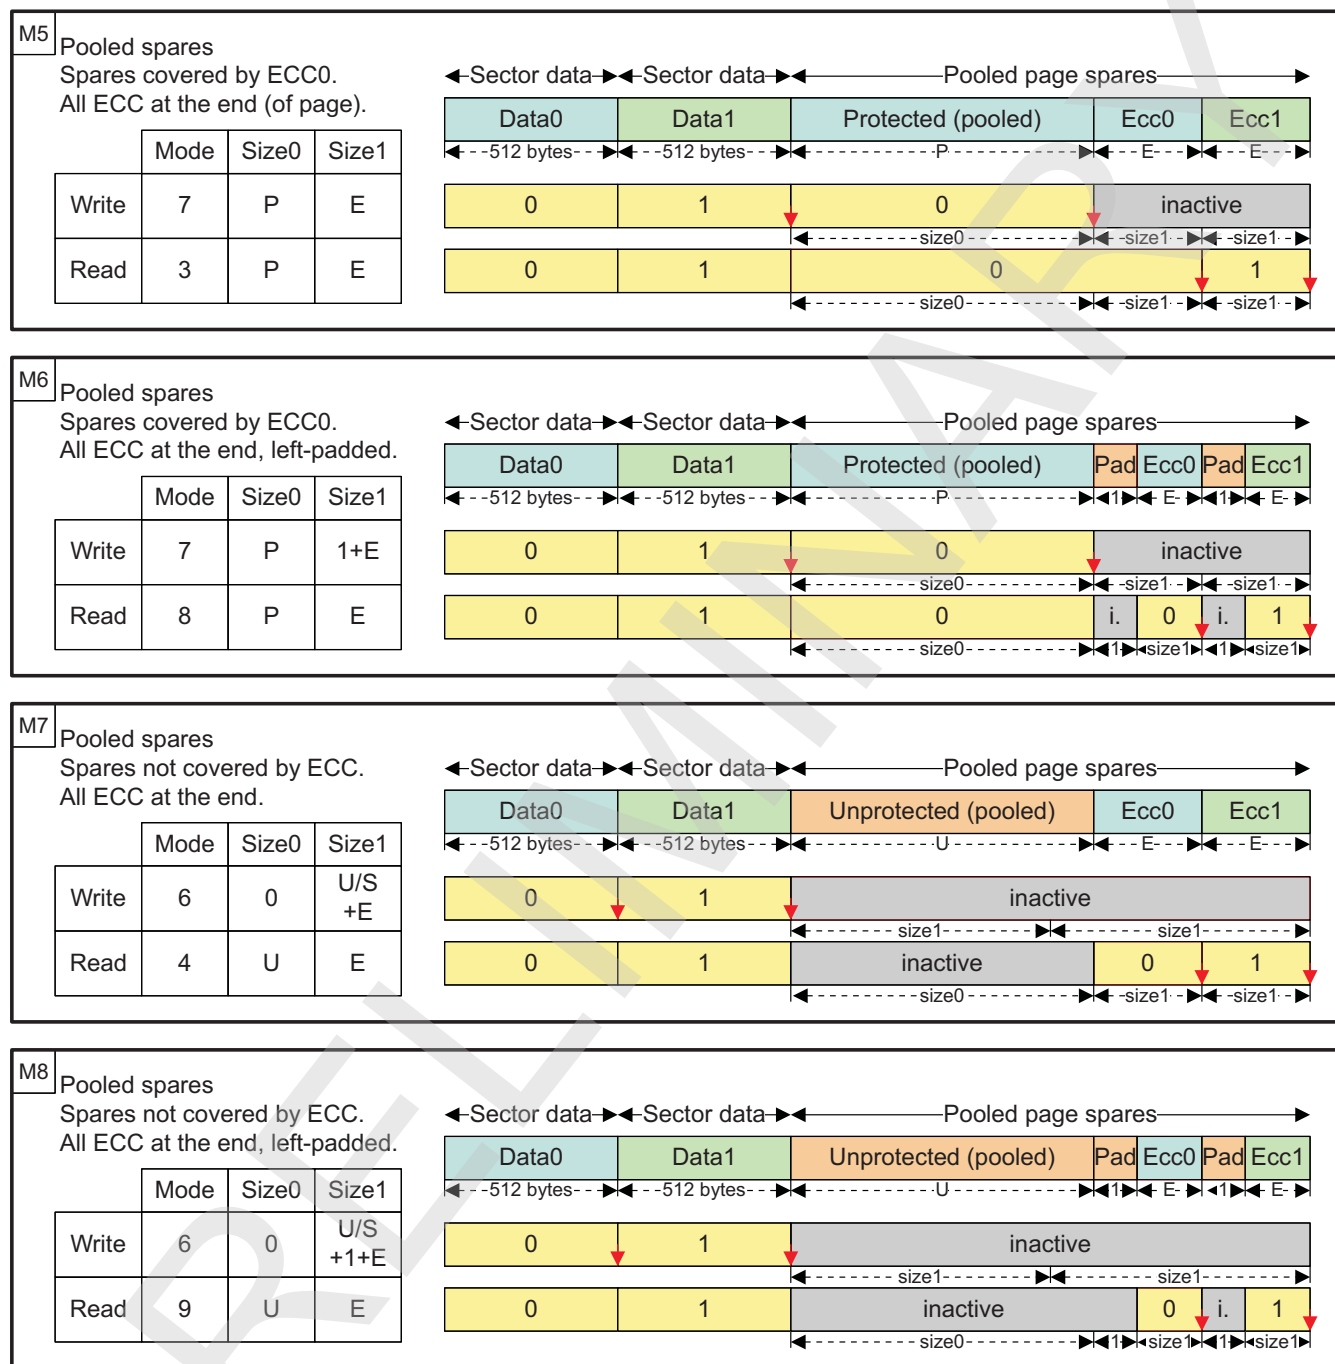

gpmc-033

### 15.4.4.13.3.2.3.2 Pooled Spare Mapping

In the schemes below, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0

**Figure 15-88. NAND Page Mapping and ECC: Pooled Spare Schemes**

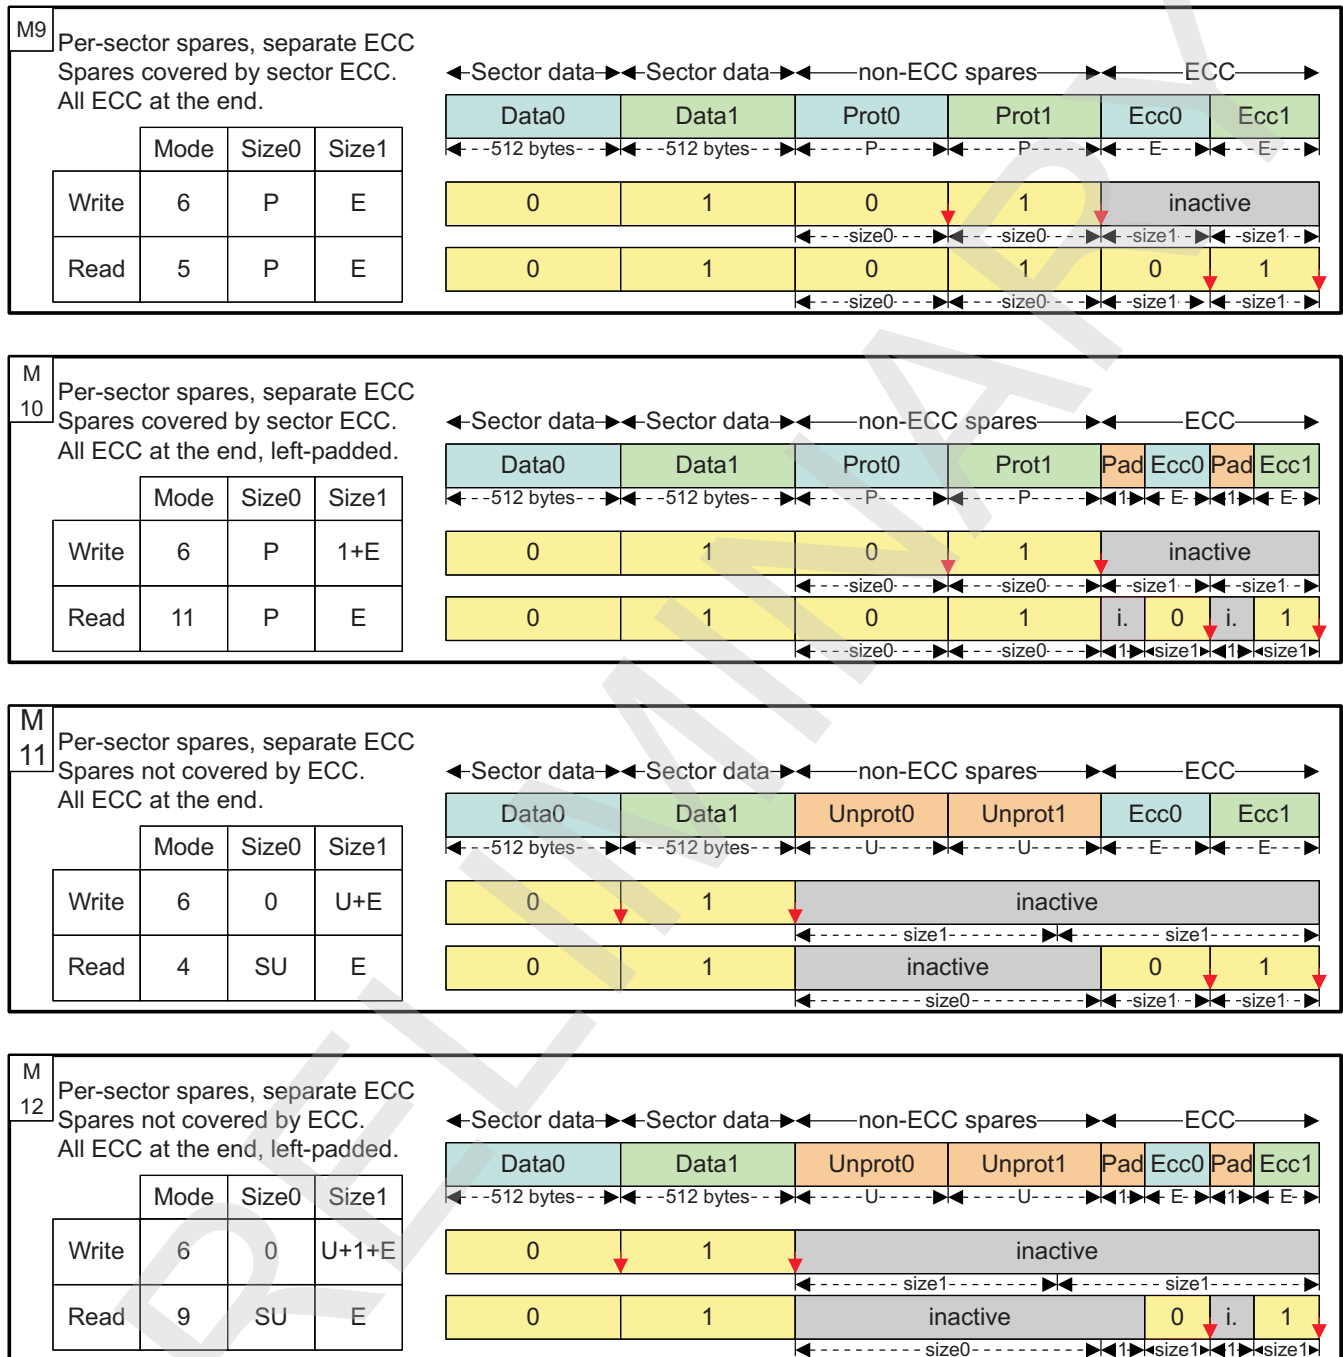

gpmc-034

**15.4.4.13.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page**

In these schemes, each 512-byte sector of the main area is associated with 2 sections of the spare area.

- ECC section, all aligned at the end of the page
- other data section, aligned before the ECCs, each of which may or may not be protected by its sectors ECC

Figure 15-89. NAND Page Mapping and ECC: Per-Sector Schemes, with Separate ECC

gpmc\_035

#### 15.4.4.13.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MPU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64 bytes (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MPU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MPU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the [GPMC\\_PREFETCH\\_CONFIG1\[23\] PFPWENROUNDROBIN](#) bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the [GPMC\\_PREFETCH\\_CONFIG1\[19:16\] PFPWWEIGHTEDPRIO](#) field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

---

**NOTE:** The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

---

#### 15.4.4.13.4.1 General Facts About the Engine Configuration

The engine can be configured only if the [GPMC\\_PREFETCH\\_CONTROL\[0\] STARTENGINE](#) bit is de-asserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the [GPMC\\_PREFETCH\\_CONFIG1\[26:24\] ENGINECSSELECTOR](#) field.

In both prefetch and write-posting modes, the engine respectively uses byte or 16-bit word access requests for an 8- or 16-bit wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes or a number of 16-bit word.

When the [GPMC\\_PREFETCH\\_CONFIG1\[7\]](#) ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the [GPMC\\_NAND\\_COMMAND\\_i](#), [GPMC\\_NAND\\_ADDRESS\\_i](#), and [GPMC\\_NAND\\_DATA\\_i](#) registers (where i = 0 to 3).

The FIFO entry on the L3 interconnect port can be accessed with Byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32-bit wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The [GPMC\\_PREFETCH\\_STATUS\[30:24\]](#) FIFOPointer field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The [GPMC\\_PREFETCH\\_STATUS\[13:0\]](#) COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPointer and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPointer equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPointer equals 0, that is, the FIFO is full, a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

#### 15.4.4.13.4.2 Prefetch Mode

The prefetch mode is selected when the [GPMC\\_PREFETCH\\_CONFIG1\[0\]](#) ACCESSMODE bit is cleared.

The MPU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the [GPMC\\_PREFETCH\\_CONTROL\[0\]](#) STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the [GPMC\\_PREFETCH\\_CONFIG1\[3\]](#) SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see [Section 15.4.4.13.2.2, Ready Pin Monitored by Hardware Interrupt](#). The [GPMC\\_PREFETCH\\_CONFIG1\[5:4\]](#) WAITPINSELECTOR field selects which gpmc\_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by [GPMC\\_PREFETCH\\_CONFIG2\[13:0\]](#) TRANSFERCOUNT field.

**Table 15-234. Prefetch Mode Configuration**

Bit Field	Register	Value	Comments
STARTENGINE	<a href="#">GPMC_PREFETCH_CONTROL[0]</a>	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	<a href="#">GPMC_PREFETCH_CONFIG1[26:24]</a>	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.

**Table 15-234. Prefetch Mode Configuration (continued)**

Bit Field	Register	Value	Comments
ACCESSMODE	<a href="#">GPMC_PREFETCH_CONFIG1</a> [0]	0	Selects prefetch mode
FIFOTHRESHOLD	<a href="#">GPMC_PREFETCH_CONFIG1</a> [14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	<a href="#">GPMC_PREFETCH_CONFIG2</a> [13:0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	<a href="#">GPMC_PREFETCH_CONFIG1</a> [3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	<a href="#">GPMC_PREFETCH_CONFIG1</a> [17:16]	0 to 1	Selects wait pin edge detector (if <a href="#">GPMC_PREFETCH_CONFIG1</a> [3] SYNCHROMODE = 0x1)
ENABLEOPTIMIZEDACCESS	<a href="#">GPMC_PREFETCH_CONFIG1</a> [27]	0/1	See <a href="#">Section 15.4.4.13.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine</a> .
CYCLEOPTIMIZATION	<a href="#">GPMC_PREFETCH_CONFIG1</a> [30:28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	<a href="#">GPMC_PREFETCH_CONFIG1</a> [7]	1	Engine enabled
STARTENGINE	<a href="#">GPMC_PREFETCH_CONTROL</a> [0]	1	Starts the prefetch engine

#### 15.4.4.13.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an sDMA channel.

In MPU draining mode, the FIFO status can be monitored through the [GPMC\\_PREFETCH\\_STATUS](#)[30:24] FIFOPINTER field or through the [GPMC\\_PREFETCH\\_STATUS](#)[16] FIFOTHRESHOLDSTATUS bit. The FIFOPINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the [GPMC\\_IRQENABLE](#)[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the [GPMC\\_IRQSTATUS](#)[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the [GPMC\\_PREFETCH\\_STATUS](#)[13:0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the [GPMC\\_IRQENABLE](#)[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the [GPMC\\_IRQSTATUS](#)[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

---

**NOTE:** The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

---

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the [GPMC\\_PREFETCH\\_CONFIG1\[2\]](#) DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

#### 15.4.4.13.4.4 Write-Posting Mode

The write-posting mode is selected when the [GPMC\\_PREFETCH\\_CONFIG1\[0\]](#) ACCESSMODE bit is set.

The MPU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the [GPMC\\_PREFETCH\\_CONTROL\[0\]](#) STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the [GPMC\\_PREFETCH\\_CONFIG1\[3\]](#) SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed [GPMC\\_PREFETCH\\_CONFIG2\[13:0\]](#) TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

**Table 15-235. Write-Posting Mode Configuration**

Bit Field	Register	Value	Comments
STARTENGINE	<a href="#">GPMC_PREFETCH_CONTROL[0]</a>	0	Write-posting engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	<a href="#">GPMC_PREFETCH_CONFIG1[26:24]</a>	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	<a href="#">GPMC_PREFETCH_CONFIG1[0]</a>	1	Selects write-posting mode
FIFOTHRESHOLD	<a href="#">GPMC_PREFETCH_CONFIG1[14:8]</a>		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	<a href="#">GPMC_PREFETCH_CONFIG2[13:0]</a>		Selects the number of bytes to be read or written by the engine from/to the selected chip-select

**Table 15-235. Write-Posting Mode Configuration (continued)**

Bit Field	Register	Value	Comments
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See <a href="#">Section 15.4.4.13.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine.</a>
CYCLOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

#### 15.4.4.13.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPINTER or through the [GPMC\\_PREFETCH\\_STATUS](#)[16] FIFOTHRESHOLDSTATUS bit. FIFOPINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the [GPMC\\_IRQENABLE](#)[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the [GPMC\\_IRQSTATUS](#)[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the [GPMC\\_PREFETCH\\_STATUS](#)[13:0] COUNTVALUE field. COUNTVALUE indicates the current number of remaining data to be written based on the TRANSFERCOUNT value. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the [GPMC\\_IRQENABLE](#)[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the [GPMC\\_IRQSTATUS](#)[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

---

**NOTE:** The COUNTVALUE value is only valid if the write-posting engine is active and started, and an interrupt is only issued when COUNTVALUE reaches 0, that is, when the posting engine automatically goes from active to inactive.

---

In DMA filling mode, the DMAMode bit field in the [GPMC\\_PREFETCH\\_CONFIG1](#)[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

#### 15.4.4.13.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS

signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC\_NAND\_DATA\_i location, i = 0 to 3) are never optimized.

The GPMC\_PREFETCH\_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC\_PREFETCH\_CONFIG1[30:28] CYCLEOPTIMIZATION field defines the number of GPMC\_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

Figure 15-90 highlights that, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC\_PREFETCH\_CONFIG1[30:28] CYCLEOPTIMIZATION field.

Figure 15-90. NAND Read Cycle Optimization Timing Description

gpmc-036

#### 15.4.4.13.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the [GPMC\\_PREFETCH\\_CONFIG1\[23\]](#) PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the [GPMC\\_PREFETCH\\_CONFIG1\[19:16\]](#) PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

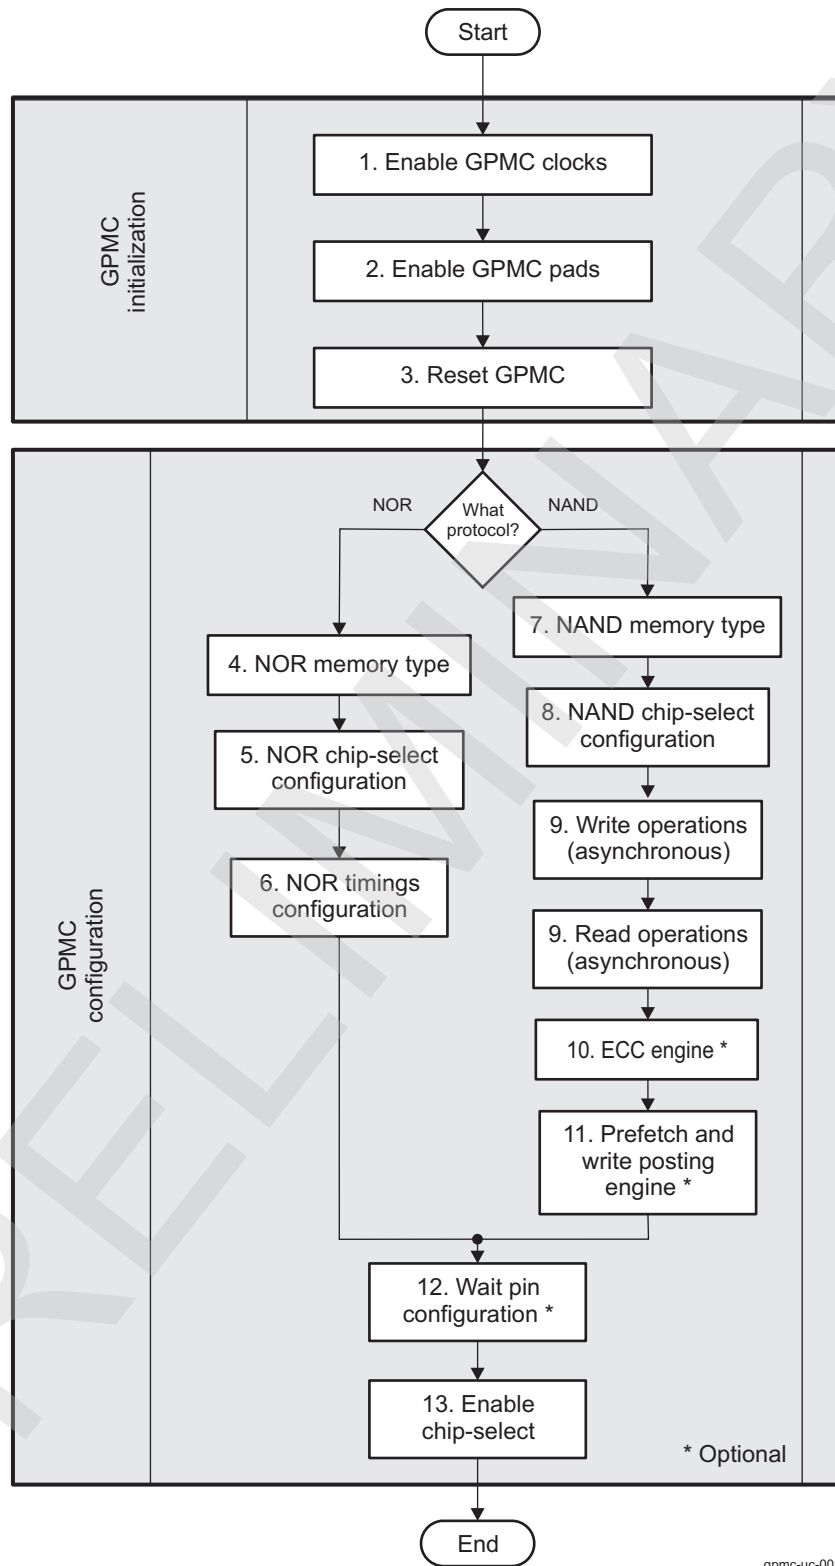

## 15.4.5 GPMC Basic Programming Model

### 15.4.5.1 GPMC High Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top down approach to users that need to configure the GPMC module.

[Figure 15-91](#), [Table 15-236](#), [Table 15-237](#) and [Table 15-238](#) show a programming model top level diagram for the GPMC, and the description of each step. Each block of the diagram is detailed in one of the following subsections through a set of registers to configure.

Figure 15-91. Programming Model Top Level Diagram

**Table 15-241. Reset GPMC**

Sub-process Name	Register / Bit Field	Value
Start a software reset	GPMC_SYSCONFIG[1] SOFTRESET	0x1
Wait until	GPMC_SYSSTATUS[0] RESETDONE =	0x1

### 15.4.5.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC.

**Table 15-242. NOR Memory Type**

Sub-process Name	Register / Bit Field	Value
Set the NOR protocol	GPMC_CONFIG1_i[11:10] DEVICETYPE	0x0
Set a device size	GPMC_CONFIG1_i[13:12] DEVICESIZE	x
Select an address and data multiplexing protocol	GPMC_CONFIG1_i[9] MUXADDDATA	x
Set the attached device page length	GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH	x
Set the wrapping burst capabilities	GPMC_CONFIG1_i[31] WRAPBURST	x
Select a timing signals latencies factor	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency <sup>(1)</sup>	GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER	x
Choose an output clock activation time <sup>(1)</sup>	GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations <sup>(1)</sup>	GPMC_CONFIG1_i[30] READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations	GPMC_CONFIG1_i[27] WRITETYPE	x

<sup>(1)</sup> Only applies to synchronous configurations (or non-multiplexed async for the multiple access one).

**Table 15-243. NOR Chip-Select Configuration**

Sub-process Name	Register / Bit Field	Value
Select the chip-select base address	GPMC_CONFIG7_[5:0] BASEADDRESS	x
Select the chip-select mask address	GPMC_CONFIG7_[11:8] MASKADDRESS	x

**Table 15-244. NOR Timings Configuration**

Sub-process Name	Register / Bit Field	Value
Configure adequate timing parameters in various memory modes	See <a href="#">Section 15.4.5.6, GPMC Timing Parameters</a>	

**Table 15-245. Wait Pin Configuration**

Sub-process Name	Register / Bit Field	Value
Enable or disable wait pin monitoring for read operations	GPMC_CONFIG1_[22] WAITREADMONITORING	x
Enable or disable wait pin monitoring for write operations	GPMC_CONFIG1_[21] WAITWRITEMONITORING	x
Select a wait pin monitoring time	GPMC_CONFIG1_[19:18] WAITMONITORINGTIME	x
Choose the input wait pin for the chip-select	GPMC_CONFIG1_[17:16] WAITPINSELECT	x

**Table 15-246. Enable Chip-Select**

Sub-process Name	Register / Bit Field	Value
When all parameters are configured, enable the chip-select	GPMC_CONFIG7_[6] CSVALID	x

#### 15.4.5.4 GPMC Configuration in NAND mode

This section gives a generic configuration for parameters related to the NAND memory connected to the GPMC.

**Table 15-247. NAND Memory Type**

Sub-process Name	Register / Bit Field	Value
Set the NAND protocol	GPMC_CONFIG1_[11:10] DEVICETYPE	0x2
Set a device size	GPMC_CONFIG1_[13:12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device	GPMC_CONFIG1_[9] MUXADDDATA	0x0
Select a timing signals latencies factor	GPMC_CONFIG1_[4] TIMEPARAGRANULARITY	x
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations	See <a href="#">Section 15.4.5.5, Set Memory Access</a>	x

**Table 15-248. NAND Chip-Select Configuration**

Sub-process Name	Register / Bit Field	Value
Select the chip-select base address	GPMC_CONFIG7_[5:0] BASEADDRESS	x
Select the chip-select minimum granularity (16M bytes)	GPMC_CONFIG7_[11:8] MASKADDRESS	x

**Table 15-249. Asynchronous Read and Write Operations**

Sub-process Name	Register / Bit Field	Value
Configure adequate timing parameters in asynchronous modes	See <a href="#">Section 15.4.5.6, GPMC Timing Parameters</a>	

**Table 15-250. ECC Engine**

Sub-process Name	Register / Bit Field	Value
Select the ECC result register where the first ECC computation is stored (Only applies to Hamming)	GPMC_ECC_CONTROL[3:0] ECCPOINTER	x <sup>(1)</sup>

<sup>(1)</sup> This parameter depends on the numbers of sectors in a page.

**Table 15-250. ECC Engine (continued)**

Sub-process Name	Register / Bit Field	Value
Clear all ECC result registers	GPMC_ECC_CONTROL[8] ECCCLEAR	Write '1' to clear.
Define ECCSIZE0 and ECCSIZE1	GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 and [29:22] ECCSIZE1	x <sup>(2)</sup>
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1)	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZ where j = 1 to 9	x
Select the chip-select where ECC is computed	GPMC_ECC_CONFIG[3:1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use	GPMC_ECC_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation	GPMC_ECC_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process	GPMC_ECC_CONFIG[13:12] ECCBCHTSEL and GPMC_ECC_CONFIG[6:4] ECCTOPSECTOR	x
Enable the ECC computation	GPMC_ECC_CONFIG[0] ECCENABLE	0x1

<sup>(2)</sup> Depends on the size of each sector in the NAND page.

**Table 15-251. Prefetch and Write-Posting Engine**

Sub-process Name	Register / Bit Field	Value
Disable the engine before configuration	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x0
Select the chip-select associated with a NAND device where the prefetch engine is active	GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1[0] ACCESSMODE	x
Select the threshold used to issue a DMA request	GPMC_PREFETCH_CONFIG1[14:8] FIFOTHRESHOLD	x
Select either DMA synchronized mode or software manual mode.	GPMC_PREFETCH_CONFIG1[2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode	GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR	x
Enter a number of clock cycles removed to timing parameters (For all back-to-back accesses to the NAND flash but not the first one)	GPMC_PREFETCH_CONFIG1[30:28] CYCLOPTIMIZATION	x
Enable the prefetch postwrite engine	GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE	0x1
Select the number of bytes to be read or written by the engine to the selected chip-select	GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT	x
Start the prefetch engine	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x1

**Table 15-252. Wait Pin Configuration**

Sub-process Name	Register / Bit Field	Value
Selects when the engine starts the access to CS	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode	GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR	x

**Table 15-253. Enable Chip-Select**

Sub-process Name	Register / Bit Field	Value
When all parameters are configured, enable the chip-select	GPMC_CONFIG7_[6] CSVALID	x

### 15.4.5.5 Set Memory Access

This section details the bit field to configure to set the GPMC in various memory modes.

**Table 15-254. Mode Parameters Check List Table**

Register	Bit	Bit field name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
<a href="#">GPMC_CONFIG1_i</a>	30	READMULTIPLE	0x0	-	0x1 <sup>(1)</sup>	N/S	0x0	-	0x1	-
<a href="#">GPMC_CONFIG1_i</a>	29	READTYPE	0x0	-	0x0 <sup>(1)</sup>	N/S	0x1	-	0x1	-
<a href="#">GPMC_CONFIG1_i</a>	28	WRITEMULTIPLE	-	0x0	- <sup>(1)</sup>	N/S	-	0x0	-	0x1
<a href="#">GPMC_CONFIG1_i</a>	27	WRITETYPE	-	0x0	- <sup>(1)</sup>	N/S	-	0x1	-	0x1

<sup>(1)</sup> Multiple read is not supported in address/data- and AAD-multiplexed modes. Multiple read is supported in Nonmultiplexed mode.

**Table 15-255. Access Type Parameters Check List Table**

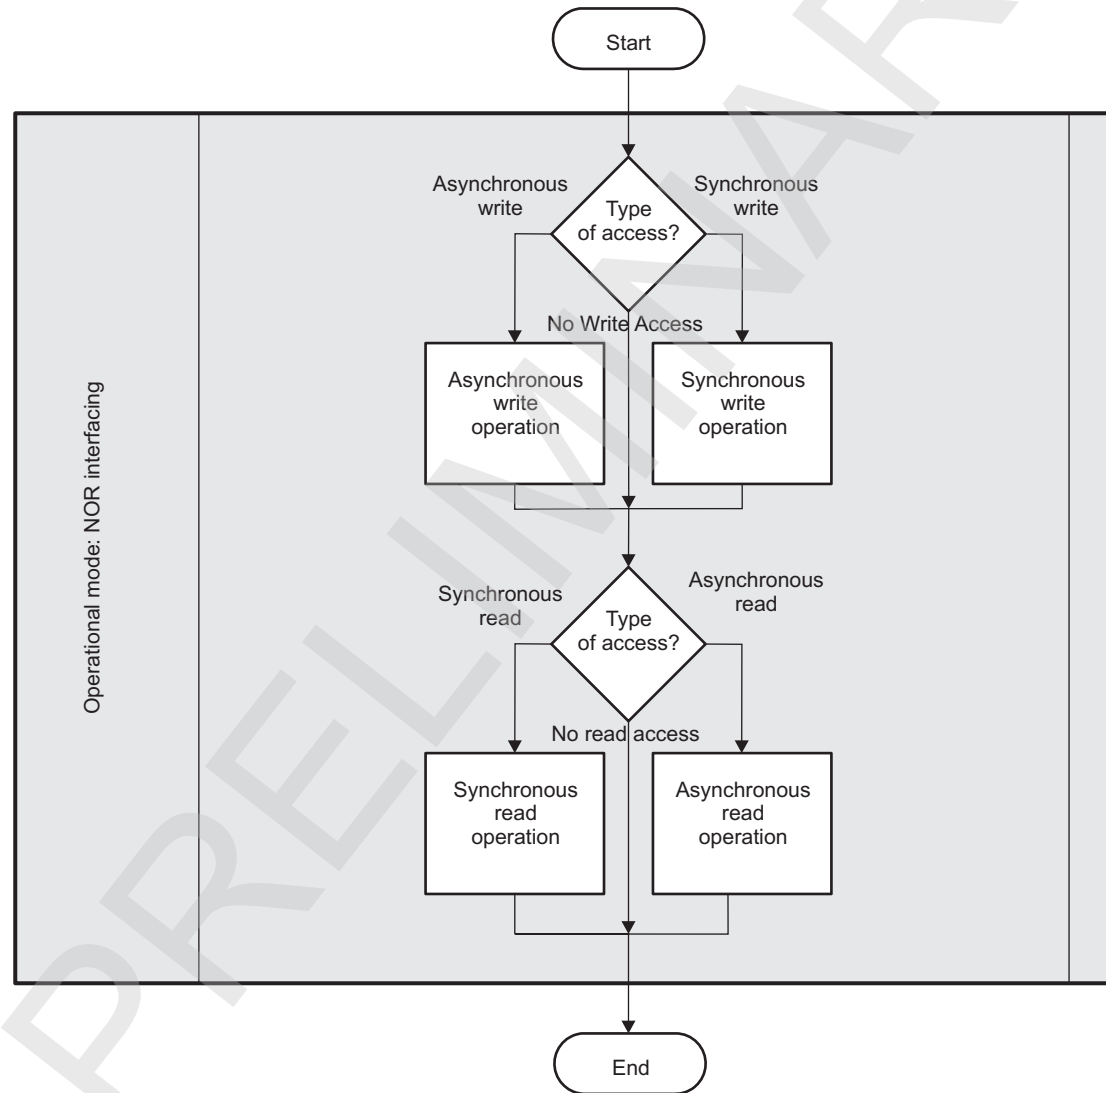

Register	Bit	Bit field name	Access Type		
			Non-mux	Address /Data Mux	AAD-mux
<a href="#">GPMC_CONFIG1_i</a>	9:8	MUXADDDATA	0x0	0x2	0x1

PRELIMINARY

### 15.4.5.6.1 GPMC Timing Parameters Formulas

This section intends to help the user to calculate the GPMC timing bit fields values. Formulas are not listed exhaustively.

The section details:

- NAND Flash Interface Timing Parameters Formulas
- Synchronous NOR Flash Timing Parameters Formulas
- Asynchronous NOR Flash Timing Parameters Formulas

#### 15.4.5.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to use in order to calculate NAND timing parameters. This is the case when `GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x2`. [Table 15-257](#) details NAND timing parameters.

**Table 15-257. NAND Formulas Description Table**

Configuration Parameter	Unit	Description
A	ns	Pulse duration - gpmc_nwe valid time
B	ns	Delay time - gpmc_ncs valid to gpmc_nwe valid
C	ns	Delay time - gpmc_nbe0_cle/gpmc_nadv_ale high to gpmc_nwe valid
D	ns	Delay time - gpmc_ad[15:0] valid to gpmc_nwe valid
E	ns	Delay time - gpmc_nwe invalid to gpmc_ad[15:0] invalid
F	ns	Delay time - gpmc_nwe invalid to gpmc_nbe0_cle/gpmc_nadv_ale invalid
G	ns	Delay time - gpmc_nwe invalid to gpmc_ncs invalid
H	ns	Cycle time - Write cycle time
I	ns	Delay time - gpmc_ncs valid to gpmc_noe valid
J	ns	Setup time - gpmc_ad[15:0] valid to gpmc_noe invalid
K	ns	Pulse duration - gpmc_noe valid time
L	ns	Cycle time - Read cycle time
M	ns	Delay time - gpmc_noe invalid to gpmc_ncs invalid

The configuration parameters are calculated through the following formulas.

$$A = (WEOffTime - WEOnTime) * (TimeParaGranularity + 1) * GPMC\_FCLK \text{ period}$$

$$B = ((WEOnTime - CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEEExtraDelay - CSEExtraDelay)) * GPMC\_FCLK \text{ period}$$

$$C = ((WEOnTime - ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEEExtraDelay - ADVExtraDelay)) * GPMC\_FCLK \text{ period}$$

$$D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEEExtraDelay) * GPMC\_FCLK \text{ period}$$

$$E = (WrCycleTime - WEOffTime * (TimeParaGranularity + 1) - 0.5 * WEEExtraDelay) * GPMC\_FCLK \text{ period}$$

$$F = (ADVWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay - WEEExtraDelay)) * GPMC\_FCLK \text{ period}$$

$$G = (CSWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSEExtraDelay - WEEExtraDelay)) * GPMC\_FCLK \text{ period}$$

$$H = WrCycleTime * (1 + TimeParaGranularity) * GPMC\_FCLK \text{ period}$$

$$I = ((OEOnTime - CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (OEEExtraDelay - CSEExtraDelay)) * GPMC\_FCLK \text{ period}$$

$$J = ((AccessTime - OEOffTime) * (TimeParaGranularity + 1) - 0.5 * OEEExtraDelay) * GPMC\_FCLK \text{ period}$$

$$K = (OEOffTime - OEOnTime) * (1 + TimeParaGranularity) * GPMC\_FCLK \text{ period}$$

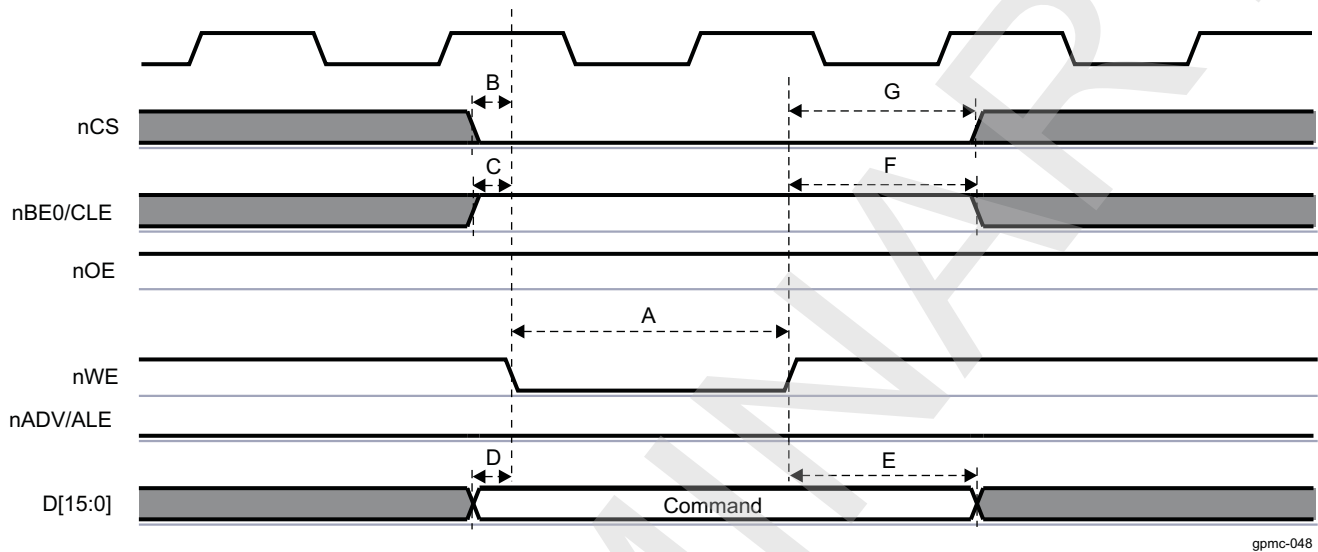

$$L = RdCycleTime * (1 + TimeParaGranularity) * GPMC\_FCLK \text{ period}$$

$$M = (\text{CSRdOffTime} - \text{OEOffTime} * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{CSExtraDelay} - \text{OEEExtraDelay}) * \text{GPMC\_FCLK period}$$

Figure 15-93 shows a command latch cycle timing simplified example where formulas are associated with signal waves.

Figure 15-93. NAND Command Latch Cycle Timing Simplified Example

15.4.5.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate synchronous NOR timing parameters. This is the case when GPMC\_CONFIG1\_[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to synchronous mode.

Table 15-258. Synchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - gpmc_ncs low
B	ns	Delay time - address bus valid to gpmc_clk first edge Delay time - gpmc_nbe0_cle/gpmc_nbe1 valid to gpmc_clk first edge
C	ns	Pulse duration - gpmc_nbe0_cle/gpmc_nbe1 low
D	ns	Delay time - gpmc_clk rising edge to gpmc_nbe0_cle/gpmc_nbe1 invalid Delay time - gpmc_clk rising edge to gpmc_nadv_ale invalid
E	ns	Delay time - gpmc_clk rising edge to gpmc_ncs invalid Delay time - gpmc_clk rising edge to gpmc_noe invalid
F	ns	Delay time - gpmc_clk rising edge to gpmc_ncs transition
G	ns	Delay time - gpmc_clk rising edge to gpmc_nadv_ale transition
H	ns	Delay time - gpmc_clk rising edge to gpmc_noe transition
I	ns	Delay time - gpmc_clk rising edge to gpmc_nwe transition
J	ns	Delay time - gpmc_clk rising edge to gpmc_ad data bus transition Delay time - gpmc_clk rising edge to gpmc_nbe0_cle/gpmc_nbe1 transition
K	ns	Pulse duration - gpmc_nadv_ale low
L	ns	Delay time - gpmc_wait invalid to first data latching gpmc_clk edge

The configuration parameters are calculated through the following formulas.

1. For single read accesses:
  - A = (CSRDOFFTIME - CSONTIME) \* (TIMEPARAGRANULARITY + 1) \* GPMC\_FCLK period
  - C = RDCYCLETIME \* (TIMEPARAGRANULARITY + 1) \* GPMC\_FCLK period
  - D = (RDCYCLETIME - ACCESSTIME) \* GPMC\_FCLK period
  - E = (CSRDOFFTIME - ACCESSTIME) \* GPMC\_FCLK period
2. For burst read accesses (where n is the page burst access number):
  - A = (CSRDOFFTIME - CSONTIME + (n - 1) \* PAGEBURSTACCESSTIME) \* (TIMEPARAGRANULARITY + 1) \* GPMC\_FCLK period
  - C = (RDCYCLETIME + (n - 1) \* PAGEBURSTACCESSTIME) \* (TIMEPARAGRANULARITY + 1) \* GPMC\_FCLK period
  - D = (RDCYCLETIME - (ACCESSTIME + (n - 1) \* PAGEBURSTACCESSTIME)) \* GPMC\_FCLK period
  - E = (CSRDOFFTIME - (ACCESSTIME + (n - 1) \* PAGEBURSTACCESSTIME)) \* GPMC\_FCLK period
3. For burst write accesses (where n is the page burst access number):
  - A = (CSWROFFTIME - CSONTIME + (n - 1) \* PAGEBURSTACCESSTIME) \* (TIMEPARAGRANULARITY + 1) \* GPMC\_FCLK period
  - C = (WRCYCLETIME + (n - 1) \* PAGEBURSTACCESSTIME) \* (TIMEPARAGRANULARITY + 1) \* GPMC\_FCLK period
  - D = (WRCYCLETIME - (ACCESSTIME + (n - 1) \* PAGEBURSTACCESSTIME)) \* GPMC\_FCLK period
  - E = (CSWROFFTIME - (ACCESSTIME + (n - 1) \* PAGEBURSTACCESSTIME)) \* GPMC\_FCLK period
4. For all accesses:
  - For nCS falling edge (CS activated):
    - Case where `GPMC_CONFIG1_j[1:0] GPMCFCLKDIVIDER = 0x0`:  
F = 0.5 \* CSEXTRADELAY \* GPMC\_FCLK period
    - Case where `GPMCFCLKDIVIDER = 0x1`:  
F = 0.5 \* CSEXTRADELAY \* GPMC\_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)  
F = (1 + 0.5 \* CSEXTRADELAY) \* GPMC\_FCLK period otherwise.
    - Case where `GPMCFCLKDIVIDER = 0x2`:  
F = 0.5 \* CSEXTRADELAY \* GPMC\_FCLK period, when (CSONTIME - CLKACTIVATIONTIME) is a multiple of 3  
F = (1 + 0.5 \* CSEXTRADELAY) \* GPMC\_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3  
F = (2 + 0.5 \* CSEXTRADELAY) \* GPMC\_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3
  - For nCS rising edge (CS deactivated) in reading mode:
    - Case where `GPMC_CONFIG1_j[1:0] GPMCFCLKDIVIDER = 0x0`:  
F = 0.5 \* CSEXTRADELAY \* GPMC\_FCLK period
    - Case where `GPMCFCLKDIVIDER = 0x1`:  
F = 0.5 \* CSEXTRADELAY \* GPMC\_FCLK period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)  
F = (1 + 0.5 \* CSEXTRADELAY) \* GPMC\_FCLK period otherwise.
    - Case where `GPMCFCLKDIVIDER = 0x2`:  
F = 0.5 \* CSEXTRADELAY \* GPMC\_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3  
F = (1 + 0.5 \* CSEXTRADELAY) \* GPMC\_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3  
F = (2 + 0.5 \* CSEXTRADELAY) \* GPMC\_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3
  - For nCS rising edge (CS deactivated) in writing mode:
    - Case where `GPMC_CONFIG1_j[1:0] GPMCFCLKDIVIDER = 0x0`:  
F = 0.5 \* CSEXTRADELAY \* GPMC\_FCLK period
    - Case where `GPMCFCLKDIVIDER = 0x1`:  
F = 0.5 \* CSEXTRADELAY \* GPMC\_FCLK period, when (CLKACTIVATIONTIME and CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)  
F = (1 + 0.5 \* CSEXTRADELAY) \* GPMC\_FCLK period otherwise.
    - Case where `GPMCFCLKDIVIDER = 0x2`:  
F = 0.5 \* CSEXTRADELAY \* GPMC\_FCLK period, when (CSWROFFTIME -

CLKACTIVATIONTIME) is a multiple of 3

$F = (1 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK$  period, when (CSWROFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

$F = (2 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK$  period, when (CSWROFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nADV falling edge (nADV activated):

- Case where  $GPMC\_CONFIG1\_j[1:0]$  GPMCFCLKDIVIDER = 0x0:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period
- Case where GPMCFCLKDIVIDER = 0x1:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when (CLKACTIVATIONTIME and ADVONTIME are odd) or (CLKACTIVATIONTIME and ADVONTIME are even)  
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when (ADVONTIME - CLKACTIVATIONTIME) is a multiple of 3  
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when (ADVONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3  
 $G = (2 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when (ADVONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nADV rising edge (nADV deactivated) in reading mode:

- Case where  $GPMC\_CONFIG1\_j[1:0]$  GPMCFCLKDIVIDER = 0x0:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period
- Case where GPMCFCLKDIVIDER = 0x1:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when (CLKACTIVATIONTIME and ADVRDOFFTIME are odd) or (CLKACTIVATIONTIME and ADVRDOFFTIME are even)  
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when (ADVRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3  
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3  
 $G = (2 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nADV rising edge (nADV deactivated) in writing mode:

- Case where  $GPMC\_CONFIG1\_j[1:0]$  GPMCFCLKDIVIDER = 0x0:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period
- Case where GPMCFCLKDIVIDER = 0x1:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when (CLKACTIVATIONTIME and ADVWROFFTIME are odd) or (CLKACTIVATIONTIME and ADVWROFFTIME are even)  
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK$  period, when (ADVWROFFTIME - CLKACTIVATIONTIME) is a multiple of 3  
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when (ADVWROFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3  
 $G = (2 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK$  period, when (ADVWROFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nOE falling edge (nOE activated):

- Case where  $GPMC\_CONFIG1\_j[1:0]$  GPMCFCLKDIVIDER = 0x0:  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK$  period
- Case where GPMCFCLKDIVIDER = 0x1:  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK$  period, when (CLKACTIVATIONTIME and OEONTIME are odd) or (CLKACTIVATIONTIME and OEONTIME are even)  
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK$  period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK$  period, when (OEONTIME - CLKACTIVATIONTIME) is a multiple of 3  
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK$  period, when (OEONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

- $H = (2 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK$  period, when  $(OEONTIME - CLKACTIVATIONTIME - 2)$  is a multiple of 3
- For nOE rising edge (nOE deactivated):
- Case where  $GPMC\_CONFIG1\_j[1:0]$  GPMCFCLKDIVIDER = 0x0:  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK$  period
  - Case where GPMCFCLKDIVIDER = 0x1:  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK$  period, when  $(CLKACTIVATIONTIME$  and  $OEOFFTIME$  are odd) or  $(CLKACTIVATIONTIME$  and  $OEOFFTIME$  are even)  
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK$  period otherwise.
  - Case where GPMCFCLKDIVIDER = 0x2:  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK$  period, when  $(OEOFFTIME - CLKACTIVATIONTIME)$  is a multiple of 3  
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK$  period, when  $(OEOFFTIME - CLKACTIVATIONTIME - 1)$  is a multiple of 3  
 $H = (2 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK$  period, when  $(OEOFFTIME - CLKACTIVATIONTIME - 2)$  is a multiple of 3
- For nWE falling edge (nWE activated):
- Case where  $GPMC\_CONFIG1\_j[1:0]$  GPMCFCLKDIVIDER = 0x0:  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK$  period
  - Case where GPMCFCLKDIVIDER = 0x1:  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK$  period, when  $(CLKACTIVATIONTIME$  and  $WEONTIME$  are odd) or  $(CLKACTIVATIONTIME$  and  $WEONTIME$  are even)  
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK$  period otherwise.
  - Case where GPMCFCLKDIVIDER = 0x2:  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK$  period, when  $(WEONTIME - CLKACTIVATIONTIME)$  is a multiple of 3  
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK$  period, when  $(WEONTIME - CLKACTIVATIONTIME - 1)$  is a multiple of 3  
 $I = (2 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK$  period, when  $(WEONTIME - CLKACTIVATIONTIME - 2)$  is a multiple of 3
- For nWE rising edge (nWE deactivated):
- Case where  $GPMC\_CONFIG1\_j[1:0]$  GPMCFCLKDIVIDER = 0x0:  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK$  period
  - Case where GPMCFCLKDIVIDER = 0x1:  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK$  period, when  $(CLKACTIVATIONTIME$  and  $WEOFFTIME$  are odd) or  $(CLKACTIVATIONTIME$  and  $WEOFFTIME$  are even)  
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK$  period otherwise.
  - Case where GPMCFCLKDIVIDER = 0x2:  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK$  period, when  $(WEOFFTIME - CLKACTIVATIONTIME)$  is a multiple of 3  
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK$  period, when  $(WEOFFTIME - CLKACTIVATIONTIME - 1)$  is a multiple of 3  
 $I = (2 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK$  period, when  $(WEOFFTIME - CLKACTIVATIONTIME - 2)$  is a multiple of 3
- For gpmc\_nadv low pulse duration:
- Read operation:  
 $K = (ADVRDOFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK$  period
  - Write operation:  
 $K = (ADVWROFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK$  period
- For gpmc\_wait invalid to first data latching gpmc\_clk edge:
- $L = WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) * GPMC\_FCLK$  period +  $GPMC\_CLK$  period

Figure 15-94 shows a synchronous NOR single read simplified example where formulas are associated with signal waves.

Figure 15-94. Synchronous NOR Single Read Simplified Example

15.4.5.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate asynchronous NOR timing parameters. This is the case when GPMC\_CONFIG1\_i[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode.

Table 15-259. Asynchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - gpmc_ncs low
B	ns	Delay time - gpmc_ncs valid to gpmc_nadv_ale invalid
C	ns	Delay time - gpmc_ncs valid to gpmc_noe invalid (single read)
D	ns	Pulse duration - address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time - gpmc_ncs valid to gpmc_nwe valid
F	ns	Delay time - gpmc_ncs valid to gpmc_nwe invalid
G	ns	Address invalid duration between 2 successive R/W accesses
H	ns	Setup time - read data valid before gpmc_noe high
I	ns	Delay time - gpmc_ncs valid to gpmc_noe invalid (burst read)
J	ns	Delay time - address bus valid to gpmc_ncs valid Delay time - data bus valid to gpmc_ncs valid Delay time - gpmc_nbe0_cle/gpmc_nbe1 valid to gpmc_ncs valid
K	ns	Delay time - gpmc_ncs valid to gpmc_nadv_ale valid
L	ns	Delay time - gpmc_ncs valid to gpmc_noe valid
M	ns	Delay time - gpmc_ncs valid to first data latching edge
N	ns	Pulse duration - gpmc_nbe0_cle/gpmc_nbe1 valid time

**Table 15-259. Asynchronous NOR Formulas Description Table (continued)**

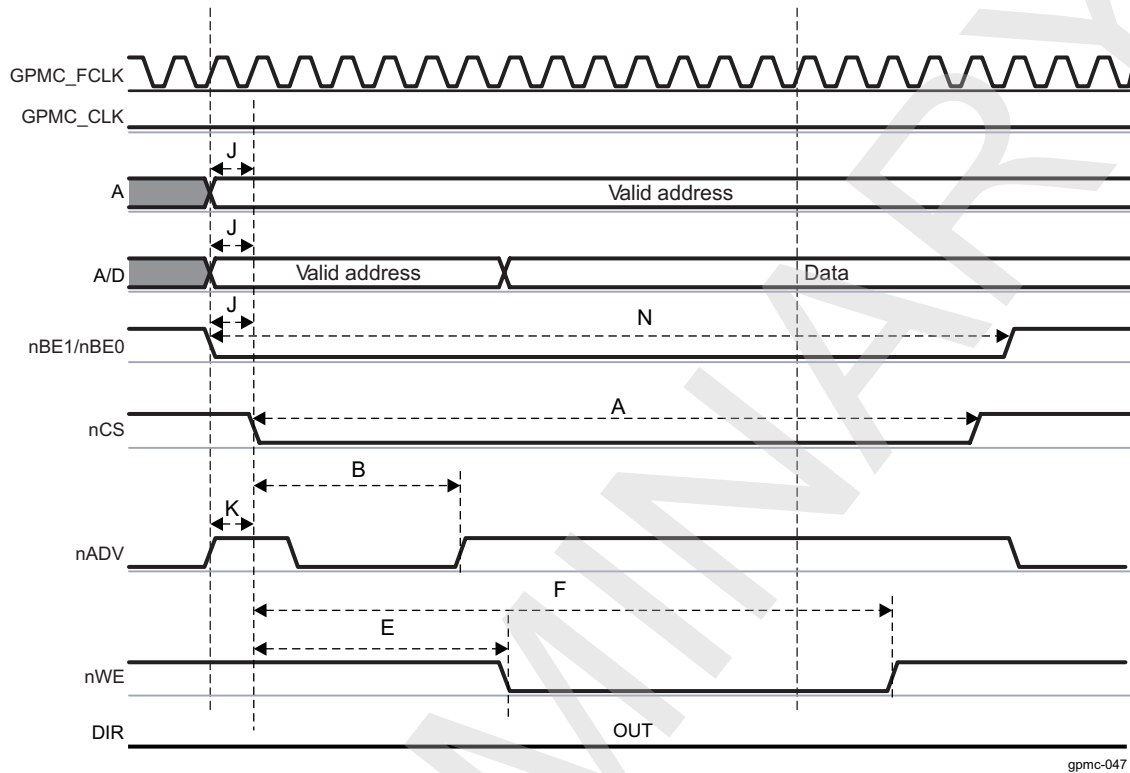

Configuration Parameter	Unit	Description
O	ns	Delay time - gpmc_ncs valid to gpmc_nadv_ale valid

The configuration parameters are calculated through the following formulas. Note that these formulas are not exhaustive.

- gpmc\_ncs low pulse:  
For single read:  $A = (\text{CSRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$   
For burst read:  $A = (\text{CSRDOFFTIME} - \text{CSONTIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$ , where N = page burst access number  
For single write:  $A = (\text{CSWROFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$   
For burst write:  $A = (\text{CSWROFFTIME} - \text{CSONTIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$ , where N = page burst access number
- gpmc\_ncs valid to gpmc\_nadv\_ale invalid delay:  
For reading:  $B = ((\text{ADVRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$   
For writing:  $B = ((\text{ADVWROFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$
- $C = ((\text{OEOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$
- $D = \text{PAGEBURSTACCESSTIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$
- $E = ((\text{WEONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{WEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$
- $F = ((\text{WEOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{WEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$
- $G = \text{CYCLE2CYCLEDELAY} * \text{GPMC\_FCLK period}$
- $H = ((\text{OEOFFTIME} - \text{ACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * \text{OEEXTRADELAY}) * \text{GPMC\_FCLK period}$
- $I = ((\text{OEOFFTIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$ , where N = page burst access number
- $J = (\text{CSONTIME} * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC\_FCLK period}$
- $K = ((\text{ADVONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$
- $L = ((\text{OEONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$
- $M = ((\text{ACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) - 0.5 * \text{CSEXTRADELAY}) * \text{GPMC\_FCLK period}$
- gpmc\_nbe0\_cle/gpmc\_nbe1 pulse:  
For single read:  $N = \text{RDCYCLETIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$   
For burst read:  $N = (\text{RDCYCLETIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$ , where N = page burst access number  
For burst write:  $N = (\text{WRCYCLETIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$ , where N = page burst access number
- $O = ((\text{WRCYCLETIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$

Figure 15-95 shows an asynchronous NOR single write simplified example where formulas are associated with signal waves.

**Figure 15-95. Asynchronous NOR Single Write Simplified Example**

**NOTE:** Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

## 15.4.6 GPMC Use Cases And Tips

### 15.4.6.1 How to Set GPMC Timing Parameters for Typical Accesses

#### 15.4.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104 MHz clock frequency
- Read access time: 80 ns

#### 15.4.6.1.2 Typical GPMC Setup

Table 15-260 lists some of the I/Os of the GPMC module.

**Table 15-260. GPMC Signals**

Signal Name	I/O	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
gpmc_clk	O	External clock provided to the external device for synchronous operations
gpmc_a[25:16]	O	Address
gpmc_ad[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
gpmc_ncsx	O	Chip-select (where x = 0, or 1)
gpmc_nadv_ale	O	Address valid enable
gpmc_noe_nre	O	Output enable (read access only)
gpmc_nwe	O	Write enable (write access only)
gpmc_wait[2:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 15-96 shows the typical connection between the GPMC module and an attached NOR Flash memory.

Figure 15-96. GPMC Connection to an External NOR Flash Memory

gpmc-037

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

15.4.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz ( f = 104 MHz; T = 9, 615 ns).

Table 15-261 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-262 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-97 shows the synchronous burst read access.

Table 15-261. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80

**Table 15-261. Useful Timing Parameters on the Memory Side (continued)**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read Access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle ( $T = 9,615$  ns). The read access time between 2 bursts of data is tBACC = 5,2 ns. Therefore, data setup time is a clock period - tBACC = 4,415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read Access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

**Table 15-262. Calculating GPMC Timing Parameters**

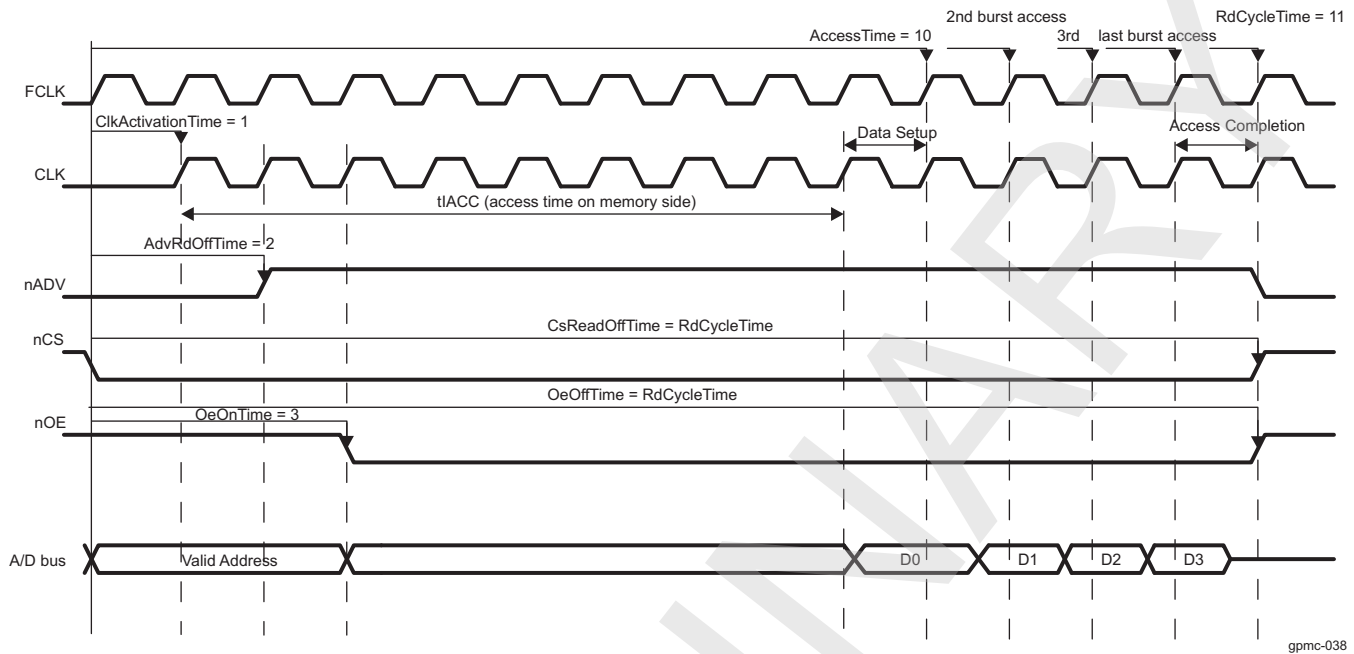

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	-	-	-	GPMCFCLKDIVIDER = 0x0
ClkActivation Time	min ( tCES, tACS)	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	94,03: (9,615 + 80 + 4,415)	10 : roundmax (94,03 / 9,615)	ACCESSTIME = 0x0A
PageBurst AccessTime	roundmax (tBACC)	roundmax (5,2)	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	AccessTime + max ( tCEZ, tOEZ)	101, 03: (94, 03 + 7)	11	RDCYCLETIME = 0x0B
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAVC <sup>(1)</sup>	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC <sup>(2)</sup>	12	2	ADVRDOFFTIME = 0x02
OeOnTime <sup>(3)</sup>	(ClkActivationTime + tACH) < OeOnTime < (ClkActivationTime + tIACC)	-	3 for instance.	OEONTIME = 0x3
OeOffTime	RdCycleTime	-	11	OEOFFTIME = 0x0B

<sup>(1)</sup> The external clock provided to the NOR flash is not yet available.

<sup>(2)</sup> AdvRdOffTime - AdvOnTime = tAVD; thus, AdvRdOffTime = tAVD + AdvOnTime = tAVD + tAVC.

<sup>(3)</sup> OeOnTime must guarantee that addresses are available. It must not exceed the availability of the first burst of data.

**Figure 15-97. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)**

**15.4.6.1.2.2 GPMC Configuration for Asynchronous Read Access**

The clock runs at 104 MHz ( f = 104 MHz; T = 9, 615 ns).

Table 15-263 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-264 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-98 shows the asynchronous read access.

**Table 15-263. AC Characteristics for Asynchronous Read Access**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

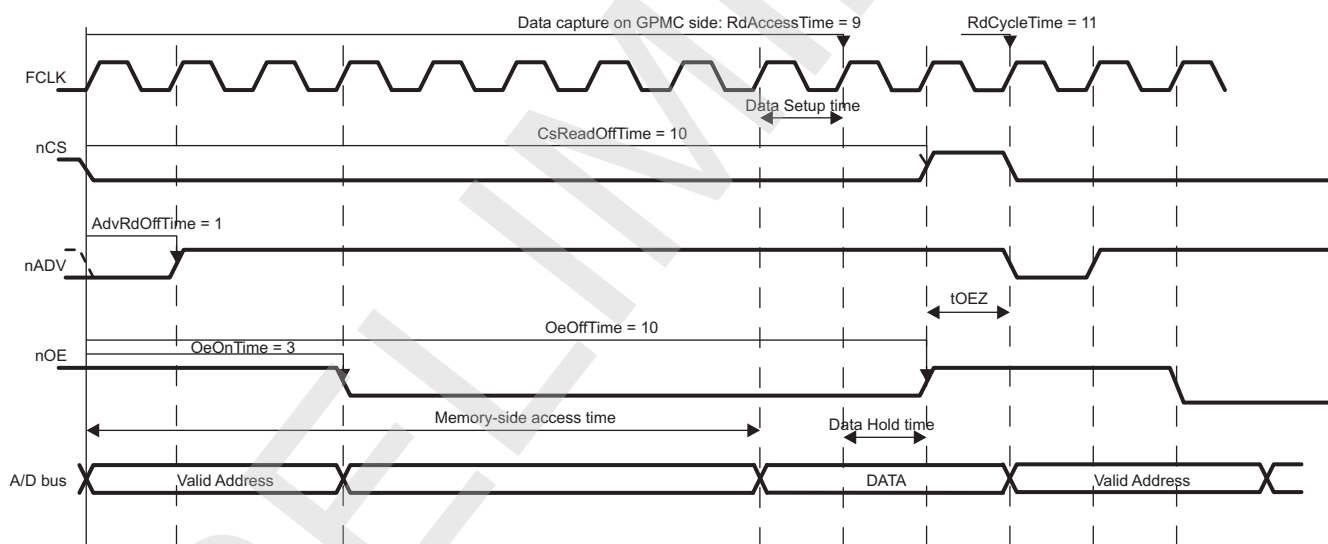

$$RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 \text{ clock cycle} + tOEZ:$$

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 15-263: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus. The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.
- To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is 1 clock cycle (that is, AccessTime + 1).

- To complete the access, nOE/nCS signals are driven to High-Z. AccessTime + 1 + tOEZ is the read cycle time.
- Addresses can now be relatched and a new read cycle begun.

**Table 15-264. GPMC Timing Parameters for Asynchronous Read Access**

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime		n/a (asynchronous mode)		
AccessTime	round max (tCE)	80	9	ACCESSTIME = 0x09
PageBurstAccess Time	n/a (single access)			
RdCycleTime	AccessTime + 1 cycle + tOEZ	96, 615	11	RDCYCLETIME = 0x0B
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	AccessTime + 1 cycle	89, 615	10	CSRDOFFTIME = 0x0A
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0x1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x01
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3 for instance	OEONTIME = 0x3
OeOffTime	AccessTime + 1 cycle	89, 615	10	OEOFFTIME = 0x0A

**Figure 15-98. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)**

gpmc-039

#### 15.4.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 15-266 shows how to calculate timings for the GPMC using the memory parameters.

Table 15-265 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 15-99 shows the synchronous burst write access.

**Table 15-265. AC Characteristics for Asynchronous Single Write ( Memory Side)**

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6

**Table 15-265. AC Characteristics for Asynchronous Single Write ( Memory Side) (continued)**

AC Characteristics on the Memory Side	Description	Duration (ns)
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is  $WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1$ . For the AccessCompletion, the GPMC requires 1 cycle of data hold time (nCS deassertion).

**Table 15-266. GPMC Timing parameters for Asynchronous Single Write**

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime		n/a (asynchronous mode)		
AccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime		n/a (single access)		
WrCycleTime	$WeOffTime + AccessCompletion$	57, 615	6	WRCYCLETIME = 0x06
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	$WeOffTime + 1$	57, 615	6	CSWROFFTIME = 0x06
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	$tAVSC + tAVDP$	9	1	ADVWROFFTIME = 0x01
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	$tCS + tWP + tWPH$	48	5	WEOFFTIME = 0x05

**Figure 15-99. Asynchronous Single Write Access (Timing Parameters in Clock Cycles)**

gpmc-040

### 15.4.6.2 How to choose a suitable memory to use with the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

#### 15.4.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, OneNAND™, ...)
- 8- and 16-bit NAND flash device

**NOTE:** Non-multiplexed NOR flash devices are supported by the GPMC but their usage is highly limited. As only ten address pins are available on the GPMC interface, the maximum device size supported is 2KB.

##### 15.4.6.2.1.1 Memory Pin Multiplexing

This section highlights the interfacing differences of the GPMC supported memories.

**Table 15-267. Supported memories interfaces**

Function	16-bit Address/Data muxed pSRAM or NOR Flash <sup>(1)</sup>	OneNAND	16-bit NAND	8-bit NAND

#### 15.4.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device, that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Thanks to its high density NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. NAND non-volatility, makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 15-268 summarizes the NAND interface signals level applied to external device or memories.

**Table 15-268. NAND Interface Bus Operations Summary**

Bus operation	CLE	ALE	nCE	nWE <sup>(1)</sup>	nRE <sup>(1)</sup>	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H <sup>(2)</sup>	H <sup>(2)</sup>	H <sup>(2)</sup>	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Stand-by	x	x	H	x	x	H/L <sup>(3)</sup>

<sup>(1)</sup> RE stands for rising edge, FE stands for falling edge

<sup>(2)</sup> Can be either nCE high, or WE and nRE high.

<sup>(3)</sup> nWP should be biased to CMOS high or CMOS low for standby

### 15.4.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND which is a sequential access device, NOR is directly addressable, that is, is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities it has slow write and erase functions compared to NAND architecture.

Table 15-269 summarizes the NOR interface signals level applied to external device or memories.

**Table 15-269. NOR Interface Bus Operations Summary**

Bus operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

### 15.4.6.2.1.4 Other Technologies

Other supported device type interact with the GPMC through the NOR interface protocol.

OneNAND™ is a high density and low-power memory device. OneNAND™ is based on single- or multi-level-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR Flash, plus has synchronous write capability. It reads faster than conventional NAND and write faster than conventional NOR flash. Hence, it is appropriate for both mass storage and code storage.

pSRAM stands for pseudo-static random access memory. pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR Flash, plus has synchronous write capability.

### 15.4.6.2.1.5 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4-8-16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4-8-16 Word16)
- Synchronous read burst access with wrap capability (4-8-16 Word16)

### 15.4.6.2.2 GPMC Features and Settings

This section lists GPMC features and settings:

- Supported device type: up to four NAND or NOR protocol external memories or devices
- Operating Voltage: 1.8V;
- Maximum GPMC addressing capability: 1 GByte divided into eight chip-selects
- Maximum supported memory size: 256 MBytes (must be a power-of-2)
- Minimum supported memory size: 16 MBytes (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping
- Supports bus turn around

## 15.4.7 GPMC Register Manual

This section provides information about the GPMC instance in this product. [Table 15-271](#) provides a summary of the GPMC registers. The remaining parts of this section describe the registers within the module instance.

### 15.4.7.1 GPMC Register Summary

**Table 15-270. GPMC Instance Summary**

Module Name	Base Address	Size
GPMC	0x5000 0000	32 Mbytes

**Table 15-271. GPMC Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	GPMC L3 Physical Address

### 15.4.7.2 GPMC Register Descriptions

**NOTE:** All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to [GPMC\\_NAND\\_DATA\\_i](#) register, are little endian. If the [GPMC\\_NAND\\_DATA\\_i](#) register location is accessed, the endianness is access-dependent.

In the whole section *i* corresponds to the chip-select number, *i* = 0 to 3.

**Table 15-272. GPMC\_REVISION**

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	GPMC
<b>Physical Address</b>	0x5000 0000		
<b>Description</b>	This register contains the IP revision code.		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP revision	R	T1 internal data

**Table 15-274. GPMC\_SYSCONFIG**

<b>Address Offset</b>	0x0000 0010	<b>Instance</b>	GPMC
<b>Physical Address</b>	0x5000 0010		
<b>Description</b>	This register controls the various parameters of the Interconnect.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												SIDLEMODE	RESERVED	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Write 0s for future compatibility. Reads return 0s.	RW	0x00000000
4:3	SIDLEMODE	0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module 0x3: Do not use	RW	0x0
2	RESERVED	Write 0 for future compatibility Reads returns 0	RW	0x0
1	SOFTRESET	Software reset. Set this bit to 1 triggers a module reset. This bit is automatically reset by hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset	RW	0x0

Bits	Field Name	Description	Type	Reset
0	AUTOIDLE	Internal Interface clock gating strategy 0x0: Interface clock is free-running 0x1: Automatic Interface clock gating strategy is applied, based on the Interconnect activity	RW	0x0

## 15.5 Error Location Module

### 15.5.1 Error Location Module Overview

Non-managed NAND flash memories can be dense and nonvolatile in their own nature, but error-prone. When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the central processing unit (CPU) that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

#### 15.5.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

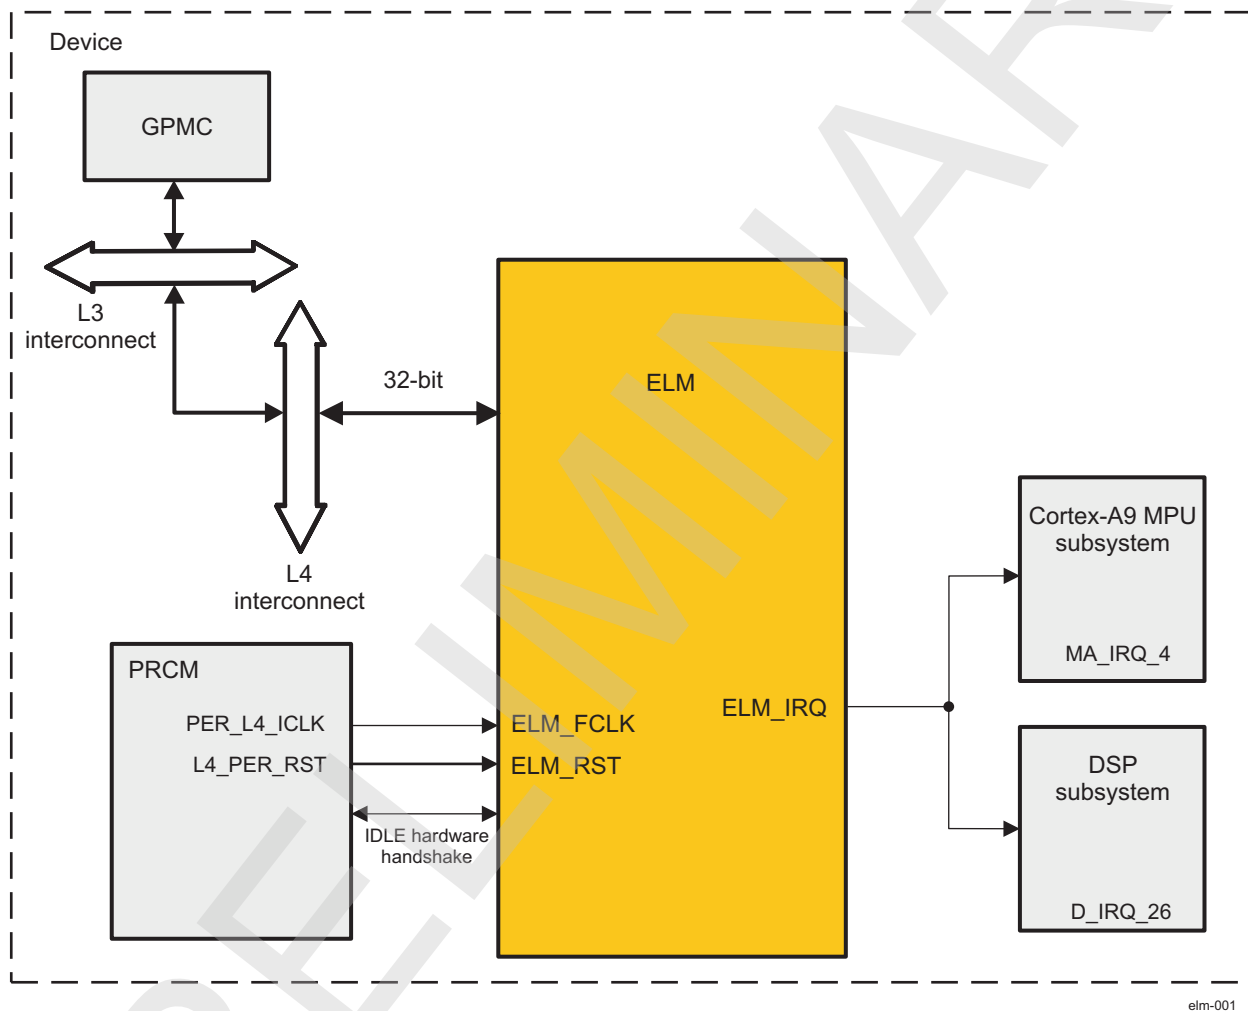

### 15.5.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. The microprocessor unit (MPU) can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 15-100 shows the integration of the ELM subsystem in the device.

**Figure 15-100. ELM Integration**

**Table 15-344. Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
ELM	PD_L4_PER	No	NA

**Table 15-345. Clocks and Resets**

Clocks

Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
ELM	ELM_RST	L4_PER_RST	PRCM	Power domain hardware reset For information about PRCM reset sources and distribution, see <a href="#">Section 3.5.4, Reset Domains</a> in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .

**Table 15-346. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
ELM	ELM_IRQ	MA_IRQ_4	Cortex-A9	BCH error-location module interrupt For information about Cortex-A9 interrupt control, see <a href="#">Section 17.3.2, Interrupt Requests to Cortex-A9 MPU INTC</a> .
		D_IRQ_26	DSP	BCH error-location module interrupt For information about DSP interrupt control, see <a href="#">Interrupts Requests</a> .

**15.5.3 ELM Functional Description**

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

**15.5.3.1 ELM Software Reset**

To perform a software reset, write a 1 to the [ELM\\_SYSCONFIG\[1\] SOFTRESET](#) bit. The [ELM\\_SYSSTATUS\[0\] RESETDONE](#) bit indicates that the software reset is complete when its value is 1. When the software reset completes, the [ELM\\_SYSCONFIG\[1\] SOFTRESET](#) bit is automatically reset.

**15.5.3.2 ELM Power Management**

[Table 15-347](#) describes the power-management features available to the ELM module.

**NOTE:**

- For information about source clock gating and sleep/wake-up transitions description, see the [Section 3.6.8, CD\\_L4\\_PER Clock Domain](#) in [Chapter 3, Power, Reset, and Clock Management](#).
- For a general description of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see the [Section 3.6 Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#)

**Table 15-347. Local Power Management Features**

Feature	Registers	Description
Clock autogating	<a href="#">ELM_SYSCONFIG</a> [0] AUTOGATING bit	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	<a href="#">ELM_SYSCONFIG</a> [4:3] SIDLEMODE bit field	Force-idle, No-idle, and Smart-idle modes are available.
Clock activity	<a href="#">ELM_SYSCONFIG</a> [8] CLOCKACTIVITY bit	The clock can be switched-off or maintained during the wake-up period.
Master Standby modes	N/A	
Global Wake-up Enable	N/A	
Wake-up Sources Enable	N/A	

**CAUTION**

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits. For a description of the ClockActivity feature, see [Chapter 3, Power, Reset, and Clock Management](#).

**15.5.3.3 ELM Interrupt Requests**

[Table 15-348](#) lists the event flags, and their masks, that can cause module interrupts.

**Table 15-348. Events**

Event Flag	Event Mask	Map to	Description
<a href="#">ELM_IRQSTATUS</a> [8] PAGE_VALID	<a href="#">ELM_IRQENABLE</a> [8] PAGE_MASK	ELM_IRQ	Page interrupt
<a href="#">ELM_IRQSTATUS</a> [7] LOC_VALID_7	<a href="#">ELM_IRQENABLE</a> [7] LOCATION_MASK_7	ELM_IRQ	Error-location interrupt for syndrome polynomial 7
<a href="#">ELM_IRQSTATUS</a> [6] LOC_VALID_6	<a href="#">ELM_IRQENABLE</a> [6] LOCATION_MASK_6	ELM_IRQ	Error-location interrupt for syndrome polynomial 6
<a href="#">ELM_IRQSTATUS</a> [5] LOC_VALID_5	<a href="#">ELM_IRQENABLE</a> [5] LOCATION_MASK_5	ELM_IRQ	Error-location interrupt for syndrome polynomial 5
<a href="#">ELM_IRQSTATUS</a> [4] LOC_VALID_4	<a href="#">ELM_IRQENABLE</a> [4] LOCATION_MASK_4	ELM_IRQ	Error-location interrupt for syndrome polynomial 4
<a href="#">ELM_IRQSTATUS</a> [3] LOC_VALID_3	<a href="#">ELM_IRQENABLE</a> [3] LOCATION_MASK_3	ELM_IRQ	Error-location interrupt for syndrome polynomial 3
<a href="#">ELM_IRQSTATUS</a> [2] LOC_VALID_2	<a href="#">ELM_IRQENABLE</a> [2] LOCATION_MASK_2	ELM_IRQ	Error-location interrupt for syndrome polynomial 2
<a href="#">ELM_IRQSTATUS</a> [1] LOC_VALID_1	<a href="#">ELM_IRQENABLE</a> [1] LOCATION_MASK_1	ELM_IRQ	Error-location interrupt for syndrome polynomial 1
<a href="#">ELM_IRQSTATUS</a> [0] LOC_VALID_0	<a href="#">ELM_IRQENABLE</a> [0] LOCATION_MASK_0	ELM_IRQ	Error-location interrupt for syndrome polynomial 0

**15.5.3.4 Processing Initialization**

[ELM\\_LOCATION\\_CONFIG](#) global setting parameters must be set before using the error-location engine. The [ELM\\_LOCATION\\_CONFIG](#)[1:0] ECC\_BCH\_LEVEL bit defines the error-correction level used (4-, 8-, or 16-bit error-correction). The [ELM\\_LOCATION\\_CONFIG](#)[26:16] ECC\_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

The CPU can choose to use the ELM in continuous mode or page mode. If all [ELM\\_PAGE\\_CTRL](#)[i] SECTOR\_i bits are reset (i is the syndrome polynomial number, i = 0 to 7), continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently – results for a syndrome can be retrieved and acknowledged at any time, whatever the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities – only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all `ELM_IRQENABLE[i] LOCATION_MASK_i` bits (i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the `ELM_IRQENABLE[8] PAGE_MASK` bit must be set to 1 when in page mode.

The CPU initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: `ELM_SYNDROME_FRAGMENT_0_i` to `ELM_SYNDROME_FRAGMENT_6_i`. The first six registers can be written in any order, but `ELM_SYNDROME_FRAGMENT_6_i` must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the `ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID` bit).

As soon as one validity bit is asserted (`ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x1`, with i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated `ELM_LOCATION_STATUS_i` and `ELM_ERROR_LOCATION_0_i` to `ELM_ERROR_LOCATION_15_i` registers are not reset (i = 0 to 7). The software must not consider them until the corresponding `ELM_IRQSTATUS[i] LOC_VALID_i` bit is set.

### 15.5.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the `ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE` bit is set to 1 and the `ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS` bit field is set to 0x0.
- Too many errors are detected; that is, when the `ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE` bit is set to 0 while the `ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS` bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if `ECC_CORRECTABLE` is 0.

If the engine completes early, the associated error-location registers `ELM_ERROR_LOCATION_0_i` to `ELM_ERROR_LOCATION_15_i` are not updated (i = 0 to 7).

In all other cases, the engine goes through the entire error-location process. Each time an error-location is found, it is logged in the associated `ECC_ERROR_LOCATION` bit field. The first error detected is logged in the `ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION` bit field; the second in the `ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION` bit field, and so on.

**Table 15-349. ELM\_LOCATION\_STATUS\_i Value Decoding Table**

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the <code>ELM_ERROR_LOCATION_0_i</code> to <code>ELM_ERROR_LOCATION_15_i</code> results.
0	Any	Failed	Unknown	Software-dependant

### 15.5.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its `ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID` bit is reset. It must not be set again until the exit status registers, `ELM_LOCATION_STATUS_i` (i = 0 to 7), for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding `ELM_IRQSTATUS[i] LOC_VALID_i` bit is set ( $i = 0$  to  $7$ ). The processing-exit status is available from the associated `ELM_LOCATION_STATUS_i` register, and error locations are stored in order in the `ECC_ERROR_LOCATION` fields. The software must only read valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the `ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID` validity bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in `ELM_PAGE_CTRL` are reset), an interrupt is triggered whenever a `ELM_IRQSTATUS[i] LOC_VALID_i` bit is asserted. The CPU must read the `ELM_IRQSTATUS` register to determine which polynomial is processed and retrieve the exit status and error locations (`ELM_LOCATION_STATUS_i` and `ELM_ERROR_LOCATION_0_i` to `ELM_ERROR_LOCATION_15_i`). When done, the CPU must clear the corresponding `ELM_IRQSTATUS[i] LOC_VALID_i` bit by writing it to 1. Other status bits must be written to 0 so that other interrupts are not unintentionally cleared. When using this mode, the `ELM_IRQSTATUS[8] PAGE_VALID` interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the `ELM_IRQENABLE[i] LOCATION_MASK_i` bits are cleared. A page is defined using the `ELM_PAGE_CTRL` register. Each `SECTOR_i` bit set means the corresponding polynomial  $i$  is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the `ELM_IRQSTATUS[i] LOC_VALID_i` bit fields. The module triggers an `ELM_IRQSTATUS[8] PAGE_VALID` interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the `ELM_IRQSTATUS` register must be cleared by using a single atomic-write access.

---

**NOTE:** Do not modify page setting parameters in the `ELM_PAGE_CTRL` register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

---

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the `ELM_PAGE_CTRL[i] SECTOR_i` bit fields ( $i = 0$  to  $7$ ) are processed as usual, but are essentially ignored. The CPU must manually poll the `ELM_IRQSTATUS` bits to check for their status.

## 15.5.4 ELM Basic Programming Model

### 15.5.4.1 ELM Low Level Programming Model

#### 15.5.4.1.1 Processing Initialization

**Table 15-350. ELM Processing Initialization**

Sets the ELM in continuous mode or page mode	<code>ELM_PAGE_CTRL</code>	Set value
<b>If</b> continuous mode is used	All <code>ELM_PAGE_CTRL[i] SECTOR_i</code> ( $i = 0$ to $7$ )	0x0
Enables interrupt for syndrome polynomial $i$	<code>ELM_IRQENABLE[i] LOCATION_MASK_i</code>	0x1
<b>else</b> (page mode is used)	One syndrome polynomial $i$ is set <code>ELM_PAGE_CTRL[i] SECTOR_i</code> ( $i = 0$ to $7$ )	0x1
Disable all interrupts for syndrome polynomial and enable <code>PAGE_MASK</code> interrupt.	All <code>ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0</code> and <code>ELM_IRQENABLE[8] PAGE_MASK = 0x1</code>	Set value
<b>endif</b>		Set value

**Table 15-350. ELM Processing Initialization (continued)**

Step	Register/ Bit Field / Programming Model	Value
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value
	ELM_SYNDROME_FRAGMENT_1_i	Set value
	ELM_SYNDROME_FRAGMENT_5_i	Set value
	ELM_SYNDROME_FRAGMENT_6_i	Set value
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

**15.5.4.1.2 Read Results**

The engine goes through the entire error-location process and results can be read. [Table 15-351](#) and [Table 15-352](#) describe the processing completion for continuous and page modes, respectively.

**Table 15-351. ELM Processing Completion for Continuous Mode**

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1
<b>if</b> the process fails (too many errors) It is software dependant.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
<b>else</b> (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. It is the software responsibility to correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
<b>endif</b>		
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing ([ELM\\_SYNDROME\\_FRAGMENT\\_6\\_i\[16\]](#) SYNDROME\_VALID = 0x0) and after the exit status register check ([ELM\\_LOCATION\\_STATUS\\_i](#)).

**Table 15-352. ELM Processing Completion for Page Mode**

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
<b>Repeat</b> the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
<b>if</b> the process fails (too many errors) It is software dependant.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
<b>else</b> (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	

**Table 15-352. ELM Processing Completion for Page Mode (continued)**

Step	Register/ Bit Field / Programming Model	Value
Read the error-location bit addresses for syndrome polynomial <i>i</i> of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_ <i>i</i> [12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_ <i>i</i> [12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_ <i>i</i> [12:0] ECC_ERROR_LOCATION	
<b>endif</b>		
<b>End Repeat</b>		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM\_IRQSTATUS[*i*] LOC\_VALID\_*i* = 0x1 for all syndrome polynomials *i* used in the page).

#### 15.5.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM module is programmed for an 8-bit error-correction capability in continuous mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a non-zero polynomial syndrome is reported from the GPMC (Polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

**Table 15-353. Use Case: Continuous Mode**

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 8 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x1
Defines the maximum buffer length: 528 bytes (2x528 = 1056)	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in continuous mode	ELM_PAGE_CTRL	0
Enables interrupt for syndrome polynomial 0	ELM_IRQENABLE[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_ <i>i</i> (i=0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_ <i>i</i> (i=0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_ <i>i</i> (i=0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_ <i>i</i> (i=0)	0x0000000A
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_ <i>i</i> [16] SYNDROME_VALID (i=0)	0x1
Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_ <i>i</i> [8] ECC_CORRECTABLE (i=0)	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_ <i>i</i> [4:0] ECC_NB_ERRORS (i=0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the 4 first registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_ <i>i</i> (i=0)	0x1AF
	ELM_ERROR_LOCATION_1_ <i>i</i> (i=0)	0x426
	ELM_ERROR_LOCATION_2_ <i>i</i> (i=0)	0x775
	ELM_ERROR_LOCATION_3_ <i>i</i> (i=0)	0xD7C

**Table 15-353. Use Case: Continuous Mode (continued)**

Step	Register/ Bit Field / Programming Model	Value
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in Table 15-354 are given in decimal format.

**Table 15-354. 16-bit NAND Sector Buffer Address Map**

NAND Memory Address	Message bit addresses in the memory word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	4215	4214	4213	4212	4211	4210	4209	4208	4223	4222	4221	4220	4219	4218	4217	4216
1	4175	4174	4173	4172	4171	4170	4169	4168	4183	4182	4181	4180	4179	4178	4177	4176

50	3415	3414	3413	3412	3411	3410	3409	3408	3423	3422	3421	3420	3419	3418	3417	3416
...																
255	135	134	133	132	131	130	129	128	143	142	141	140	139	138	137	136
256	119	118	117	116	115	114	113	112	127	126	125	124	123	122	121	120
257	103	102	101	100	99	98	97	96	111	110	109	108	107	106	105	104
258	87	86	85	84	83	82	81	80	95	94	93	92	91	90	89	88
259	71	70	69	68	67	66	65	64	79	78	77	76	75	74	73	72
260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and to flip this bit. The same process must be repeated for all detected errors.

**15.5.4.3 Use Case: ELM Used in Page Mode**

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (Polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

**Table 15-355. Use Case: Page Mode**

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1

<b>Address Offset</b>	0x0000 0010	
<b>Physical Address</b>	See <a href="#">Table 15-357</a> .	<b>Instance</b> ELM
<b>Description</b>	This register allows controlling various parameters of the OCP interface.	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CLOCKACTIVITYOCP	RESERVED		SIDLEMODE		RESERVED	SOFTRESET	AUTOGATING								

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	R	0x000000
8	CLOCKACTIVITYOCP	OCP Clock activity when module is in IDLE mode (during wake up mode period) 0x0: OCP Clock can be switch-off 0x1: OCP Clock is maintained during wake up period	RW	0
7:5	RESERVED	Reserved	R	0x0
4:3	SIDLEMODE	Slave interface power management (IDLE req/ack control) 0x0: FORCE Idle. IDLE request is acknowledged unconditionally and immediately (Default <i>Dumb</i> mode for safety) 0x1: NO idle. IDLE request is never acknowledged. 0x2: SMART Idle. The acknowledgment to an IDLE request is given based on the internal activity. 0x3: Reserved - do not use	RW	0x2
2	RESERVED	Reserved	R	0
1	SOFTRESET	Module software reset This bit is automatically reset by hardware (During reads, it always returns 0.) It has same effect as the OCP hardware reset. 0x0: Normal mode 0x1: Start soft reset sequence.	RW	0
0	AUTOGATING	Internal OCP clock gating strategy (no module visible impact other than saving power) 0x0: OCP clock is free-running 0x1: Automatic internal OCP clock gating strategy is applied based on the OCP interface activity.	RW	1

PRELIMINARY

## 15.6 On-Chip Memory (OCM) Subsystem

### 15.6.1 OCM Subsystem Overview

There are three on-chip memories in the device.

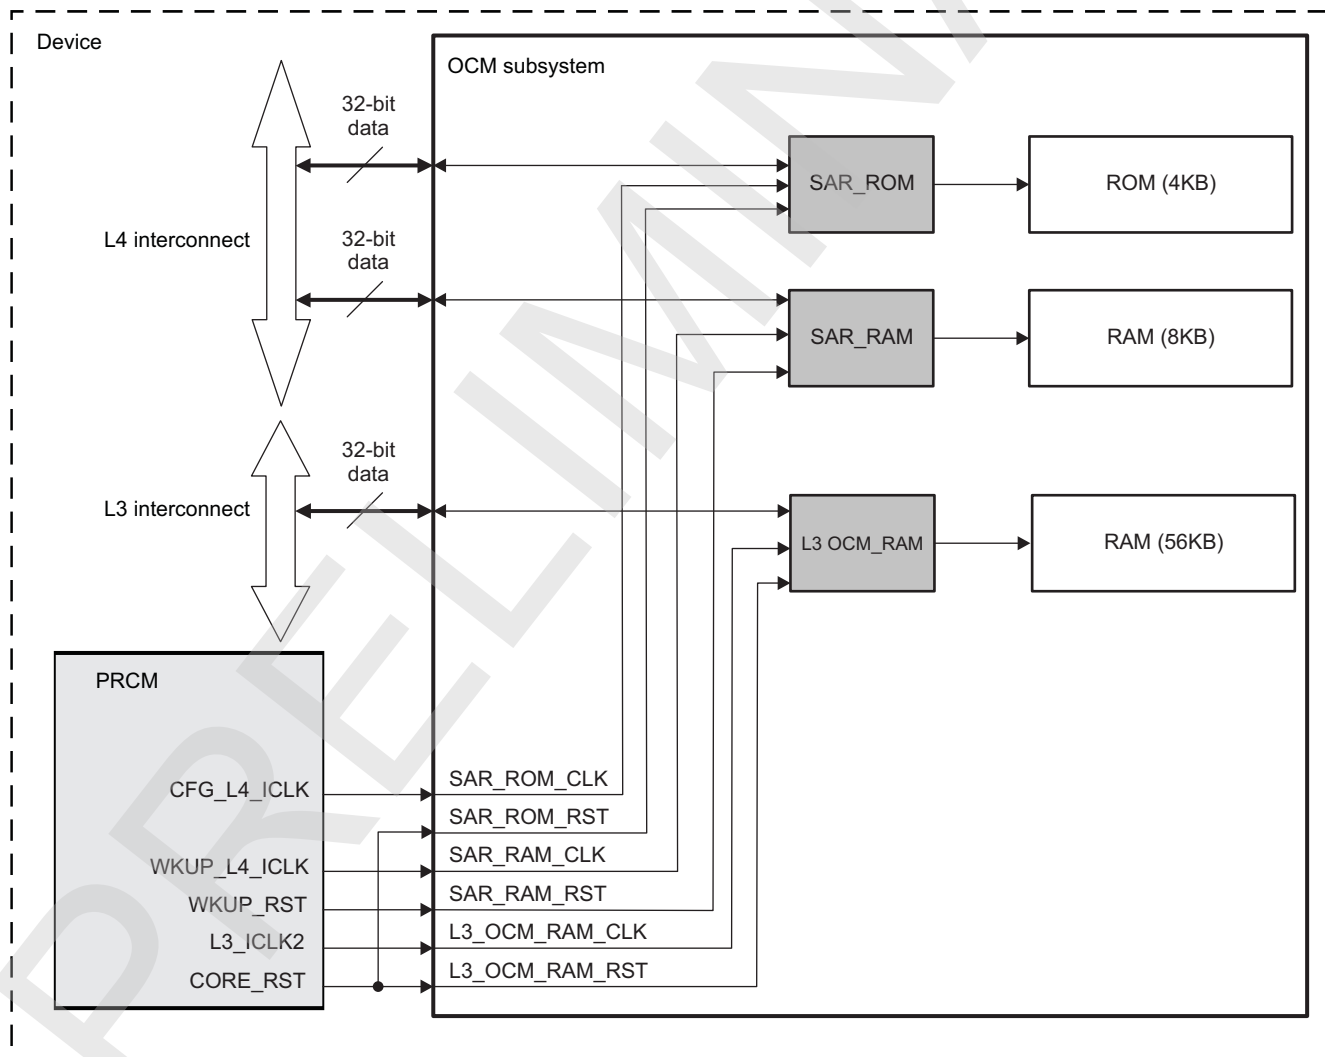

- A 4K-byte SAR read-only memory (ROM)
- A 8K-byte SAR random-access memory (RAM)
- A 56K-byte L3 static random-access memory (L3 OCM\_RAM)

There are other on-chip memories located inside other subsystems (Cortex-A9 MPU, DSP IVA-HD, ABE, Cortex-M3 MPU) that are not described in the following sections. Refer to each subsystem chapter for more details.

### 15.6.2 OCM Subsystem Integration

Figure 15-101 shows the integration of the OCM subsystem to the device.

**Figure 15-101. OCM Subsystem Integration to the Device**

Ocm-004

Table 15-420 through Table 15-421 summarize the integration of the module in the device.

### 15.6.3 OCM Subsystem Functional Description

#### 15.6.3.1 SAR ROM

This on-chip ROM contains 4K bytes of memory and a linked list of descriptors used by the system DMA (sDMA) during the restore context operation (when device transitions from OFF to ON modes).

The device-embedded SAR ROM has the following characteristics:

- 4K-bytes ROM
- 32-bit access per cycle
- Support for single and burst access transactions

The memory space of the embedded ROM starts at 0x4A05 E000 and ends at 0x4A05 FFFF (8K bytes are reserved, but only 4K bytes are used).

### 15.6.3.2 SAR RAM

The on-chip SAR RAM contains 8K bytes and is mapped as 4 blocks with irregular region sizes. This memory content is preserved when the device goes into OFF mode (as long as the wake-up voltage domain remains supplied). It is used as context-saving memory to be written by the software, so that the sDMA restores its saved content when the device transitions from OFF to ON mode. Locations not used by the sDMA can be used as a scratch-pad memory by the software. It is mapped on the wake-up voltage domain.

The device-embedded SAR RAM has the following characteristics:

- Support for single-access transactions
  - Operates at full L4-PER interconnect clock frequency
  - 32-bit access per cycle

The SAR RAM space is at the following location:

- SAR space 1 (4KB): Starts at 0x4A32 6000 and ends at 0x4A32 6FFF
- SAR space 2 (1KB): Starts at 0x4A32 7000 and ends at 0x4A32 73FF
- SAR space 3 (2KB): Starts at 0x4A32 8000 and ends at 0x4A32 87FF
- SAR space 4 (1KB): Starts at 0x4A32 9000 and ends at 0x4A32 93FF

### 15.6.3.3 L3 OCM\_RAM

The on-chip L3 OCM\_RAM contains 56K bytes of RAM, partitioning is defined by the L3 firewall logic.

The device-embedded L3 OCM\_RAM has the following characteristics:

- Support for single and burst access transactions:
  - Operates at full L3 interconnect clock frequency
  - Fully pipelined, one 32-bit access per cycle
- Restricted access support based on:
  - A region-based partitioning (refer to L3 firewall description)
  - The module owner of the access, with respect to its read and write permissions to that region
  - The transaction attributes of the access, with respect to the region permission properties. See [Section 13.2, L3 Interconnect](#) for details.

The memory space of the embedded RAM starts at 0x4030 0000 and ends at 0x4030 DFFF.

This chapter describes the system direct memory access (sDMA) module.

## 16.1 sDMA Module Overview

The system direct memory access (sDMA), also called DMA4, performs high-performance data transfers between memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The DMA controller includes the following main features:

- Data transfer support in either direction between:
  - Memory and memory
  - Memory and peripheral device
- 32 logical DMA channels supporting:
  - Multiple concurrent transfers
  - Independent transfer profile for each channel
  - 8-bit, 16-bit, or 32-bit data element transfer size
  - Software-triggered or hardware-synchronized transfers
  - Flexible source and destination address generation
  - Burst read and write
  - Chained multiple-channel transfers
  - Endianism conversion
  - Draining
  - Linked-list support for descriptor types 1, 2, and 3
- First-come, first-serve DMA scheduling with fixed priority
- Up to 127 DMA requests
- Constant fill
- Transparent copy
- Four programmable interrupt request output lines
- FIFO depth: 256 x 64-bit
- Data buffering
- FIFO budget allocation
- Power-management support
- Auto-idle power-saving support
- Implementation of retention flip-flops (RFFs) to support dynamic power switching (DPS) between system power modes without MPU involvement. For more information about DPS, see [Section 3.1.2.3, Dynamic Power Switching \(DPS\)](#).

Figure 16-1 shows an overview of the sDMA module.

Figure 16-1. sDMA Overview

The sDMA module has three ports: one read, one write, and one configuration port and provides multiple logical channel support. A dynamically allocated FIFO queue memory pool provides buffering between the read and write ports, which are multithreaded (two threads for the write port and four threads for the read port); this means that each transaction is flagged by a thread ID (0, 1, 2, or 3) in the request direction and in the response direction. This allows the read port to have four outstanding requests at a time. The write port has two threads budget available.

The MPU (or DSP) configures the sDMA through the L4-CFG interconnect.

## 16.2 sDMA Controller Environment

The sDMA controller supports external DMA requests through the sys\_ndmareq[3:0] pins (see [Table 16-1](#)). A logical channel can be configured to respond to an external synchronization request.

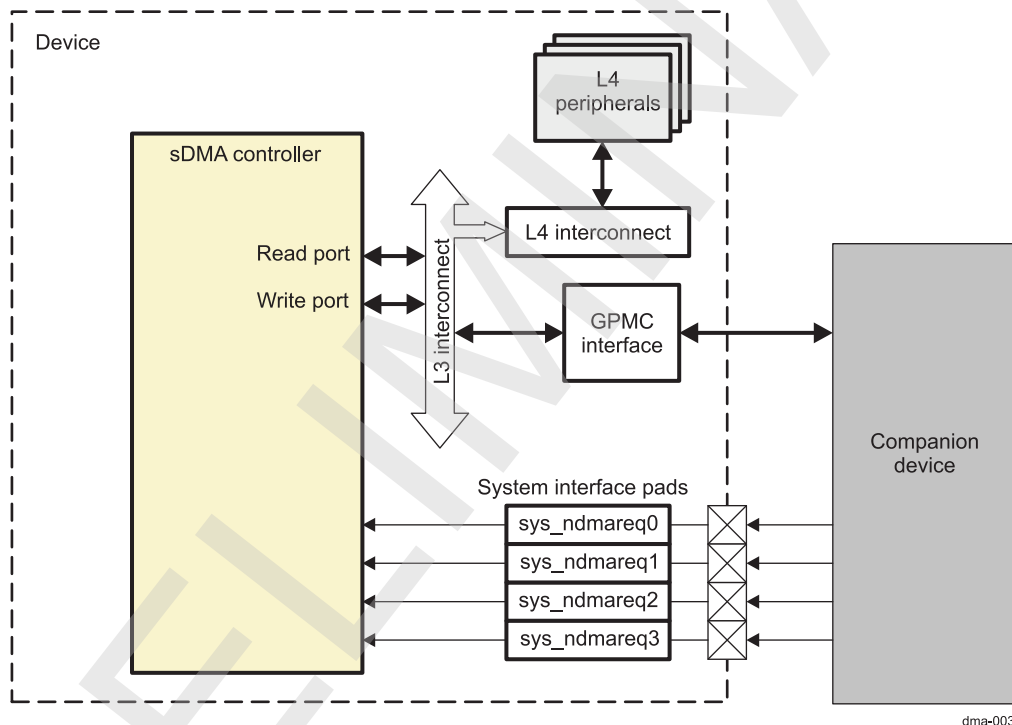

**Table 16-1. External sDMA Request Signals**

Signal Name	I/O <sup>(1)</sup>	Description
sys_ndmareq0	I	External DMA request 0 (system expansion)
sys_ndmareq1	I	External DMA request 1 (system expansion)
sys_ndmareq2	I	External DMA request 2 (system expansion)
sys_ndmareq3	I	External DMA request 3 (system expansion)

<sup>(1)</sup> I = Input, O = Output

[Figure 16-2](#) shows an example of how to use the external hardware DMA request pins in the sDMA environment.

**Figure 16-2. Example of External DMA Requests Use**

dma-003

An external device can use the external DMA request pins to start a logical channel transfer over the general-purpose memory controller (GPMC) interface. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the four signal lines to pins, see [Chapter 18, Control Module](#).

The external hardware DMA request line schemes can be either edge-sensitive or transition-sensitive. The default scheme for external requests is transition-sensitive. The sensitivity selection can be configured in the control module. For more information, see [Chapter 18, Control Module](#).

All internal peripherals of the device use the transition-sensitive scheme.

[Figure 16-3](#) shows the DMA request captured on a falling edge in the edge-sensitive scheme.

**Figure 16-3. Edge-Sensitive DMA Request Scheme**

dma-013

For a transition-sensitive DMA request (see [Figure 16-4](#)), the line must be maintained low (asserted) until the first DMA access is complete, after which the line must be maintained high (deasserted) for greater than one clock cycle (DMA\_L3\_ICLK):

- When the deassertion time is less than one clock cycle, the sDMA might not detect the deassertion.
- When the channel is enabled one cycle after a DMA request is disabled, the channel detects the DMA request and starts the corresponding transfer.
- When the channel is enabled two cycles after the DMA request is disabled, the channel does not detect the DMA request.

**Figure 16-4. Transition-Sensitive DMA Request Scheme**

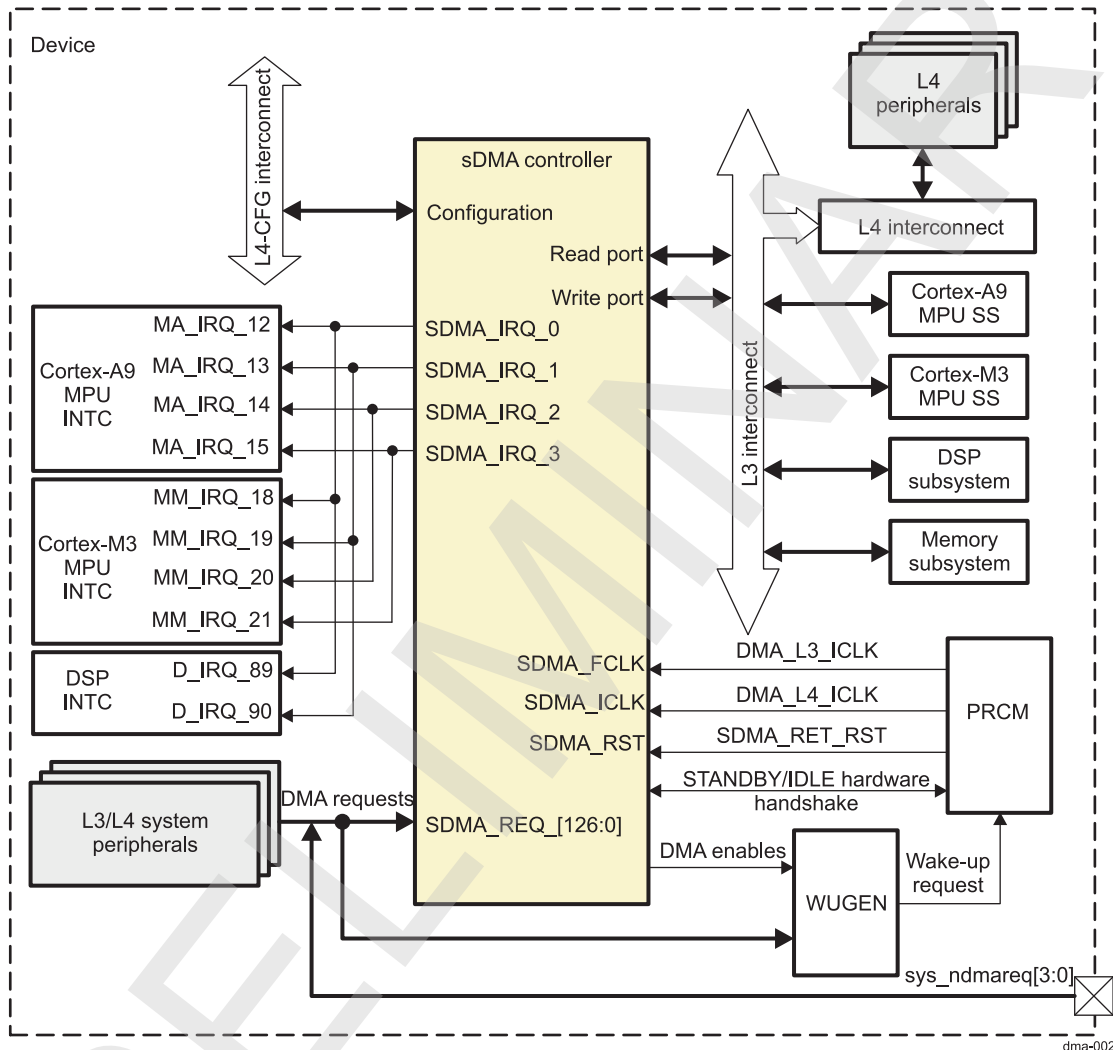

dma-012

## 16.3 sDMA Module Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 16-5 shows the sDMA controller integration.

**Figure 16-5. sDMA Controller Integration**

**NOTE:** For more information about the wake-up generator (WUGEN), the STANDBY/IDLE hardware handshake, and the wake-up request, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 16-2 through Table 16-4 summarize the integration of the module in the device.

**Table 16-2. Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
sDMA	PD_CORE	L3 and L4-CFG

**Table 16-3. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
sDMA	SDMA_FCLK	DMA_L3_ICLK	PRCM	It is both a functional clock for all internal logic and for the two master read and write ports. For information about PRCM clock gating and management, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
sDMA	SDMA_ICLK	DMA_L4_ICLK	PRCM	Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
sDMA	SDMA_RST	SDMA_RET_RST	PRCM	Hardware reset. It initializes all internal logic of the sDMA module, all global registers and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .

**Table 16-4. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
sDMA	SDMA_IRQ_0	MA_IRQ_12	Cortex-A9 MPU INTC	sDMA interrupt request 0. For information about the Cortex-A9 MPU INTC, see <a href="#">Section 17.3.2</a> .
	SDMA_IRQ_1	MA_IRQ_13	Cortex-A9 MPU INTC	sDMA interrupt request 1
	SDMA_IRQ_2	MA_IRQ_14	Cortex-A9 MPU INTC	sDMA interrupt request 2
	SDMA_IRQ_3	MA_IRQ_15	Cortex-A9 MPU INTC	sDMA interrupt request 3
sDMA	SDMA_IRQ_0	MM_IRQ_18	Cortex-M3 MPU INTC	sDMA interrupt request 0. For information about the Cortex-M3 MPU INTC, see <a href="#">Section 17.3.3</a> .
	SDMA_IRQ_1	MM_IRQ_19	Cortex-M3 MPU INTC	sDMA interrupt request 1
	SDMA_IRQ_2	MM_IRQ_20	Cortex-M3 MPU INTC	sDMA interrupt request 2
	SDMA_IRQ_3	MM_IRQ_21	Cortex-M3 MPU INTC	sDMA interrupt request 3
sDMA	SDMA_IRQ_0	D_IRQ_89	DSP INTC	sDMA interrupt request 0. For information about the DSP INTC, see .
	SDMA_IRQ_1	D_IRQ_90	DSP INTC	sDMA interrupt request 1

**NOTE:** For a description of the interrupt source, see [Section 16.4.2, sDMA Controller Interrupt Requests](#).

### 16.3.1 DMA Requests to the sDMA Controller

Table 16-5 lists the sDMA controller request mapping.

**Table 16-5. sDMA Controller Request Mapping**

DMA Request Line	Source	Description
S_DMA_0	Reserved	Reserved
S_DMA_1	sys_dma_req0	External DMA request 0 (system expansion)
S_DMA_2	sys_dma_req1	External DMA request 1 (system expansion)
S_DMA_3	GPMC_DMA	GPMC data transmit request from prefetch engine
S_DMA_4	Reserved	Reserved
S_DMA_5	DSS_DISPC_DMA	Frame update request
S_DMA_6	sys_dma_req2	External DMA request 2 (system expansion)
S_DMA_7	MCASP1_AXEVT	McASP1 transmit request
S_DMA_8	ISS_DMA0	Imaging subsystem request 0
S_DMA_9	ISS_DMA1	Imaging subsystem request 1
S_DMA_10	Reserved	Reserved
S_DMA_11	ISS_DMA2	Imaging subsystem request 2
S_DMA_12	ISS_DMA3	Imaging subsystem request 3
S_DMA_13	DSS_RFBI_DMA	Display subsystem RFBI request

## 16.4 sDMA Functional Description

The sDMA module provides high-performance data transfers between memories and peripheral devices with low processor use. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

Figure 16-6 shows the sDMA controller top-level block diagram.

Figure 16-6. sDMA Controller Top-Level Block Diagram

dma-005

### 16.4.1 sDMA Controller Power Management

Table 16-6 describes power-management features available for the sDMA controller.

**NOTE:**

- For information about source clock gating and sleep/wake-up transitions, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For a description of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**Table 16-6. Local Power Management Features**

Feature	Registers	Description
Clock auto gating	<a href="#">DMA4_OCP_SYSCONFIG</a> [0] AUTOIDLE bit	This bit allows local power optimization inside the module by gating the SDMA_ICLK clock upon the interface activity.
Slave idle modes	<a href="#">DMA4_OCP_SYSCONFIG</a> [4:3] SIDLEMODE bit field	Force-idle, no-idle and smart-idle modes are available.
Clock activity	<a href="#">DMA4_OCP_SYSCONFIG</a> [9:8] CLOCKACTIVITY bit field	For configuration details, see <a href="#">Table 16-7</a> .
Master standby modes	<a href="#">DMA4_OCP_SYSCONFIG</a> [13:12] MIDLEMODE bit field	Force-standby, no-standby and smart-standby modes are available.
Global Wake-up Enable	N/A	Feature not available
Wake-up Sources Enable	N/A	Feature not available

**Table 16-7. Clock Activity Settings**

SDMA_CLOCKACTIVITY Values	Clock State When Module is in IDLE State	
	SDMA_ICLK	SDMA_FCLK
00	Off	Off
10	Off	On
01	On	Off
11	On	On

**CAUTION**

Because the PRCM module cannot read CLOCKACTIVITY settings through hardware, software must ensure consistent programming between the SDMA\_CLOCKACTIVITY and sDMA clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**16.4.2 sDMA Controller Interrupt Requests**

DMA4 has four interrupt lines ( $L_j$ , where  $j = 0, 1, 2, 3$ ). Each logical channel can request an interrupt over any line. The attachment of a channel interrupt event to one of these four external lines is programmable. Software determines whether it attaches a channel interrupt to a single IRQ line or to multiple IRQ lines.

There are two different registers per interrupt line:

- The [DMA4\\_IRQSTATUS\\_Lj](#) CH\_31\_0\_Lj field shows the status of the different sources of interrupt. If the [DMA4\\_IRQENABLE\\_Lj](#) bit is 1, channel  $i$  is the source of interrupt in line  $j$ . In contrast to the [DMA4\\_CSRi](#) registers, the [DMA4\\_IRQSTATUS\\_Lj](#) registers are updated regardless of the corresponding bits in the [DMA4\\_IRQENABLE\\_Lj](#) registers.
- The [DMA4\\_IRQENABLE\\_Lj](#) CH\_31\_0\_Lj\_EN field masks/unmasks the channel interrupt. If the [DMA4\\_IRQENABLE\\_Lj](#) bit is set to 0, channel interrupt  $i$  of the line  $j$  is masked.

Each logical channel can generate a number of different interrupt events when enabled (that is, set to 1) in the [DMA4\\_CICRi](#) register. Each status bit is updated in the [DMA4\\_CSRi](#) register only when the corresponding enable bit is enabled in the [DMA4\\_CICRi](#) register.

To determine an interrupt source when an interrupt rises on an interrupt line  $L_j$ :

- Identify the channel ( $LCH_i$ ) generating the interrupt.  
Read the [DMA4\\_IRQSTATUS\\_Lj.LCHi](#) ( $LCH_0$  to  $LCH_{31}$ ). If  $LCH_i = 1$ , channel  $i$  is the originator of the interrupt.
- Identify the interrupt event.  
Read the  $LCH_i$  [DMA4\\_CSRi](#). For example, if the drop event (the [DMA4\\_CSRi\[1\]](#) DROP bit) is 1, there will be a request collision.

The interrupt event status bit in the [DMA4\\_CSRi](#) register is immediately reset after it is written to 1. The interrupt status bit in the [DMA4\\_IRQSTATUS\\_Lj](#) register is cleared after it is written to 1.

### 16.4.2.1 Interrupt Generation

The sDMA module has four interrupt request output lines, SDMA\_IRQ\_0 to SDMA\_IRQ\_3. One or more logical channels can be programmed to generate an interrupt request on any of these lines when any one of the maskable DMA events listed in [Table 16-8](#) occurs.

**Table 16-8. Logical DMA Channel Events**

Event	Description
End of packet	A packet transfer completed.
End of block	A block transfer completed.
End of frame	A frame transfer completed.
End of super block	A super block transfer completed.
Half of frame	Half of the current frame transferred.
Start of last frame	The first element of the last frame transferred.
Transaction error	A transaction error is returned by the interconnect in either the read or write port.
Address error	An attempt was made to perform a DMA access to an address not aligned on an ES boundary. Condition to occur: if DMA4_CEN[23:0] CHANNEL_ELMNT_NBR = 0x000000 or DMA4_CFN[15:0] CHANNEL_FRAME_NBR = 0x0000 or DMA4_CSDP[1:0] DATA_TYPE = 0x3.
Supervisor transaction error	An error occurred, for example, when an unauthorized initiator (that is not a supervisor ) tries to use a supervisor transfer.
Drain end	Drain is completed ( <a href="#">DMA4_CCRi</a> [10] WR_ACTIVE becomes 0).
Drop error	A drop event interrupt is generated when a DMA request is being serviced while a second one is asserted and a third one arrives before the second DMA request is serviced.

The logical DMA channels that generate an interrupt on a particular IRQ output are specified through the [DMA4\\_IRQENABLE\\_Lj](#) register (where *j* is the IRQ number: 0, 1, 2, or 3). The events that generate an interrupt for a particular channel can be configured through the channel [DMA4\\_CICRi](#) register.

When an interrupt is detected, the logical DMA channel generating the event can first be identified by reading the [DMA4\\_IRQSTATUS\\_Lj](#) register. The event causing the interrupt then can be identified by reading the interrupt status via the relevant DMA channel [DMA4\\_CSRi](#) register.

### 16.4.3 Logical Channel Transfer Overview

As [Figure 16-6](#) shows, the sDMA module has one read port and one write port operating independently of each other. Buffering is provided between the read and write ports through a FIFO queue memory pool that is shared dynamically between the active logical channels.

- Logical channel synchronization
  - A logical channel is described as hardware-synchronized when the DMA transfers are triggered by DMA requests from a hardware device. Alternatively, a logical channel is described as nonsynchronized when the DMA transfer is triggered by software.
- Logical channel activation
  - A logical channel becomes active as follows:
    - For hardware-synchronized transfers, when the logical channel is enabled and the hardware DMA request line is asserted
    - For software-triggered (nonsynchronized) transfers, as soon as software enables the logical channel
- Logical channel transfer composition
  - A DMA transfer is divided automatically into a number of transactions. Depending on the logical channel context configured, the transfer size, the start address alignment, the addressing mode, and the configured maximum burst size, each transaction can be either a single access or a burst of accesses.
- Logical channel scheduling

When several logical channels are active at the same time, schedulers manage the read and write ports. The scheduling of logical channel transfers is similar for both read and write ports. When a logical channel becomes active, it is added to the tail of a scheduling queue. If more than one logical channel becomes active at the same time, the one with the lower number is queued first. This mechanism provides a first-come, first-serve scheduling scheme between the concurrently active logical channels.

In addition, each read and write port has a high-priority queue and a low-priority queue. The priority bits (WRITE\_PRIORITY and READ\_PRIORITY) in the logical channel DMA4\_CCRi register determine if a logical channel is queued as high or low priority. A software-configurable 8-bit priority counter gives weighting to the priority write queue. For every N (1 to 255) schedules from the priority write queue, one is scheduled from the regular write queue. A channel that is scheduled goes to the end of the queue after it completes its turn on the port. The relative weighting of the scheduling of the high-priority queue to the low priority queue is programmable from 1:1 to 1:256 through the DMA global channel register using the DMA4\_GCR[23:16] ARBITRATION\_RATE bit field.

---

**NOTE:** The DMA4\_GCR[23:16] ARBITRATION\_RATE field does not depend on the DMA4\_GCR[13:12] HI\_THREAD\_RESERVED field. The ARBITRATION\_RATE field depends on the DMA4\_CCRi[26] WRITE\_PRIORITY bit and the DMA4\_CCRi[6] READ\_PRIORITY bit.

---

- Read/write port access scheduling policy

When either the read or write port becomes available, the port access scheduler selects the next logical channel for which to perform a DMA transaction from either the high- or low-priority queue.

When the current DMA transaction (single or burst access) is complete and the full DMA transfer is not finished, the logical channel returns to the tail of the queue. Because the port access scheduling is on a per-transaction basis, a logical channel can be queued repeatedly this way several times during its block transfer.

The sDMA module can have up to four outstanding read transactions and two outstanding write transactions in the system interconnect; four read and two write thread IDs exist. For an arbitration cycle to occur, these two conditions must be met:

- At least one channel is requesting.
- At least one free thread ID is available.

On an arbitration cycle, the scheduler grants the highest priority channel that has an active request, allocates the thread ID, and tags this thread as busy. At a given time, a channel cannot be allocated for more than one thread ID.

---

**NOTE:** If more than one channel is active, each channel is given a thread ID for the current service only, not for the whole channel transfer.

---

When only one channel is enabled, only one thread is allocated for the channel. In such a situation the channel can have maximum of four outstanding commands (without getting the responses) without rescheduling the channel at the end of each transaction. Each command can be either single access (8-bit, 16-bit or 32-bit) or burst access (2 x M, 4 x M, 8 x M or 16 x M, where M can be 8-bit, 16-bit or 32-bit).

When nonburst alignment is at the beginning of the transfer, the channel is rescheduled for each smaller access until burst-aligned. When the end of the transfer is not burst-aligned, the channel is rescheduled for each of the remaining smaller accesses.

For a logical channel transfer completion, when the last access is written to the destination, the logical channel becomes inactive. If enabled, an interrupt request is generated (see [Section 16.4.2.1, Interrupt Generation](#)).

#### 16.4.4 FIFO Queue Memory Pool

A FIFO queue memory pool provides buffering between the read and write ports. The hardware allocates the space dynamically to a number of FIFO queues, and each queue is associated with an active logical channel.

To avoid a memory pool overflow, if there are fewer entries in the FIFO queue memory pool than are required for the maximum configured source burst size of the next logical channel to be scheduled, the logical channel is returned to the tail of the queue, and the port access scheduler continues to search the queue until it finds a logical channel that can be scheduled.

The maximum FIFO depth that can be allocated to each individual logical channel can be limited globally through the `DMA4_GCR[7:0] MAX_CHANNEL_FIFO_DEPTH` bit field. This value should be configured to allow a fair allocation of the memory pool between the active channels.

A logical channel is scheduled if it has not yet reached its allocation limit, even if the access to be performed will exceed this limit. This means that the effective number of entries used by a particular logical channel is limited to the configured maximum entries per channel + channel maximum configured burst size (in words) 1.

### 16.4.5 Addressing Modes

A DMA transfer block consists of a number of frames (FN). Each frame consists of a number of elements (EN), and each element can have a size of 8, 16, or 32 bits (ES), as follows:

$$\text{transfer block size} = \text{FN} \times \text{EN} \times \text{ES}$$

The FN, EN, and ES are common for both the source and destination. However, the way in which the data is represented (addressing profile/mode) is independently programmable for the source and destination devices, using one of these four addressing modes:

- Constant: The address remains the same for consecutive element accesses.
- Post-increment: The address increases by the ES, even across consecutive frames.
- Single-index: The address increases by the ES plus the element index (EI) value minus 1 (even across consecutive frames).
- Double-index: The address increases by the ES plus the EI value minus 1 within a frame. When a full frame is transferred, the address increases by the ES plus the frame index (FI) value minus 1.

The ES, EI, and FI values are expressed in bytes. The EI and FI values can be positive or negative.

When calculating the EI and FI values, it is critical to note that, after an element is accessed, the logical channel address pointer equals the address of the last byte (highest address) of the accessed element. The correct value for the EI or FI should be such that, when added to the logical channel address pointer, results in the address of the first byte (lowest address) of the next element to be accessed.

The EI and FI values must be configured so that the address of each element in the transfer is aligned on an ES boundary.

Consequently, the single-index addressing mode with EI = 1 or double-index addressing mode with EI = 1 and FI = 1 is equivalent to post-increment addressing.

---

**NOTE:** The source and destination start addresses must also be aligned on an ES boundary.

---

When the address of an element to be accessed is not aligned on an ES boundary, the transfer is stopped and a misaligned address error interrupt occurs, if enabled (see [Section 16.4.2.1, Interrupt Generation](#)).

The `DMA4_CFNi` register configures the FN in a block.

The `DMA4_CENi` register configures the EN.

The `DMA4_CSDPi` register configures the ES.

The `DMA4_CSSAi` and `DMA4_CDSAi` registers configure the source and destination start addresses.

The `DMA4_CCRi` register configures the source and destination addressing modes.

The `DMA4_CSEIi`, `DMA4_CSFli`, `DMA4_CDEIi`, and `DMA4_CDFli` registers configure the source EI, source FI, destination EI, and destination FI, respectively.

The addressing profiles are expressed as equations as follows:

Equation 1. Constant addressing:

$$A(n + 1) = A(n)$$

Equation 2. Post-increment addressing:

$$A(n + 1) = A(n) + ES$$

Equation 3. Single-indexed addressing:

$$A(n + 1) = A(n) + ES + (EI - 1)$$

Equation 4. Double-indexed addressing:

When not at the end of a frame or transfer (that is, when the element counter  $\neq 0$ ):

$$A(n + 1) = A(n) + ES + (EI - 1)$$

When at the end of a frame but not at the end of the transfer (that is, when the element counter = 0 and the frame counter  $\neq 0$ ):

$$A(n + 1) = A(n) + ES + (FI - 1)$$

Calculate the element and frame index as follows:

Equation 5. Element index

$$EI = [(Stride EI - 1) * ES] + 1$$

Equation 6. Frame index

$$FI = [(Stride FI - 1) * ES] + 1$$

where:

A(n): Byte address of the element  $n$  within the transfer.

ES is in bytes, ES{1, 2, 4}.

EI is in bytes, specified in a configuration register, 32768 EI 32767.

Stride EI: The difference in the number of elements between the start of the current element  $n$  to the start of next element,  $n+1$ .

Element counter: A counter that is (re)initiated with the number of elements per frame or per transfer. Decreased by 1 for each element transferred. The initial value is configured in the register DMA channel element number, DMA4\_CENi.

FI is in bytes, specified in a configuration register, 2147483648 FI 2147483647.

Stride FI: The difference in the number of elements between the start of the last element of the current frame and the beginning of the first element of the next frame.

Frame counter: A counter that is (re)initiated with the FN per transfer. Decreased by 1 for each frame transferred. The initial value is configured in the register DMA channel frame number, DMA4\_CFNi.

Figure 16-7 shows how a stride EI and FI are defined. When handling complex configurations, using strides can make it easier to calculate EI and FI because you can calculate in elements instead of bytes. (This approach is used in the 90-degree clockwise image rotation example shown in Figure 16-11.) The double-index addressing example shown in Figure 16-7 uses ES = 4, EN = 2, EI = 5, FI = 5, and FN = 2.

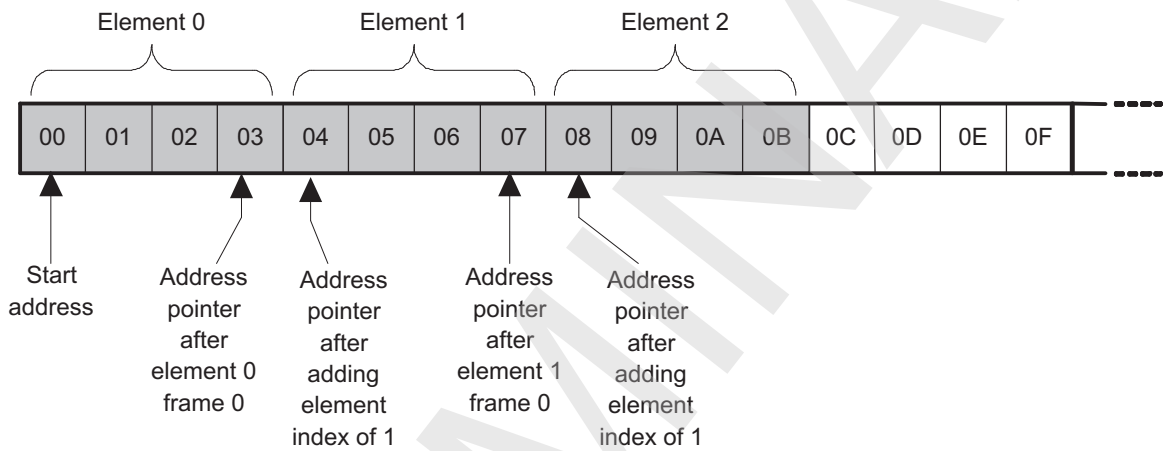

Figure 16-7 through Figure 16-10 show examples of addressing mode configurations. Table 16-9 lists parameter values for the examples.

**Figure 16-7. Example Showing Double-Index Addressing, Elements, Frames, and Strides**

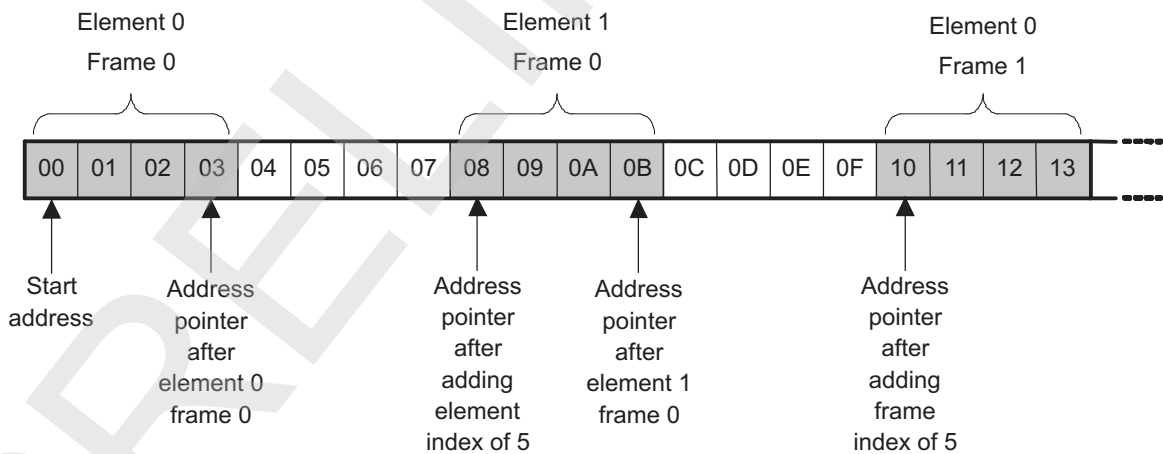

dma-011

**Figure 16-8. Addressing Mode Example (a)**

dma-010

**Figure 16-9. Addressing Mode Example (b)**

dma-009

**Figure 16-10. Addressing Mode Example (c)**

dma-008

**Table 16-9. Parameter Values for Addressing Mode Examples (a), (b), and (c)**

Parameter	Example (a)	Example (b)	Example (c)
Addressing mode	Single index (or post-increment)	Double index	Double index
Start address	0	0	8
ES	4 (32-bit)	4 (32-bit)	2 (16-bit)
EN	3	2	2
EI	1	5	1
FN	1	2	2
Frame index	N/A	5	-9

Double indexing can occur either on source (read) or destination (write). Equations for rotation of  $xx$  degrees on destination are obtained by taking equations for rotation of  $(360 - xx)$  degrees on source, and swapping the width ( $x$ ) and height ( $y$ ) of the image in them. The opposite is also true. Table 16-10 lists the equations for 90-, 180-, and 270-degree rotations.

**Table 16-10. Equations for Rotation**

		90 Rotation	180 Rotation	270 Rotation
Double indexing on destination (write)	Base address	$ES*(y-1)$	$ES*(x*y-1)$	$ES*y*(x-1)$
	EI	$ES*(y-1) + 1$	$1-2*ES$	$1-ES*(y + 1)$
	FI	$1 ES*[(x-1)*y + 2]$	$1-2*ES$	$1+ES*(x-1)*y$
Double indexing on source (read)	Base address	$ES*x*(y-1)$	$ES*(x*y-1)$	$ES*(x-1)$
	EI	$1-ES*(x + 1)$	$1-2*ES$	$ES*(x-1) + 1$
	FI	$1+ES*(y-1)*x$	$1-2*ES$	$1 ES*[(y-1)*x + 2]$

Table 16-11 and Figure 16-11 show the configuration required to perform a 90-degree clockwise rotation of a 240 x 160 pixel, 32-bit image. The EI, frame size, and FI values are configured so that the image is rotated line by line starting at the left end of the top line.

**NOTE:** The FI value for the destination is negative so that the first pixel of each subsequent line of the source image is written to the correct location at the destination.

Equation 5 and Equation 6 calculate the destination, FI and EI. The example assumes that the image lines are stored at consecutive addresses in memory, meaning that both EI and FI on the source side are 1.

**Rotations:**

Section 16.5.7, 90-Degree Clockwise Image Rotation, describes how to program an example of a 90-degree clockwise image rotation.

Observe that:

- One pixel = one element
- One line = one DMA frame
- Pixel size = element size = ES

**Table 16-11. Example Parameter Values for a 90-Degree Clockwise Image Rotation**

Parameter	Source Value	Destination Value
Bits per pixel	32	32
ES	4	4
Image width	SW	SH
Image height	SH	SW
Stride elements (stride EI)	1 element	SH
Stride frames (stride FI)	1 element	$-[(SW-1)*SH + 1] = 38,241$ elements
Start address	0x100000	$0x200000 + (SH - 1) \times ES = 0x20027C$
EN	SW	SW
EI	$[(Stride EI - 1) * ES] + 1 = 1$	$[(Stride EI - 1) * ES] + 1 = 637$
FN	SH	SH
FI	$[(Stride FI - 1) * ES] + 1 = 1$	$[(Stride FI - 1) * ES] + 1 = 152,967$

**Figure 16-11. Example of a 90-Degree Clockwise Image Rotation**

**16.4.6 Packed Accesses**

To pack data means to group data to match the bus size, thus optimizing a transfer. When the logical channel ES is less than the DMA module read/write port size, and the addressing profile supports it (post-increment mode or single- or double-index mode with EI = 1), the number of elements to transfer in each read/write port access can be maximized by specifying that the source or destination is packed through the channel DMA4\_CSDPi register. Thus:

- For a read/write port size of 32 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (four elements per access) and 16 bits (two elements per access).

- For a read/write port size of 64 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (eight elements per access), 16 bits (four elements per access), and 32 bits (two elements per access).

Depending on the start address and transfer length, the first or last packed access can be only partially filled. This is indicated to the source or destination using the byte-enable signals.

### 16.4.7 Burst Transactions

Transfer performance can be improved so that the source or destination and addressing profile supports it. This can be achieved by configuring the logical channel to perform burst transactions consisting of multiple instead of single accesses. The channel can be programmed to use burst sizes equal to 16, 32, or 64 bytes through the `DMA4_CSDPi` register, with the read burst size programmable independently of the write burst size. Typically, the optimal burst size is 64 bytes (16 accesses for a 32-bit read/write port size or 8 accesses for a 64-bit read/write port size).

To obtain the maximum benefit from burst transactions, the source and destination start addresses must be aligned with the burst size. If this is not the case, the start of the transfer can consist of a number of smaller (single or burst) transactions until the first burst size boundary is reached.

Similarly, if the end of the transfer is not aligned on a burst size boundary, the final part of the transfer can consist of a number of smaller transactions.

---

**NOTE:** If post-incrementing is used, data must be packed to DMA data-port width, to use burst.

---

### 16.4.8 Endianism Conversion

The source and destination are each specified as little-endian or big-endian through the `DMA4_CSDPi` register for the particular logical channel. If the endianism of the source and destination differ, and if the logical channel ES is less than the sDMA module read/write port size, an endianism conversion is applied to the data before it is written to the destination.

When transferring data between a source and a destination with different endianism, it is important to specify an ES that equals the type of data being transferred to preserve the correct data image at the destination.

In the system, endianism conversion can be performed in more than one place. It is possible to instruct the source and/or destination to lock the endianism (that is, to not perform a conversion) through the logical DMA channel `DMA4_CSDPi` register.

### 16.4.9 Transfer Synchronization

A logical channel can be programmed for either software-triggered or hardware synchronized transfers.

#### 16.4.9.1 Software Synchronization

A transfer is software-triggered when the logical channel is set up and started by software. To specify a software-triggered transfer, set the channel DMA `DMA4_CCRi[4:0]` and `DMA4_CCRi[20:19]` bit fields to 0. The transfer starts as soon as the DMA `DMA4_CCRi[7]` bit is set (when it enters the scheduling process).

#### 16.4.9.2 Hardware Synchronization

A transfer is hardware-synchronized if the logical channel activation is driven by hardware requests from the source or destination target. A hardware-synchronized transfer is specified by configuring the DMA request line number in the channel `DMA4_CCRi` register to a value that corresponds to the DMA request line from the source or destination that generates the DMA requests. The DMA request numbers to be configured are specified in the DMA request mapping (see [Table 16-8](#)).

Specify the DMA request number in the `DMA4_CCRi[4:0]` SYNCHRO\_CONTROL and `DMA4_CCRi[20:19]` SYNCHRO\_CONTROL\_UPPER bit fields. After the `DMA4_CCRi[7]` ENABLE bit is set, the logical channel becomes enabled but not activated (it does not enter the scheduling process), which means that channel registers are not updated until the first DMA request is received.

**NOTE:** The channel synchronization control registers are 1-based. For example, to enable the S\_DMA\_1 request, the DMA4\_CCRi[4:0] SYNCHRO\_CONTROL bit field must be set to 0x2 (DMA request number + 1).

**NOTE: DMA Request Line**

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared among several chained logical channels.

For hardware synchronization, the amount of data to be transferred for each assertion of the DMA request line is configured through the frame synchronization (FS) and block synchronization (BS) bits in the logical channel DMA4\_CCRi register and the DMA4\_CCRi[5] FS and DMA4\_CCRi[18] BS bits, respectively.

The amount of data can be any of the following:

- A single element transfer: A complete element defined by data type. For example, 8/16/32 bits are transferred in response to a DMA request.
- A full frame: A complete frame of several elements is transferred in response to a DMA request.
- A full block (a full channel transfer): A complete block of several frames is transferred in response to a DMA request.
- A full packet (a full channel transfer): A complete packet of several elements is transferred in response to a DMA request.

Packets allow the size of each part of the full DMA transfer to be configured independently of the organization of the data to be transferred (typically a number of elements). This can be useful when the source or destination has a buffer (such as a FIFO queue) with a size unrelated to the frame size of the transfer. The packet size then can be set to the size of the buffer.

Packet transfer must be used only where the source or destination is addressed in constant addressing mode, because FI registers are reused to specify the packet size.

To support the burst mode, the logical channel must also be configured in target-port packed access mode.

The packet size is configured based on the DMA4\_CCRi[24] SEL\_SRC\_DST\_SYNC bit through either the channel DMA4\_CDFIi register (source synchronized) or the DMA4\_CSFIi register (destination synchronized).

When the logical channel transfer block is not an exact multiple of the packet size, the final packet consists of the remaining elements in the transfer, using burst or single accesses to complete the block transfer.

The maximum transfer size, regardless of the packet size, is always as follows:

$$\text{Block\_size} = \text{Number\_of\_Frame\_in\_Block} * \text{Number\_of\_Element\_in\_Frame} * \text{Element\_Size}$$

- Synchronized at the source

The DMA module optimizes the transfer with respect to the number and size of burst transactions for the given source and destination addressing profiles and configured maximum burst sizes. When writing to the destination is slower than reading from the source, data is buffered in the channel FIFO queue. If the transfer is packet-synchronized at the source, the end-of-packet interrupt is disabled (see [Section 16.4.13, Reprogramming an Active Channel](#)).

For a source synchronized transfer, buffering can be enabled or disabled by setting the DMA4\_CCRi[25] BUFFERING\_DISABLE bit. For a packet source synchronization with buffering disabled and the packed/burst across the packet boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the packet transfer size. However, for a packet source synchronized transfer with buffering enabled and with the packed/burst across the packet boundary, the DMA module waits for the next DMA request(s) to read enough data to issue an atomic packed/burst write transaction (assuming that the address is packed/burst aligned).

**NOTE:** Buffering is not performed between frames, even if it is enabled. If the packed/burst is across the frame boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the frame transfer size.

- Synchronized at the destination

The performance of a hardware-synchronized transfer can be improved by using the prefetch mode, enabled through the channel [DMA4\\_CCRi\[23\]](#) PREFETCH bit. Data is prefetched on the read port side before the DMA request received and buffered in the FIFO queue. Up to a full transfer block can be prefetched, although this can be limited by the specified maximum channel FIFO queue depth (see [Section 16.4.4, FIFO Queue Memory Pool](#)).

Buffering disable is not allowed for a destination-synchronized transfer.

**NOTE:** Behavior is undefined when prefetch is enabled and a transfer is synchronized to the source.

Regardless of whether buffering is enabled, the last transaction in the frame or in the block is write nonposted (WNP) even if the write mode is specified as write last nonposted (WLNP; the [DMA4\\_CSDPi\[17:16\]](#) WRITE\_MODE bit field = 0x2). However, in a packet synchronization mode, the last transaction of each packet in the transfer is WNP only if the buffering disable is on (even if the write mode is specified as WLNP).

Regardless of whether buffering is enabled, the packet interrupt is not generated in the packet source synchronized mode.

#### CAUTION

The [DMA4\\_CCRi\[25\]](#) BUFFERING\_DISABLE bit must be filled with an allowed value, as specified in [Table 16-12](#).

**Table 16-12. Buffering Disable**

	<b>BUFFERING_DISABLE</b> (0: Buffering enable, 1: Buffering disable)	
Destination synchronized	0	Allowed
	1	Not allowed
Source synchronized	0	Allowed
	1	Allowed

- Synchronized transfer monitoring using CDAC ([DMA4\\_CDACi](#)):

Context is restored only when the channel becomes active on a DMA request (not at software enable). The channel is software-enabled first, and then a DMA request is asserted followed by the first context restore.

The CDAC register is writable; thus, the CDAC can be initialized to monitor the transfer and determine whether the transfer is started (for more information, see [Section 16.5.4, Synchronized Transfer Monitoring Using CDAC](#)).

**NOTE:** For 16-bit transactions, start reading from or writing to the LSByte first to enable the register update. This is not an issue for 32-bit read-write transactions.

### 16.4.10 Thread Budget Allocation

When several concurrent channels are latency critical and hardware synchronized, a specific latency cannot be ensured until the target is served. This situation occurs when the number of concurrent channels is greater than the number of available threads.

---

**NOTE:** Four threads are available on the read port, and two threads are available on the write port.

---

For a hardware-synchronized transfer (memory to peripheral), a minimum bandwidth for a latency-critical transfer must be ensured to avoid collisions between two hardware requests.

Because it is latency critical, the software user is responsible for the following:

- Programming the synchronized channel as a high-priority channel
- Reserving one or several threads for high-priority channels

The proposed implementation is as follows (see [Section 16.5.5, Concurrent Software and Hardware Synchronization](#)):

Prevent the regular channel queue from exceeding more than a programmable (3, 2, or 1) number of threads on the read port and no more than one thread on the write port. This number can be set in the global register [DMA4\\_GCR\[13:12\]](#).

The thread reservation is programmable for maximum use of thread resources for concurrent, low-priority channel transfer. Programmability can also allow a partial throughput control by limiting in software the number of concurrent outstanding requests that break the pipelining.

Depending on the [DMA4\\_GCR \[13:12\]](#) value, the following threadID on the read/write ports are allocated for a high-priority channel:

Read port priority thread reservation:

- [DMA4\\_GCR\[13:12\] = 0x0](#) => No ThreadID is reserved for high-priority channels.
- [DMA4\\_GCR\[13:12\] = 0x1](#) => Read ThreadID 0 is reserved for high-priority channels.
- [DMA4\\_GCR\[13:12\] = 0x2](#) => Read ThreadID 0 and Read ThreadID 1 are reserved for high-priority channels.
- [DMA4\\_GCR\[13:12\] = 0x3](#) => Read ThreadID 0, Read ThreadID 1, and Read ThreadID 2 are reserved for high-priority channels.

Write port priority thread reservation:

- [DMA4\\_GCR\[13:12\] = 0x0](#) => No ThreadID is reserved for high-priority channels
- [DMA4\\_GCR\[13:12\] = 0x1](#) => Write ThreadID 0 is reserved for high-priority channels.
- [DMA4\\_GCR\[13:12\] = 0x2](#) => Write ThreadID 0 is reserved for high-priority channels.
- [DMA4\\_GCR\[13:12\] = 0x3](#) => Write ThreadID 0 is reserved for high-priority channels.

Regardless of whether the enabled channels are high priority, only the setting of the [DMA4\\_GCR\[13:12\]](#) value forces the thread reservation to these values. Set the appropriate value to avoid losing threads using only regular channels.

To have an independent read and write priority context, a per-channel bit ([DMA4\\_CCRI\[26\]](#)) is added for write priority, and the previous priority bit becomes read priority bit ([DMA4\\_CCRI\[6\]](#)).

---

**NOTE:** The device has one priority bit per logical channel, not one priority bit per port.

---

### 16.4.11 FIFO Budget Allocation

To avoid fully occupying the FIFO with a high-priority transfer while low-priority channels wait in the arbitration queue, two separate FIFO budgets are specified: one for high-priority channels and one for low-priority channels. This is defined in the [DMA4\\_GCR](#) register, allowing the user to share the FIFO budget between the low- and high-priority channels. The amount of the FIFO allocated by the low- and high-priority channels is fixed by the value set in the [DMA4\\_GCR\[15:14\]](#) HI\_LO\_FIFO\_BUDGET field. The maximum channel FIFO depth is limited by the HI\_LO\_FIFO\_BUDGET field as follows:

If the channel is low priority:

- When HI\_LO\_FIFO\_BUDGET = 0x1, then low priority cannot exceed 75 percent of the total FIFO.
- When HI\_LO\_FIFO\_BUDGET = 0x2, then low priority cannot exceed 25 percent of the total FIFO.
- When HI\_LO\_FIFO\_BUDGET = 0x3, then low priority cannot exceed 50 percent of the total FIFO.

If channel is high priority

- When HI\_LO\_FIFO\_BUDGET = 0x1, then high priority cannot exceed 25 percent of the total FIFO.
- When HI\_LO\_FIFO\_BUDGET = 0x2, then high priority cannot exceed 75 percent of the total FIFO.
- When HI\_LO\_FIFO\_BUDGET = 0x3, then high priority cannot exceed 50 percent of the total FIFO.

The user is responsible for performing the following equation:

- For a high-priority channel: (Per\_Channel\_Maximum FIFO Depth + 1) x Number of High Channel =< High Budget FIFO
- For a low-priority channel: (Per\_Channel\_Maximum FIFO Depth + 1) x Number of Low Channel =< Low Budget FIFO

---

**NOTE:** Ensure that *Number of High Channel* means *Number of Active High-Priority Channel* and that *Number of Low Channel* means *Number of Active Low-Priority Channel*.

---

#### 16.4.12 Chained Logical Channel Transfers

Chaining multiple logical channels permits transfers consisting of multiple parts to be executed without repeated software intervention. This results in better performance than the alternative of software setting up and starting each transfer separately. Each part of a chained transfer can have the data addressed in a different manner that permits the programming of a variety of complex transfers. For example:

- Interlaced video data with one logical channel configured to transfer the even lines and another logical channel configured to transfer the odd lines
- Protocol headers with a separate DMA4 channel configured to transfer each field in the header

Channels can be chained through each channel [DMA4\\_CLNK\\_CTRLi](#) register. When the transfer for the first channel completes, the next channel in the chain is enabled. The number of channels in the chain that are configured for hardware-synchronized transfers is flexible (although typically it might be all, none, or just the first one). The DMA request line number should be set to 0 to specify that any or all of the channels in a chain are software-triggered or nonsynchronized.

The last channel in a chain can be chained to the first channel to create a continuously looping chain. The continuously looping transfer can be stopped on the fly at a specific channel by disabling the [DMA4\\_CLNK\\_CTRLi\[15\]](#) ENABLE\_LNK bit. The looping transfer stops after the specified channel transfer is complete.

---

**NOTE: DMA Request Line**

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

---

For more information on the programming model, see [Section 16.5, sDMA Basic Programming Model](#).

#### 16.4.13 Reprogramming an Active Channel

A currently active logical DMA channel can be disabled through the [DMA4\\_CCRi\[7\]](#) ENABLE bit. When an ongoing transaction is complete and the read-active and write-active bits in the [DMA4\\_CCRi](#) register ([DMA4\\_CCRi\[9\]](#) RD\_ACTIVE and [DMA4\\_CCRi\[10\]](#) WR\_ACTIVE) are reset, the channel can be reprogrammed for a new transfer.

#### 16.4.14 Packet Synchronization

A packet transfer notion is related to the behavior of some peripherals, which have certain buffering capability and requires to transfer the buffer content once an element number threshold is reached (a hardware DMA request is generated). To associate a frame synchronization to each DMA request is possible, but this limits the maximum transfer size. Indeed the maximum transfer size is proportional to the FIFO depth of the peripheral:

maximum\_transfer\_size = peripheral\_FIFO\_depth x number\_of\_frame\_in\_block

The packet synchronization allows to dissociate the transfer size from the FIFO depth of the peripheral. Only Constant addressing mode is allowed on a read port or a write port if source target or destination target is packet synchronized respectively.

*Example:*

Consider a camera interface with a FIFO\_depth of 128 words and a FIFO\_element\_number\_threshold of 128, and a picture to transfer with a size 320 lines by 240 columns. If frame synchronization is associated with each DMA request then the maximum transfer size that can be performed is  $128 \times 2^{16}$  words. In this case, a frame is 128-word long, which does not fit the size of a line, and it is not possible to generate an interrupt at the end of line. However, by introducing the packet transfer notion, which is related to the peripheral FIFO behavior/structure, the maximum transfer size (maximum\_transfer\_size =  $2^{24} \times 2^{16}$  words) is independent of both peripheral\_FIFO\_depth and FIFO\_element\_number\_threshold. This allows a long-enough transfer within one channel context and rotation operation on a large image format.

The main features of DMA Packet transfer are as follows:

- DMA Packet\_Data\_Size for each DMA Request: the Peripheral\_element\_number\_threshold (the number of elements in a packet) shares the DMA4\_CSFl<sub>i</sub> and DMA4\_CDFl<sub>i</sub> configuration registers. If the peripheral is the source target, the addressing mode is constant, and the DMA4\_CSFll[15:0] bit field is used to specify the packet data size in the DMA4\_CSFll register. The user must set the DMA4\_CCRi[24] SEL\_SRC\_DST\_SYNC bit to 1. If the peripheral is the destination target, the addressing mode is constant, the DMA4\_CDFll[15:0], is used to specify the packet data size (PKT\_ELNT\_NBR), and the bit field [31:16] is unused. To specify the packet data size in the DMA4\_CDFll register, the user must set the DMA4\_CCRi[24] SEL\_SRC\_DST\_SYNC bit to 0.

---

**NOTE:** The packet size can be a submultiple or non-submultiple of a frame size. If DMA Packet\_Data\_Size is aligned on the DMA channel block data size boundary, then DMA transfers the last data in the channel block boundary, and stops at the block boundary for the last packet DMA Request. If the Packet\_Data\_size is not aligned on the block boundary, the remaining data smaller than a packet size are transferred using burst or single accesses to complete the block.

---

- DMA Packet\_Data\_Transfer does not affect DMA channel capabilities in term of packing and bursting. The Packet synchronization mode is active when DMA4\_CCRi[5] FS = DMA4\_CCRi[18] BS = 1. Then
  - if DMA4\_CCRi[24] SEL\_SRC\_DST\_SYNC=0, the DMA4\_CDFll[15:0] bit field gives the number of elements in the packet and the DMA4\_CDFll[31:16] bit field is unused for the packet size.
  - if DMA4\_CCRi[24] SEL\_SRC\_DST\_SYNC=1, the DMA4\_CSFll[15:0] bit field gives the number of element in the packet and the DMA4\_CSFll[31:16] bit field is unused for the packet size.

---

**NOTE:** The maximum transfer size, regardless of the packet size, is always:  
 Block\_size = Number\_of\_Frame\_in\_Block x Number\_of\_Element\_in\_Frame x Element\_Size.

If DMA channel packet/burst access is across the packet boundary, the DMA hardware automatically splits this packing/burst access into multiple smaller accesses that are aligned on the packet boundary. Otherwise, the DMA transfers data as a usual packing/burst access.

---

### 16.4.15 Graphics Acceleration Support

The sDMA supports two graphic acceleration features:

- Transparent copy
- Constant fill

Only one of these features can be enabled at a time through the DMA4\_CCRi register for the particular logical DMA channel.

The transparent copy feature enables specification of a particular color through the DMA4\_COLORi register, so that when it is recognized in the data from the source, it is not copied to the corresponding location in the destination, but instead leaves the data in the corresponding location in the destination as it is.

Figure 16-12 shows the 2-D graphic transparent color block diagram.

**Figure 16-12. 2-D Graphic Transparent Color Block Diagram**

The constant fill feature provides the ability to specify a particular color through the [DMA4\\_COLORi](#) register for every specified location in the destination. In this case, the transfer consists only of writing to the destination without reading from a source.

Both features support 8 bpp (bits per pixel), 16 bpp, and 24 bpp, depending on what is specified as the DMA transfer ES via the [DMA4\\_CSDPi](#) register. An ES of 32 bits corresponds to 24 bpp. During a 32-bit (24 bpp) transfer, the 8 most-significant bits (MSB) ([31:24]) are 0. Both features are compatible with packed and burst transactions.

#### 16.4.16 Supervisor Modes

A logical DMA channel can be configured to operate in supervisor mode through the [DMA4\\_CCRi\[22\]](#) SUPERVISOR bit. This must be done using supervisor access. Once a channel is configured in supervisor mode, the channel configuration is protected from nonsupervisor accesses. All DMA transactions on a supervisor channel are supervisor transactions.

#### 16.4.17 Posted and Nonposted Writes

A logical channel can be configured in its [DMA4\\_CSDPi\[17:16\]](#) bits to use one of three write access handshake modes for the destination:

- Nonposted write: Each write must complete before transfer can continue or complete.
- Posted write: Transfer continues without waiting for each write to complete (might improve performance with slow devices).
- Posted with final write nonposted: Transfer continues without waiting for each write to complete, but final write is completed before transfer can complete.

#### 16.4.18 Disabling a Channel During Transfer

When a channel is disabled during a transfer, the channel undergoes an abort, unless it is hardware source synchronized with buffering enabled ([DMA4\\_CCRi\[25\]](#) BUFFERING\_DISABLE = 0). If this is the case, the FIFO is drained to prevent the loss of data. See [Section 16.4.19, FIFO Draining Mechanism](#), for details about this feature.

#### 16.4.19 FIFO Draining Mechanism

When a source synchronized channel is disabled during a transfer, then the current hardware request (element/packet/frame/block) service is completed and the channel [DMA4\\_CCRi\[9\]](#) RD\_ACTIVE bit is set to 0, which means the channel is not active on the read port. The remaining data in the corresponding disabled channel FIFO is drained onto the write port and transferred to the programmed destination as in normal transfer.

At the end of the draining the `DMA4_CCRi[10] WR_ACTIVE` bit is set to 0 (channel is no longer active on the write port) and if the `DMA4_CICRI[12] DRAIN_END_IE` is set to 1, the `DMA4_CSRI[12] DRAIN_END` status bit is updated and an interrupt is generated.

Once a channel is disabled during a transfer, it must wait for `DMA4_CCRi[9] RD_ACTIVE` and `DMA4_CCRi[10] WR_ACTIVE` to become 0 before being reenabled for a new transfer. The FIFO drain for a channel occurs only in the following cases:

- If the channel is a source synchronized channel and `DMA4_CCRi[25] BUFFERING_DISABLE = 0` and
- If the channel is not a solid fill channel and
- If the channel is not a transparent and copy channel and
- If the channel is a hardware, synchronized channel

---

**NOTE:** For a self-linked or chain-linked channel, the user must disable the `DMA4_CLNK_CTRLi[15] ENABLE_LINK` bit before disabling the channel.

---

In all other cases, the channel undergoes an abort.

## 16.4.20 *Linked List*

### 16.4.20.1 Overview

The sDMA supports the logical transfer descriptor loader feature. A transfer descriptor represents a set of values that maps to a set of logical channel configuration registers.

A logical channel transfer descriptor can be loaded by DMA from memories, and then successive transfer descriptors can be autonomously loaded based on a linked-list scheme. This enables DMA4 scatter gather transfers with minimum MPU support by removing successive channel configuration processing and associated interrupt handling overheads. It also optimizes DMA4 channel resources by enabling efficient transfer serialization on a single logical channel versus concurrent (multiple) logical channel use.

Different types of transfer descriptors are supported (full or partial logical channel configuration registers are set). This optimizes the memory size required for storing a long linked list, because parameter changes are limited to only a few logical channel configuration registers.

### 16.4.20.2 Link-List Transfer Profile

A linked-list transfer can be seen as a super-block transfer (where the block is composed of FN frames and each frame includes EN elements). The block size (FN x EN x ES) can be changed in the linked list by loading an updated transfer descriptor.

The end of the super block is signaled in the last descriptor associated with the last block. Generally, for a given link-list transfer, the logical channel is set at the beginning of the transfer and the logical channel configurations for the subsequent blocks are slightly changed. Thus, the descriptor can be limited to an update of only few parameters, such as FN or EN. This assumes that the content of unmodified registers is preserved when a new descriptor is loaded.

A transfer descriptor is composed of a set of channel configuration register values with the addition of the next-descriptor pointer register (`DMA4_CNDPi`) and a channel-descriptor parameter register (`DMA4_CDPi`). The next-descriptor pointer is the 32-bit address pointer from where the next transfer descriptor is to be loaded. The next-descriptor pointer is mapped depending on the descriptor type (1, 2, or 3).

### 16.4.20.3 Descriptors

A transfer descriptor is a set of values that maps to a set of logical channel configuration registers. The descriptor contains the parameters associated with a transfer profile (transfer size, source or destination addresses, etc). Four different types of transfer descriptors are supported to optimize the memory size required to store a long linked list and to minimize MPU use to create and maintain the descriptor list.

A transfer descriptor is a list of 32-bit values. A descriptor must be 32-bit aligned in memory. Only the 30 least-significant bits (LSBs) of the next-descriptor address pointer are updated from the descriptor, and the DMA4 forces the 2 LSBs to 0 on generation of the pointer address. The descriptor size is variable depends on the descriptor type and the `Nxt_Dv` and `Nxt_Sv` bit fields.

Transfer descriptor bit mapping is the same as DMA4 logical-channel configuration register bit mapping, with the following exceptions:

- `Src_Element_index` and `Dst_Element_index` are concatenated in the same 32-bit location.
- `DMA4_CICRi` (interrupt event mask)
- CFN (frame number)
- Bit fields
  - P: Corresponds to the `PAUSE_LINK_LIST` bit:
    - When set to 1 in the descriptor, the channel is suspended when the descriptor load completes.
    - The user must not set the `PAUSE_LINK_LIST` bit through the configuration port. Otherwise, behavior is undefined.
    - When set to 0 (through the configuration port) after pause, the linked-list channel resumes its transfer (either descriptor load or data load).
  - B: Corresponds to the end-of-block enable bit (`BLOCK_IE`) of the `DMA4_CICRi` register; valid only for type 3. This value is don't care for descriptor types 1 and 2, where `DMA4_CICRi` is fully specified.
  - `Nxt_Dv`, `Nxt_Sv`: Mapped in the `DMA4_CDPi` register. They indicate one of the following possibilities:
    - Next descriptor contains an updated destination or source address.
    - Next descriptor does not update the source or destination address, but increments the last source or destination address (from the end of the last transfer).
    - The next source address and/or destination address are the last valid ones in the configuration memory. This means that the corresponding location in the configuration memory is not updated (assuming that they were initialized at least once in the past). This is also called wrapping addressing.
  - `Next_Descriptor_Type`: Specifies the next descriptor type that corresponds to the `NEXT_DESCRIPTOR_TYPE` bit field in the `DMA4_CDPi` register

#### 16.4.20.3.1 Type 1

A type 1 descriptor includes the overall channel configuration register value to be loaded (global registers are not part of the type 1 descriptor). This descriptor is used primarily when major changes are required:

- Channel read or write access profiles must be modified, for example, bursting and packing (included in the `DMA4_CSDPi` register)
- Attach a new DMA request to the same channel or change the priority or change the access privilege (included in the `DMA4_CCRi` register)
- Enable solid or transparent color fill (included in the `DMA4_CCRi` and `DMA4_COLORi` registers)
- Enable a channel link (included in the `DMA4_CLNK_CTRLi` register)

Table 16-13 shows a type 1 descriptor.

Table 16-13. Type 1

	3	3	2	2	2	2	2	2	2	2	2	2	2	2	2	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	9	8	7	6	5	4	3	2	1	0

16.4.20.3.2 Type 2

A type 2 descriptor includes the overall logical channel transfer address register and transfer format register to be loaded. This descriptor enables 2D addressing linked-list transfer (for example, a multimedia application where 2D objects are moved in a link). Table 16-14 shows a type 2 descriptor with source and destination address updates. Table 16-15 shows a type 2 descriptor with one source or destination address update.

Table 16-14. Type 2 With Source and Destination Address Updates

**16.4.20.3.3 Type 3**

A type 3 descriptor is limited to a few logical channel transfer address registers and transfer format registers to be loaded. This descriptor enables simple 1D addressing link transfer (for example, scatter-gather or ping-pong memory movement using a linked list). [Table 16-16](#) shows a type 3 descriptor with source and destination address updates. [Table 16-17](#) shows a type 3 descriptor with one source or address destination update.

**16.4.20.4 Linked-List Control and Monitoring****16.4.20.4.1 Transfer Mode Setting**

Four descriptor types are available in [DMA4\\_CDPi\[9:8\] TRANSFER\\_MODE](#) to distinguish the different transfer modes:

- [DMA4\\_CDPi\[9:8\] TRANSFER\\_MODE = 00](#): The current channel is using normal mode.
- [DMA4\\_CDPi\[9:8\] TRANSFER\\_MODE = 01](#): The current channel is using link-list channel mode for a type 1, 2, or 3 descriptor.

The reset value is normal mode ([DMA4\\_CDPi\[9:8\] TRANSFER\\_MODE = 0](#)).

#### 16.4.20.4.2 Starting a Linked List

Like a nonlinked-list transfer, a link transfer starts under host control by enabling the associated logical channel (set the `DMA4_CCRi[7]` ENABLE bit to 1). The `DMA4_CDPi[10]` FAST bit sets the start mode of the link-list transfer:

In nonfast-start mode, the logical channel configuration is fully initialized so that the transfer can start without descriptor loading.

In fast-start mode, the descriptor pointer and other inputs are given. The channel starts by loading the descriptor and then starts the data transfer phase.

#### 16.4.20.4.3 Monitoring a Linked-List Progression

In addition to the `DMA4_CCENi` (remaining elements) and `DMA4_CCFNi` (remaining frames) registers that are used to monitor the transfer progress, a per-channel register, `DMA4_CCDNi` (channel current active descriptor number), monitors which descriptor in the list is active. The user must initialize the `DMA4_CCDNi` register to 0 during the initial configuration. When the `DMA4_CCDNi` register is updated, the `DMA4_CCFNi` and the `DMA4_CCENi` registers are updated. The user must also initialize the `DMA4_CCFNi` and `DMA4_CCENi` registers to 0xFFFF and to 0xFFFFFFFF, respectively, to track the effective transfer start of synchronized transfer.

#### 16.4.20.4.4 Interrupt During Linked-List Execution

Any logical channel source of interrupt can be triggered during a linked-list execution, if the interrupt source is enabled during the initial configuration in `CICR`. The `DMA4_CICRi` register can also be updated during the linked-list execution if descriptor types 1 and 2 are used.

The use of an interrupt event in a link execution can be difficult, because the link can progress in parallel with interrupt service routine (ISR) execution. This makes it difficult to synchronize them unless system assumptions are used. The most appropriate synchronization model is to get an interrupt-only on linked-list completion, when the last transfer block is complete. This prevents the interrupt from occurring during the link execution. An end-of-super-block interrupt event available in the `DMA4_CICRi` and `DMA4_CSRi` registers can be enabled at initial configuration or when using descriptor types 1 and 2. To prevent the use of descriptor type 1 or 2 to update `BLOCK_IE` (full `DMA4_CICRi` update), a dedicated `BLOCK_IE` bit field is also available in a type 3 descriptor.

#### 16.4.20.4.5 Pause a Linked List

When the channel is suspended, it remains enabled.

The pause behaves differently, depending on the transfer mode:

- Normal transfer mode: If the user sets the `DMA4_CDPi[7]` PAUSE\_LINK\_LIST bit to 1, the channel completes the current read and write transactions and then suspends the channel. The channel can be resumed by setting the channel `DMA4_CDPi[7]` PAUSE\_LINK\_LIST bit to 0.
- Linked-list type 1, 2, or 3 mode: The user must not set the `DMA4_CDPi[7]` PAUSE\_LINK\_LIST bit through the configuration port; otherwise, transfer behavior is undefined.
  - A PAUSE\_LINK\_LIST bit (P) is set to 1 in the descriptor.
    - The channel is suspended after the descriptor load, translation, and configuration memory update are complete.
    - The linked list can be resumed by resetting the `DMA4_CDPi[7]` PAUSE\_LINK\_LIST bit (through the configuration port).

#### 16.4.20.4.6 Stop a Linked List (Abort or Drain)

The channel can be stopped for a drain or an abort. These cases are exclusive.

##### 16.4.20.4.6.1 Drain

- Drain conditions:

A channel is a drain candidate if it is a hardware-source-synchronized transfer with `DMA4_CCRi[25]` BUFFERING\_DISABLE = 0 and should not be doing any of the graphics operation (transparent copy

or solid-color fill).

- Drain trigger:  
A drain candidate channel is drained if it is disabled (`DMA4_CCRi[7] ENABLE = 0`) or if it receives a transaction error on the read port.
- Drain behavior with a type 1, 2, or 3 descriptor. Drain trigger can occur in two situations:
  - During descriptor loading: Any ongoing current transaction is complete and the channel is aborted.
  - During data loading: The read is completed at the boundary of the request (element/frame/packet/block boundary), the FIFO is drained to the destination, and then a `DRAIN_END` interrupt can be asserted.

#### 16.4.20.4.6.2 Abort

- Abort condition:  
A channel is an abort candidate if it is software-synchronized, hardware-destination-synchronized, solid color-fill, transparent-color fill, or hardware-source-synchronized with `DMA4_CCRi[25] BUFFERING_DISABLE = 1`.
- Abort trigger:  
A channel is an abort candidate if it is disabled (`DMA4_CCRi[7] ENABLE = 0`), if it receives a transaction error on the read or write port, or if there is a `MISALIGNMENT_ERROR`.
- Abort behavior with a type 1, 2, or 3 descriptor:  
If an abort trigger occurs, the channel aborts immediately after completion of current read/write transactions and then the FIFO is cleaned up.  
In type 1, 2, or 3, if an abort trigger or drain trigger occurs during the descriptor load phase, the channel aborts.

#### 16.4.20.4.7 Status Bit Behavior

This section describes the behavior of the `DMA4_CSRi[6] SYNC`, `DMA4_CCRi[9] RD_ACTIVE` and `DMA4_CCRi[10] WR_ACTIVE` status bits:

- For a hardware-synchronized channel in linked-list mode, the `DMA4_CSRi[6] SYNC` bit becomes active (`DMA4_CSRi[6] SYNC = 1`) when the first data load transaction is scheduled and remains active until the last data load transaction in the block (not super block) is descheduled (`DMA4_CSRi[6] SYNC = 0`). The `SYNC` bit is not active during the descriptor load phase.
- The `DMA4_CCRi[9] RD_ACTIVE` bit is active during the data load phase and the descriptor load phase. It becomes active when the first read transaction is scheduled. It becomes inactive:
  - When (during the descriptor load phase) the last descriptor write request is descheduled
  - When (during the data load phase) the last read transaction in the block (not super block) is descheduled for software-synchronized transfer or destination-synchronized transfer with prefetch enabled
  - When (during the data load phase) the last read transaction in the request (element/frame/packet/block sync) is descheduled for hardware-source-synchronized transfer or hardware-destination-synchronized transfer without prefetch
- The `DMA4_CCRi[10] WR_ACTIVE` bit is active only during the data load phase. It becomes active when the first write transaction is scheduled and becomes inactive:
  - Until the last write transaction in the block (not super block) is descheduled and the FIFO is cleaned up for software-synchronized transfer
  - Until the last write transaction in the request (element/frame/packet/block sync) is descheduled and the FIFO is cleaned up for hardware-source-synchronized transfer (with `DMA4_CCRi[25] BUFFERING_DISABLE = 0`) or hardware-destination-synchronized transfer.

#### 16.4.20.4.8 Linked-List Channel Linking

Channel linking for inter and intra super blocks is supported for type 1, 2, and 3 descriptors.

Assume that CHx and CHz are linked-list channels using generic descriptors. If CHx is composed of N descriptors and CHz is composed of M descriptors, then in nonfast mode,

CHx: CHx[Data1]-> CHx[DES1] -> . -> CHx[DESN]->CHx[DataN + 1]

CHz: CHz[Data1]-> CHz[DES1] -> . -> CHz[DESM]->CHz[DataM + 1]

It is possible to link CHx to CHz or CHx to itself after the completion of the CHx transfer (end of super block). To do this, the user must set the [DMA4\\_CLNK\\_CTRLi\[15\] ENABLE\\_LNK](#) bit to 1 and the [DMA4\\_CLNK\\_CTRLi\[4:0\] NEXTLCH\\_ID](#) bit to z (or to x for self linking) through the last descriptor using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]-> CHx[DES1] -> . -> CHx[DESN]->CHx[DataN+1] -> CHz: CHz[Data1]-> CHz[DES1] -> . -> CHz[DESM]->CHz[DataM+1]

It is also possible to link CHx to CHz during the CHx transfer and before the end of super block. The user must set the [DMA4\\_CLNK\\_CTRLi\[15\] ENABLE\\_LNK](#) bit to 1 and the [DMA4\\_CLNK\\_CTRLi\[4:0\] NEXTLCH\\_ID](#) bit to z through descriptor p (CHx[DESp]) using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]-> CHx[DES1] ->.-> CHx[DESp]->CHx[Data(p + 1)] -> CHz[Data1]-> CHz[DES1] -> .

The user must continue the linking until channels CHx and CHz complete their super-block transfers; otherwise, the channels remain enabled.

---

**NOTE:** In channel linking, the head of a chain can be in fast mode or nonfast mode. All channels that are not in the head of the chain can be in nonfast mode only. In self-linking, the channel cannot be in fast mode.

---

---

**NOTE:** If channel CHx links to CHz in the middle of the superblock transfer (remember link bit can be set through Type-1 descriptor load), CHx will get disabled after the corresponding data load and enables the channel CHz.

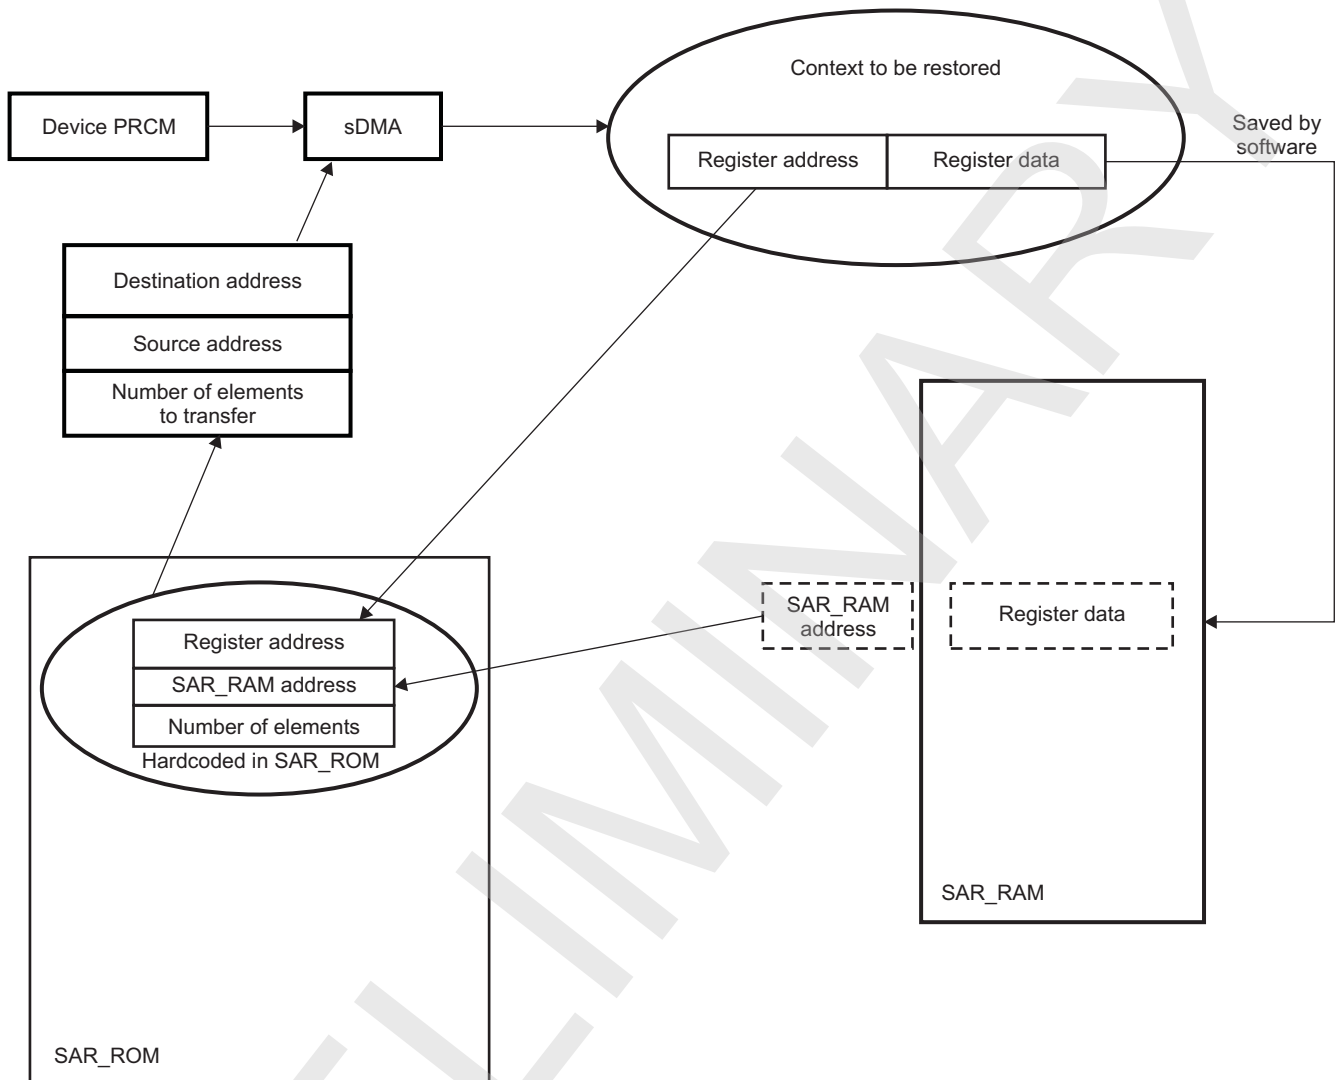

---

### 16.4.21 Auto-Restore Feature

The auto-restore feature is introduced mainly to accelerate the restore process, which otherwise is complex as well as time and resource consuming. In many system applications, it is required that the modem wake up and use only a few modules to wake up, without the main MPU (Cortex-A9 MPU) intervention. The MPU still might be in OFF mode; however, some modules might need to come out of OFF mode. The sDMA can be used to restore the register contents of these modules. The auto-restore feature consists in saving the registers data into a memory (SAR RAM sitting in the WKUP domain) that remains powered even during OFF-mode then it consists in retrieving automatically data when returning from OFF-mode.

The restore feature is enabled by default and cannot be disabled.

Figure 16-13 shows an overview of the save and restore mechanism using SAR RAM and SAR ROM.

**Figure 16-13. Save and Restore Mechanism Overview Using SAR RAM and SAR ROM**

dma-014

#### 16.4.21.1 Save Process

The save process is done entirely by software; the sDMA module normally is not involved. The software must save the data to be restored in a dedicated location in SAR RAM. To reduce the save sequence execution time, the sDMA can be used with linked-list descriptors. These save descriptors are symmetrical with regards to descriptors that lay in the SAR ROM.

The register content to be saved can be the register value before going into OFF-mode or a value that is required on wake up. This means that the restored register value can be different from the last value of the register before going into OFF-mode.

The following registers are impacted:

- CM1 and CM2 configuration  
Bits 0 of the CM\_SHADOW\_FREQ\_CONFIG1 register and the CM\_SHADOW\_FREQ\_CONFIG2 register are self-clearing and must be set at restore time. Thus, these data must always be overwritten in the SAR RAM.
- Because USBHOSTHS and USBTLL restore needs a particular sequencing, the software must overwrite data read from the following registers implied in phase2a and phase 2b:
  - **CM\_L3INIT\_HSUSBHOST\_CLKCTRL\_RESTORE**

- CM\_L3INIT\_HSUSBTLL\_CLKCTRL\_RESTORE
- CM\_SDMA\_STATICDEP\_RESTORE

The USBHOSTHS and USBTLL modules must be put in a particular mode when saving (and restoring) their context. In the case of context saving, the software must follow the following sequence:

- Configure the L3INIT clock domain to SW\_WKUP to ensure module transitions.
- Disable both modules.
- Assert the SAR\_MODE pins.
- Enable back both modules. Optional clocks must be kept gated.
- Save both modules context.
- Disable both modules.
- Deassert SAR\_MODE pins.
- At this point, the software might enable back both modules and get out L3INIT clock domain from the SW\_WKUP state.

### 16.4.21.2 Restore Process

As explained earlier, every time modem wakes up, the MPU must not necessarily wake up. This needs an automated way of restore. E.g .when mobile is in roaming, and not in active use, it needs to change base stations. For this task, the MPU need not wake up, only a few peripherals/subsystems need to be in ON mode. Before executing any task, we need to restore their register contents.

#### 16.4.21.2.1 PRCM and sDMA interaction During Restore Phase

Restore is performed during three phases. At the end of each phase, the sDMA stops and waits for the PRCM to perform the next phase transfer. For more information, see the *Device Off Mode Wake-Up Sequences* section in [Chapter 3, Power, Reset and Clock Management](#).

#### 16.4.21.2.2 sDMA Descriptors Description

The restore phase is automatically done by the sDMA. The sDMA gets the register address (**Destination address**), the **number of elements** to transfer and the address of the data to transfer (**Source address**) from SAR ROM. As mentioned previously the register data is stored in the SAR RAM.

SAR ROM content:

The SAR ROM contains two types of descriptors that the DMA-4 should use:

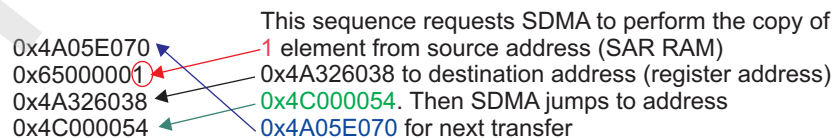

- Type-1 descriptors
- Type-3 descriptors with both source and destination address update

**Type-1** descriptor (48 bytes) is to be used at the beginning of each phase. Indeed, in addition of source and destination address and number of elements, it contains the required data that initializes the sDMA. [Table 16-13](#) shows the Type-1 descriptor structure.

**Type-3** descriptors (16 bytes) are to be used for subsequent sDMA transfers and contain mainly source and destination address and number of elements. [Table 16-16](#) shows the Type-3 descriptor structure.

[Figure 16-14](#) shows an example of SAR ROM code (Type-3 Descriptor):

**Figure 16-14. Type-3 SAR ROM Code Example**

dma-015

[Figure 16-15](#) shows an example of Last DMA transfer (Type-3 Descriptor):

To indicate to the DMA that this is the last transfer, then the next descriptor address must be set to 0xFFFFFFF0 as in the example below :

**Figure 16-15. Type-3 SAR ROM Last transfer Example**

dma-016

### 16.4.21.3 SAR RAM

The SAR RAM contains the **data** which needs to be maintained during OFF-mode. The SAR RAM is split into 3 banks:

**Table 16-18. SAR RAM Allocation**

Access Mode	Bank	Address Range
public	1 (SAR_RAM_1)	0x4A32_6000 0x4A32_6FFF (4kB)
public, for IO Pad	2 (SAR_RAM_2)	0x4A32_7000 0x4A32_73FF (1kB)
public	3 (SAR_RAM_3)	0x4A32_8000 0x4A32_87FF (2kB)

### 16.4.21.4 SAR ROM

The SAR ROM contains the list of registers that need to be saved before OFF-mode and so restored after OFF-mode and contains also the location where the register data is stored in SAR RAM. The SAR ROM start address is 0x4A05\_E000.

When exiting OFF-mode, PRCM automatically redirects sDMA to address:

- 0x4A05\_E000 for phase 1 (in SAR ROM)
- 0x4A05\_E030 for phase 2a (in SAR ROM)
- 0x4A05\_E060 for phase 2b (in SAR ROM)

The SAR ROM is build so that sDMA will perform all the transfers for each phase. At the end of each phase, sDMA will stop. PRCM will then request to perform the next phase transfer depending on wakeup source.

#### Remarks:

- Phase 1 is always to happen, the RESTORE mechanism is enabled by default and can not be disabled.
- Phase 2 (2a and 2b) is to happen depending on the wake-up source from OFF-mode. Phase 2 will not be performed if C2C is the wake-up source, but it will be performed for all the other wake-up sources. So it is mandatory to correctly fill the SAR RAM locations used for USB restore, even USB is not used because the restore sequence will happen.
- USB host RESTORE is to be performed before USB TLL RESTORE

**NOTE:** Some consecutive address registers cannot be saved/restored with burst. This is the case for:

- CLK1\_DSS\_BW\_REGULATOR.L3\_BW\_R\_BANDWIDTH and CLK1\_DSS\_BW\_REGULATOR.L3\_BW\_R\_WATERMARK registers
- CLK2\_XXX\_BW\_REGULATOR.L3\_BW\_R\_BANDWIDTH and CLK2\_XXX\_BW\_REGULATOR.L3\_BW\_R\_WATERMARK registers, where XXX stands for ISS, IVAHD and SGX.

To avoid sDMA transfer failure, the transfer of the above register is performed using a single sDMA transfer.

### 16.4.21.5 SAR RAM Memory Allocation Reserved for Save and Restore

The memory size of the SAR RAM reserved for the Save and Restore mechanism is:

- 57% (2344 bytes) reserved for the SAR mechanism from SAR\_RAM\_1. The whole SAR\_RAM\_1 size is 4KB.
- 40% (408 bytes) reserved for the SAR mechanism from SAR\_RAM\_2. The whole SAR\_RAM\_2 size is 1KB.
- 51% (1052 bytes) reserved for the SAR mechanism from SAR\_RAM\_3. The whole SAR\_RAM\_3 size is 2KB.

The free part of the SAR RAM can be used by the user software to store any data that needs to be in always-on memory.

#### 16.4.21.6 Register Mapping in SAR RAM

Table 16-19 shows the SAR\_RAM\_1 memory mapping.

**Table 16-19. SAR\_RAM\_1 Memory Mapping**

Order	Register Name	Register Start Addr	Register End Addr	Size	SAR_RAM_1 Addr
1	EMIF1.EMIF_SDRAM_CONFIG	0x4C000008		4	0x4A326000

## 16.5 sDMA Basic Programming Model

### 16.5.1 Setup Configuration

After a hardware reset, program all fields in the logical channel registers to default values for any channels used, because most fields are undefined following reset.

Before programming any DMA transfers, the priority arbitration rate and the maximum FIFO depth must be configured through the [DMA4\\_GCR](#) register, and any required interrupts must be enabled through the [DMA4\\_IRQENABLE\\_Lj](#) registers and the logical channel [DMA4\\_CICRi](#) registers.

Software clears the [DMA4\\_CSRi](#) register and the IRQSTATUS bit for the different interrupt lines before enabling the channel.

### 16.5.2 Software-Triggered (Nonsynchronized) Transfer

To program a software-triggered DMA transfer:

1. Configure the transfer parameters in the logical DMA channel registers:

- [DMA4\\_CSDPi](#):
  - Transfer ES (8 bits, 16 bits, or 32 bits) in DMA register bits [DMA4\\_CSDPi\[1:0\]](#)
  - Read and write port access types (single/burst), DMA register bits [DMA4\\_CSDPi\[8:7\]](#) and [DMA4\\_CSDPi\[15:14\]](#)
  - Source and destination endianism, DMA register bits [DMA4\\_CSDPi\[21\]](#) and [DMA4\\_CSDPi\[19\]](#)
  - Write mode (posted or nonposted) and DMA register bits [DMA4\\_CSDPi\[17:16\]](#)
  - Source or destination packed or nonpacked (if the ES is less than the read/write port size), DMA register bits [DMA4\\_CSDPi\[6\]](#) and [DMA4\\_CSDPi\[13\]](#)
- [DMA4\\_CENi](#): EN
- [DMA4\\_CFNi](#): FN per transfer block
- [DMA4\\_CSSAi](#) and [DMA4\\_CDSAi](#): Source and destination start address (aligned with transfer ES)
- [DMA4\\_CCRi](#):
  - Read and write port addressing modes, DMA register bits [DMA4\\_CCRi\[13:12\]](#) and

- DMA4\_CCRi[15:14]
    - Priority bit for both read and write ports, DMA register bits DMA4\_CCRi[6] and DMA4\_CCRi[26]
    - DMA request number (set to 0 for a software-triggered transfer) and DMA register bits DMA4\_CCRi[4:0] = 0 and DMA4\_CCRi[20:19] = 0
  - DMA4\_CSEIi, DMA4\_CSFli, DMA4\_CDEIi, and DMA4\_CDFIi: Source and destination element and frame indexes (depending on addressing mode)
2. Start the transfer through the enable bit in the channel DMA4\_CCRi register and DMA register bit DMA4\_CCRi[7]

The example below perform a DMA transfer on channel 10 of a 240\*160 picture from RAM to RAM (0x80C00000 to 0x80F00000) :

```

UWORD32 RegVal = 0;
DMA4_t *DMA4;
DMA4 = (DMA4_t *)malloc(sizeof(DMA4_t));
/* Init. parameters */
DMA4->DataType = 0x2; // DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0; // DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0; // DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21]
DMA4->DestinationEndianism = 0; // DMA4_CSDPi[19]

```

```

RegVal = ((RegVal & ~(0x1 << 26)) | (DMA4->WritePriority << 26));
RegVal&= 0xFFCFFFE0 ;
// Write CCR
DMA4_CCR_CH10 = RegVal;
/* f)- Set the source element index CSEI[15:0]*/
DMA4_CSEI_CH10 = DMA4->SourceElementIndex;
/* g)- Set the source frame index CSFI[15:0]*/
DMA4_CSFI_CH10 = DMA4->SourceFrameIndex ;
/* h)- Set the destination element index CDEI[15:0]*/
DMA4_CDEI_CH10 = DMA4->DestinationElementIndex;
/* i)- Set the destination frame index CDFI[31:0]*/
DMA4_CDFI_CH10 = DMA4->DestinationFrameIndex;
/* 2) Start the DMA transfer by Setting the enable bit CCR[7]=1 */
/*-----*/
//write enable bit
DMA4_CCR_CH10 |= 1 << 7; /* start */

```

### 16.5.3 Hardware-Synchronized Transfer

To monitor a hardware synchronized DMA transfer, initialize the [DMA4\\_CDACi](#) register before the software enable.

To configure an LCh to synchronize by element, packet, frame, or block, the frame synchronization [DMA4\\_CCRi\[5\]](#) FS bit and the block synchronization [DMA4\\_CCRi\[18\]](#) BS bit register must be programmed. For all the following synchronized transfers (element, packet, frame or block synchronized transfers) User must set first : [DMA4\\_CCRi\[24\]](#) SEL\_SRC\_DST\_SYNC to 1 when the source triggers on the DMA request and [DMA4\\_CCRi\[24\]](#) SEL\_SRC\_DST\_SYNC to 0 when the Destination triggers on the DMA request. Note: User must take care when setting the [DMA4\\_CCRi\[23\]](#) PREFETCH bit it is in conjunction with [DMA4\\_CCRi\[24\]](#) SEL\_SRC\_DST\_SYNC bit.

- To configure an LCh to transfer one element per DMA request:
  1. Set the number of DMA request associated to the current LCH in the [DMA4\\_CCRi\[20:19\]](#) SYNCHRO\_CONTROL\_UPPER and [DMA4\\_CCRi\[4:0\]](#) SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the [DMA4\\_CSDPi\[1:0\]](#) DATA\_TYPE bit field.
  3. Set the Read Port access type (single or burst access) in the [DMA4\\_CSDPi\[8:7\]](#) SRC\_BURST\_EN bit field.
  4. Set the Write Port access type (single or burst access) in the [DMA4\\_CSDPi\[15:14\]](#) DST\_BURST\_EN bit field.
  5. Set the Read Port addressing mode in the [DMA4\\_CCRi\[13:12\]](#) SRC\_AMODE bit field.
  6. Set the Write Port addressing mode in the [DMA4\\_CCRi\[15:14\]](#) DST\_AMODE bit field.
  7. Set the Read start address in the [DMA4\\_CSSAi\[31:0\]](#) SRC\_START\_ADRS bit field.
  8. Set the Write start address in the [DMA4\\_CDSAi\[31:0\]](#) DST\_START\_ADRS bit field.
  9. Set both FS and BS to 0 in [DMA4\\_CCRi\[5\]](#) FS and [DMA4\\_CCRi\[18\]](#) BS.
  10. Set to 1 the channel enable bit [DMA4\\_CCRi\[7\]](#) EN.
- To configure an LCh to transfer one frame per DMA request:
  1. Set the number of DMA request associated to the current LCH in the [DMA4\\_CCRi\[20:19\]](#) SYNCHRO\_CONTROL\_UPPER and [DMA4\\_CCRi\[4:0\]](#) SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the [DMA4\\_CSDPi\[1:0\]](#) DATA\_TYPE bit field.
  3. Set the number of element per frame in the [DMA4\\_CENi\[23:0\]](#) CHANNEL\_ELMNT\_NBR bit field.
  4. Set the Read Port access type (single or burst access) in the [DMA4\\_CSDPi\[8:7\]](#) SRC\_BURST\_EN bit field.
  5. Set the Write Port access type (single or burst access) in the [DMA4\\_CSDPi\[15:14\]](#) DST\_BURST\_EN bit field.
  6. Set the Read Port addressing mode in the [DMA4\\_CCRi\[13:12\]](#) SRC\_AMODE bit field.
  7. Set the Write Port addressing mode in the [DMA4\\_CCRi\[15:14\]](#) DST\_AMODE bit field.
  8. Set the Read start address in the [DMA4\\_CSSAi\[31:0\]](#) SRC\_START\_ADRS bit field.
  9. Set the Write start address in the [DMA4\\_CDSAi\[31:0\]](#) DST\_START\_ADRS bit field.

10. Set FS to 1 and BS to 0, respectively, in `DMA4_CCRi[5]` FS and `DMA4_CCRi[18]` BS.
11. Set to 1 the channel enable bit `DMA4_CCRi[7]` EN.
- To configure an LCh to transfer one block per DMA request:
  1. Set the number of DMA request associated to the current LCH in the `DMA4_CCRi[20:19]` SYNCHRO\_CONTROL\_UPPER and `DMA4_CCRi[4:0]` SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the `DMA4_CSDPi[1:0]` DATA\_TYPE bit field.
  3. Set the number of element per frame in the `DMA4_CENi[23:0]` CHANNEL\_ELMNT\_NBR bit field.
  4. Set in the `DMA4_CFNi[15:0]` CHANNEL\_FRAME\_NBR bit field the number of frame (transfers), to take place before the LCH gets disabled.
  5. Set the Read Port access type (single or burst access) in the `DMA4_CSDPi[8:7]` SRC\_BURST\_EN bit field.
  6. Set the Write Port access type (single or burst access) in the `DMA4_CSDPi[15:14]` DST\_BURST\_EN bit field.
  7. Set the Read Port addressing mode in the `DMA4_CCRi[13:12]` SRC\_AMODE bit field.
  8. Set the Write Port addressing mode in the `DMA4_CCRi[15:14]` DST\_AMODE bit field.
  9. Set the Read start address in the `DMA4_CSSAi[31:0]` SRC\_START\_ADRS bit field.
  10. Set the Write start address in the `DMA4_CDSAi[31:0]` DST\_START\_ADRS bit field.
  11. Set FS to 0 and BS to 1, respectively, in `DMA4_CCRi[5]` FS and `DMA4_CCRi[18]` BS.
  12. Set to 1 the channel enable bit `DMA4_CCRi[7]` EN.
- To configure an LCh to transfer one packet per DMA request:
  1. Set the number of DMA request associated to the current LCH in the `DMA4_CCRi[20:19]` SYNCHRO\_CONTROL\_UPPER and `DMA4_CCRi[4:0]` SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the `DMA4_CSDPi[1:0]` DATA\_TYPE bit field.
  3. Set the number of elements per packet to transfer: If the packet requestor is in the source, set `DMA4_CCRi [24]` SEL\_SRC\_DST\_SYNC to 1 and set the packet element number in the `DMA4_CSFli` register and set the addressing mode of source to constant addressing in `DMA4_CCRi[13:12]` SRC\_AMODE bit field; else, if the packet requestor is in the destination, set the `DMA4_CCRi[24]` SEL\_SRC\_DST\_SYNC to 0 and set the packet element number in the `DMA4_CDFli` register and set the addressing mode of destination to constant addressing in `DMA4_CCRi[15:14]` DST\_AMODE bit field.
  4. Set the number of elements per frame in the `DMA4_CENi[23:0]` CHANNEL\_ELMNT\_NBR bit field.
  5. Set in the `DMA4_CFNi[15:0]` CHANNEL\_FRAME\_NBR bit field the number of frames (transfers), to take place before the LCH gets disabled.
  6. Set the element number in the packet in the `DMA4_CSFli[15:0]` PKT\_ELNT\_NBR, if constant addressing or post-incremented addressing modes are used in the source side. However, the number of element in the packet is set in the `DMA4_CDFli[15:0]` PKT\_ELNT\_NBR if constant addressing mode is used in the destination side.
  7. Set the Read Port access type (single or burst access) in the `DMA4_CSDPi[8:7]` SRC\_BURST\_EN bit field.
  8. Set the Write Port access type (single or burst access) in the `DMA4_CSDPi[15:14]` DST\_BURST\_EN bit field.
  9. Set the Read Port addressing mode in the `DMA4_CCRi[13:12]` SRC\_AMODE bit field.
  10. Set the Write Port addressing mode in the `DMA4_CCRi[15:14]` DST\_AMODE bit field.
  11. Set the Read start address in the `DMA4_CSSAi[31:0]` SRC\_START\_ADRS bit field.
  12. Set the Write start address in the `DMA4_CDSAi[31:0]` DST\_START\_ADRS bit field.
  13. Set FS to 1 and BS to 1, respectively, in `DMA4_CCRi[5]` FS and `DMA4_CCRi[18]` BS.
  14. Set to 1 the channel enable bit `DMA4_CCRi[7]` EN.

---

**NOTE:** It is possible to stop a transfer by disabling the channel by resetting the `DMA4_CCRi[7]` ENABLE bit.

---

### 16.5.4 Synchronized Transfer Monitoring Using CDAC

The `DMA4_CDACi` register is writable and non-initialized (value undefined). It can be initialized to monitor a transfer by applying the following programming model:

1. Write 0 in the `DMA4_CDACi` register.
2. Enable the channel.
3. If a time-out occurs, read `DMA4_CDACi` register.
4. If `DMA4_CDACi` != 0 (it is the value configured in `DMA4_CDACi`):
 

This indicates that the corresponding transfer has started. User can then rely on `DMA4_CCENi` and `DMA4_CCFNi` element and frame counters.

Else, if `DMA4_CDACi` = 0 (it is the value configured in the `DMA4_CDACi`):

This indicates that the corresponding transfer did not start.

### 16.5.5 Concurrent Software and Hardware Synchronization

This section describes thread allocation only; it does not describe the entire transfer. Because synchronized transfers are latency critical, you must allocate a thread at least on the synchronized target side.

Even for multiple concurrent channels, thread reservation ensures that when a hardware DMA request arrives, the read/write scheduler finds available thread(s) to initiate a channel schedule and issue a read/write transaction.

Consider six concurrent channels:

- Channels 0, 1, 2, and 3 are dedicated to memory-memory transfer; they are software triggered and not synchronized.
- Channel 4 is dedicated to memory-peripheral transfer, hardware triggered, and synchronized on the write side.
- Channel 5 is dedicated to peripheral-memory transfer, hardware triggered, and synchronized on the read side.

To perform thread reservation:

1. Allow thread reservation for priority channel 4 and channel 5:
 

Reserve one thread (Read ThreadID 0) on the read port and one thread (Write ThreadID 0) on the write port: set the `DMA4_GCR[13:12]` `HI_THREAD_RESERVED` bit field to 0x1.
2. Specify channel priority:
 

Channel 4 is a write high priority channel: set `DMA4_CCRi[26]` `WRITE_PRIORITY` = 1.

Channel 5 is a read high priority channel: set `DMA4_CCRi[6]` `READ_PRIORITY` = 1.

### 16.5.6 Chained Transfer

A chained DMA transfer can be programmed as follows:

1. Configure the transfer parameters for each logical DMA channel in the chain as in step 1 for either the synchronized or non-synchronized transfers describe in [Section 16.5.5, Concurrent Software and Hardware Synchronization](#).
2. For each channel in the chain, configure the `DMA4_CLNK_CTRLi` register as follows:
  - Next logical DMA channel number (for a looping chained transfer link last channel to first channel number), in the `DMA4_CLNK_CTRLi[4:0]` `NEXTLCH_ID` bit field.
  - Include the logical channel to the chain and enable link by setting the `DMA4_CLNK_CTRLi[15]` `ENABLE_LNK` bit.
  - For a non-looping chain, the last logical channel in the chain must have the `DMA4_CLNK_CTRLi[15]` `ENABLE_LNK` bit set to 0 to indicate the end of the chain.
3. Enable the transfer through the enable bit in the first logical channel `DMA4_CCRi[7]` `ENABLE` bit. All other channels in the chain must be disabled. Each channel is enabled automatically in turn when the previous logical channel transfer completes. A non-synchronized transfer starts immediately; a hardware-synchronized transfer starts when the DMA request line corresponding to the first DMA channel in the chain is asserted.

To stop a looping chained transfer, disable the `DMA4_CLNK_CTRLi[15] ENABLE_LNK` bit (by setting it to 0x0), of the final channel transfer.

In the RAM-to-RAM copy example, to copy in loop, it is possible to link channel 10 on itself. The following line can be added in the channel configuration:

```
/* g) Set link for loop */
DMA4_CLNK_CTRL_CH10 = 0x0000800A;
```

### 16.5.7 90-Degree Clockwise Image Rotation

The 90-degree clockwise image rotation example described in [Section 16.4.5, Addressing Modes](#), can be programmed as follows:

1. Configure the transfer parameters in the logical DMA channel registers:

- **DMA4\_CSDPi:**
  - Transfer ES = 32-bit (32 bpp), `DMA4_CSDPi[1:0] DATA_TYPE` bit field
  - Read and write port access types = maximum burst size supported by memory device, `DMA4_CSDPi[8:7] SRC_BURST_EN` and `DMA4_CSDPi[15:14] DST_BURST_EN` bit fields
  - Source and destination endianness, `DMA4_CSDPi[21] SRC_ENDIAN` and `DMA4_CSDPi[19] DST_ENDIAN` bits
  - Write mode = posted with last element nonposted, `DMA4_CSDPi[17:16] WRITE_MODE` bit field
  - Source and destination packed = Yes (although destination writes do not benefit because  $EI > 1$ ), `DMA4_CSDPi[6] SRC_PACKED` and `DMA4_CSDPi[13] DST_PACKED` bits
- **DMA4\_CENi:** EN = 240
- **DMA4\_CFNi:** FN per transfer block = 160
- **DMA4\_CSSAi:** Source start address = 0x100000
- **DMA4\_CDSAi:** destination start address = 0x20013E
- **DMA4\_CCRi:**
  - Read and write port addressing modes = double-index addressing mode for both or post-increment addressing on source and double-index addressing on destination, `DMA4_CCRi[13:12] SRC_AMODE` and `DMA4_CCRi[15:14] DST_AMODE` bit fields
  - Low or high priority, `DMA4_CCRi[6] READ_PRIORITY` bit
  - DMA request number = 0 (for software-triggered transfer), `DMA4_CCRi[4:0] SYNCHRO_CONTROL` and `DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER` bit fields
- **DMA4\_CSEIi:** Source EI = 1
- **DMA4\_CSFII:** Source frame index = 1
- **DMA4\_CDEIi:** destination EI = 637
- **DMA4\_CDFII:** destination frame index = 152967

2. Start the transfer through the enable bit in the channel `DMA4_CCRi` register.

The following parameters are used to perform this rotation from 0x80C00000 RAM address to 0x80F00000, with the same code used in [Section 16.5.2, Software-Triggered \(Nonsynchronized\) Transfer](#).

```
/* Init. parameters */
DMA4->DataType = 0x2; // DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0x3; // DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0x3; // DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21]
DMA4->DestinationEndianness = 0; // DMA4_CSDPi[19]
DMA4->WriteMode = 0x2; // DMA4_CSDPi[17:16]
DMA4->SourcePacked = 0x1; // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0x1; // DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; // DMA4_CENi
DMA4->NumberOfFramePerTransferBlock = 160; // DMA4_CFNi
DMA4->SourceStartAddress = 0x80C00000; // DMA4_CSSAi
DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSAi
DMA4->SourceElementIndex = 1; // DMA4_CSEIi
DMA4->SourceFrameIndex = 1; // DMA4_CSFII
DMA4->DestinationElementIndex = 637; // DMA4_CDEIi
DMA4->DestinationFrameIndex = -152967; // DMA4_CDFII
DMA4->ReadPortAccessMode = 0x3; // DMA4_CCRi[13:12]
DMA4->WritePortAccessMode = 0x3; // DMA4_CCRi[15:14]
DMA4->ReadPriority = 0; // DMA4_CCRi[6]
```

```
DMA4->WritePriority = 0; // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; // DMA4_CCRi[4:0]
DMA4->WriteRequestNumber = 0; // DMA4_CCRi[20:19]
```

### 16.5.8 Graphic Operations

- Transparent copy:
  1. Set the [DMA4\\_CCRi\[17\]](#) TRANSPARENT\_COPY\_ENABLE bit to 1
  2. Set the [DMA4\\_CCRi\[16\]](#) CONST\_FILL\_ENABLE bit to 0
  3. Set the value of the key color in the [DMA4\\_COLORi\[15:0\]](#) COLOR\_KEY bit field

To perform this graphic operation, the following lines can be added to the example of [Section 16.5.2, Software-Triggered \(Nonsynchronized\) Transfer](#).

```
DMA4_CCR_CH10 &= ~(0x1 << 16);
DMA4_CCR_CH10 |= 0x1 << 17;
DMA4_COLOR_CH10 = 0x00000003;
```

- Solid Color fill:
  1. Set the [DMA4\\_CCRi\[16\]](#) CONST\_FILL\_ENABLE bit to 1
  2. Set the [DMA4\\_CCRi\[17\]](#) TRANSPARENT\_COPY\_ENABLE bit to 0
  3. Set the value of key the color in the [DMA4\\_COLORi\[15:0\]](#) SOLID\_COLOR bit field

To perform this graphic operation, the following lines can be added to the example of [Section 16.5.2, Software-Triggered \(Nonsynchronized\) Transfer](#).

```
DMA4_CCR_CH10 &= ~(0x1 << 17);
DMA4_CCR_CH10 |= 0x1 << 16;
DMA4_COLOR_CH10 = 0x00000003;
```

### 16.5.9 Linked-List Programming Guidelines

- With the exception of the [DMA4\\_CCRi\[7\]](#) ENABLE bit and the [DMA4\\_CDPi\[7\]](#) PAUSE\_LINK\_LIST bit during a linked-list transfer (descriptor load phase or data load phase), avoid programming any register through the configuration port.
- Before enabling any linked-list transfer, ensure that all global registers and all registers in the descriptor are initialized. Some static channel registers (registers that are not updated by the descriptor to be loaded) must also be initialized correctly:
  - For type 2, the following registers must be initialized with consistent values:
    - All global registers
    - [DMA4\\_CCRi](#)
    - [DMA4\\_CSDPi](#)
    - [DMA4\\_CLNK\\_CTRLi](#)
  - For type 3, the following registers must be initialized with consistent values:
    - All global registers
    - [DMA4\\_CCRi](#)
    - [DMA4\\_CSDPi](#)
    - [DMA4\\_CLNK\\_CTRLi](#)
    - [DMA4\\_CICRi](#)
    - [DMA4\\_CFNi](#)
- In case of a linked list with descriptor types 2 and 3, the content of the [DMA4\\_CCRi](#) register must not change during super-block life.
- The PAUSE\_LINK\_LIST bit must not be set in the initialization phase.

## 16.6 sDMA Register Manual

### 16.6.1 sDMA Instance Summary

**Table 16-22. sDMA Instance Summary**

Module Name	Base Address	Size
sDMA	0x4A05 6000	4KB

### 16.6.2 sDMA Registers

#### 16.6.2.1 sDMA Register Summary

Index  $i$  represents the logical channel number (where  $i = 0$  to 31). The offset address for some registers is calculated from channel  $c$  number. For example, register DMA4\_CCR10 (channel 10) has an offset address of  $10 \times 0x60 = 0x3C0$ , and so a physical address of  $0x4A05\ 6080 + 0x3C0 = 0x4A05\ 6440$ .

Index  $j$  represents the interrupt line number (where  $j = 0$  to 3). The offset address for some registers is calculated from channel  $c$  number. For example, register DMA4\_IRQSTATUS\_L3 (line 3) has an offset address of  $3 \times 0x4 = 0xC$ , and so a physical address of  $0x4A05\ 6008 + 0xC = 0x4A05\ 6014$ .

**Table 16-23. sDMA Registers Mapping Summary**

### 16.6.2.2 sDMA Register Description

**NOTE:** Some registers have no reset value (marked with -) because of hardware implementation in memory. Software must ensure the correct programming of these registers, if needed.

Shadow registers are used to read run-time registers such as CCEN, CCFN, CDAC, and CSAC. Typically, when accessed in 8-bit or 16-bit access for two consecutive accesses, the value of the previous registers can change. A shadow register holds the entire value to let the next access recover the remaining 24 bits or 16 bits.

For non-32-bit transactions, start reading or writing from the LSByte first to enable the register update. There is no issue for 32-bit read-write transactions.

RESERVED								ARBITRATION_RATE								HI_LO_FIFO_BUDGET		HI_THREAD_RESERVED		RESERVED						MAX_CHANNEL_FIFO_DEPTH							
CHANNEL_ID_GATE																																	

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x00
24	CHANNEL_ID_GATE	Gates the Channel ID bus monitoring on both Read and Write ports 0x0: Gates the Channel ID qualifiers on both Read and Write Ports 0x1: Does not gate the Channel ID qualifiers on both Read and Write Ports	RW	0x0
23:16	ARBITRATION_RATE	Arbitration switching rate between prioritized and regular channel queues	RW	0x01
15:14	HI_LO_FIFO_BUDGET	Allow to have a separate Global FIFO budget for high and low priority channels. For Hi priority Channel: (Per_channel_Maximum FIFO depth + 1) x Number of active High priority Channel =< High Budget FIFO For Low priority channel: (Per_channel_Maximum FIFO depth + 1) x Number of active Low priority Channel =< Low Budget FIFO 0x0: no fixed budget for neither higher nor lower priority channel 0x1: 75% of FIFO for low priority and 25% for high priority channels 0x2: 25% of FIFO for low priority and 75% for high priority channels 0x3: 50% of FIFO for low priority and 50% for high priority channels	RW	0x0
13:12	HI_THREAD_RESERVED	Allow thread reservation for high priority channel on both read and write ports. 0x0: No ThreadID is reserved on the Read Port for high priority channels. No ThreadID is reserved on the Write Port for high priority channels. 0x1: Read Port ThreadID 0 is reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x2: Read port ThreadID 0 and ThreadID 1 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x3: Read PortThreadID 0, ThreadID 1 and ThreadID 2 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels.	RW	0x0
11:8	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
7:0	MAX_CHANNEL_FIFO_DEPTH	Maximum FIFO depth allocated to one logical channel. Maximum FIFO depth can not be 0x0. It should be at least 0x1 or greater. Note that If channel limit is less than destination burst size enough data will not be accumulated in the data FIFO and it will never be sent out on the WR port. The burst size should be less than the FIFO limit specified in this bit field.	RW	0x10

RESERVED	RESERVED	RESERVED	RESERVED	RESERVED	WRITE_PRIORITY	BUFFERING_DISABLE	SEL_SRC_DST_SYNC	PREFETCH	SUPERVISOR	RESERVED	SYNCHRO_CONTROL_UPPER	BS	TRANSPARENT_COPY_ENABLE	CONST_FILL_ENABLE	DST_AMODE	SRC_AMODE	RESERVED	WR_ACTIVE	RD_ACTIVE	SUSPEND_SENSITIVE	ENABLE	READ_PRIORITY	FS	SYNCHRO_CONTROL	SYNCHRO_CONTROL	SYNCHRO_CONTROL	SYNCHRO_CONTROL	SYNCHRO_CONTROL	SYNCHRO_CONTROL	SYNCHRO_CONTROL	SYNCHRO_CONTROL

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0
29:27	RESERVED	Reserved for non-GP devices	RW	0x0
26	WRITE_PRIORITY	Channel priority on the Write side  0x0: Channel has low priority on the Write side during the arbitration process  0x1: Channel has high priority on Write sided during the arbitration process	RW	0

Bits	Field Name	Description	Type	Reset
25	BUFFERING_DISABLE	This bit allows to disable the default buffering functionality when transfer is source synchronized.  0x0: buffering is enable across element/packet when source is synchronized to element, packet, frame or bolcks  0x1: buffering is disabled across element/packet when source is synchronized to element, packet, frame or bolcks	RW	-
24	SEL_SRC_DST_SYNC	Specifyes that element, packet, frame or block transfer (depending on CCR.bs and CCR.fs) is triggered by the source or the destination on the DMA request  0x0: Transfer is triggered by the destination. If synch on packet the packet element number is specified in the CDFI register  0x1: Transfer is triggered by the source. If synchronized on packet the packet element number is specified in the CSFI register	RW	-
23	PREFETCH	Enables the prefetch mode  0x0: Prefetch mode is disabled. When Sel_Src_Dst_Sync=1 transfers are buffred and pipelined between DMA requests  0x1: Prefetch mode is enabled. Prefetch mode is active only when destination is synchronised. It is SW user responsibility not to have at the same time Prefetch=1 when Sel_Src_Dst_Sync=1. This mode is not supported	RW	0
22	SUPERVISOR	Enables the supervisor mode  0x0: Supervisor mode is disabled  0x1: Supervisor mode is enabled	RW	0
21	RESERVED	Reserved for non GP devices	RW	0
20:19	SYNCHRO_CONTROL_UPPER	Channel Synchronization control upper (used in conjunction with the 5 bits of synchro channel <a href="#">DMA4_CCRi[4:0]</a> ) Used in conjunction, as two msb, with the five bits of the synchro channel bit field.	RW	0b00
18	BS	Block synchronization This bit used in conjunction with the fs to see how the DMA request is serviced in a synchronized transfer	RW	-
17	TRANSPARENT_COPY_ENABLE	Transparent copy enable  0x0: Transparent copy mode is disabled  0x1: Transparent copy mode is enabled	RW	-
16	CONST_FILL_ENABLE	Constant fill enable  0x0: Constant fill mode is disabled  0x1: Constant fill mode is enabled	RW	0
15:14	DST_AMODE	Selects the addressing mode on the Write Port of a channel.  0x0: Constant address mode  0x1: Post-incremented address mode  0x2: Single index address mode  0x3: Double index address mode	RW	0bxx
13:12	SRC_AMODE	Selects the addressing mode on the Read Port of a channel.  0x0: Constant address mode  0x1: Post-incremented address mode  0x2: Single index address mode  0x3: Double index address mode	RW	0bxx
11	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0

Bits	Field Name	Description	Type	Reset
10	WR_ACTIVE	Indicates if the channel write context is active or not Read 0x0: Channel is not active on the write port Read 0x1: Channel is currently active on the write port	R	0
9	RD_ACTIVE	Indicates if the channel read context is active or not Read 0x0: Channel is not active on the read port Read 0x1: Channel is currently active on the read port	R	0
8	SUSPEND_SENSITIVE	Logical channel suspend enable bit 0x0: The channel ignores the MSuspend even if EMUFree is set to 0. 0x1: If EMUFree is set to 0 and MSuspend comes in then all current OCP services (single transaction or burst transaction as specified in the corresponding CSDP register) have to be completed before stopping processing any more transactions	RW	0
7	ENABLE	Logical channel enable. It is SW responsibility to clear the CSR register and the IRQSTATUS bit for the different interrupt lines before enabling the channel. 0x0: The logical channel is disabled 0x1: The logical channel is enabled	RW	0
6	READ_PRIORITY	Channel priority on the read side 0x0: Channel has low priority on the Read side during the arbitration process 0x1: Channel has high priority on read sided during the arbitration process	RW	0
5	FS	Frame synchronization This bit used in conjunction with the BS to see how the DMA request is serviced in a synchronized transfer FS=0 and BS=0: An element is transferred once a DMA request is made. FS=0 and BS=1: An entire block is transferred once a DMA request is made. FS=1 and BS=0: An entire frame is transferred once a DMA request is made. FS=1 and BS=1: A packet is transferred once a DMA request is made. All these different transfers can be interleaved on the port with other DMA requests.	RW	-
4:0	SYNCHRO_CONTROL	Channel synchronization control This bit field used in conjunction with the second_level_synchro_control_upper (as two msb) 0000000 : 1s reserved for non synchronized LCH transfer xxxxxxx (from 1 to 127) There are 127 possible DMA request to assign to any LCH. <b>Note:</b> The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, DMA4_CCR[4:0] SYNCHRO_CONTROL must be set to 0x2 (DMA request number + 1).	RW	0b00000

<b>Address Offset</b>	0x0000 0084 + (0x60 * i)	<b>index:</b>	i = 0 to 31
<b>Physical Address</b>	See <a href="#">Table 16-23</a>	<b>Instance</b>	sDMA
<b>Description</b>	Channel Link Control Register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RESERVED																ENABLE_LNK	RESERVED										NEXTLCH_ID					

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0000
15	ENABLE_LNK	Enables or disable the channel linking.  0x0: Channel linking mode is disabled When set on the fly to 0 the current channel will complete the transfer and stops the chain linking  0x1: Channel linking mode is enabled. The logical channel defined in the NextLCH_ID is enabled at the end of the current transfer	RW	0
14:5	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x000

Bits	Field Name	Description	Type	Reset
4:0	NEXTLCH_ID	Defines the NextLCh_ID, which is used to build logical channel chaining queue.	RW	0bxxxxx

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x00000
14	SUPER_BLOCK_IE	Enables the end of super block interrupt	RW	-
13	RESERVED	Reserved for non-GP devices	RW	1
12	DRAIN_IE	Enables the end of draining interrupt	RW	0
11	MISALIGNED_ERR_IE	Enables the address misaligned error event interrupt 0x0: Disables the misaligned address error event interrupt 0x1: Enables the misaligned address error event interrupt	RW	-
10	SUPERVISOR_ERR_IE	Enables the supervisor transaction error event interrupt 0x0: Disables the supervisor transaction error event interrupt 0x1: Enables the supervisor transaction error event interrupt	RW	1
9	RESERVED	Reserved for non-GP devices	RW	1
8	TRANS_ERR_IE	Enables the transaction error event interrupt 0x0: Disables the transaction error event interrupt 0x1: Enables the transaction error event interrupt	RW	-

Bits	Field Name	Description	Type	Reset
7	PKT_IE	Enables the end of Packet interrupt 0x0: Disables the end of Packet transfer interrupt 0x1: Enables the end of Packet transfer interrupt	RW	-
6	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0
5	BLOCK_IE	Enables the end of block interrupt 0x0: Disables the end of block interrupt 0x1: Disables the end of block interrupt	RW	-
4	LAST_IE	Last frame interrupt enable (start of last frame) 0x0: Disables the last frame interrupt 0x1: Enables the last frame interrupt	RW	-
3	FRAME_IE	Frame interrupt enable (end of frame) 0x0: Disables the end of frame interrupt 0x1: Enables the end of frame interrupt	RW	-
2	HALF_IE	Enables or disables the half frame interrupt. 0x0: Disables the half frame interrupt 0x1: Enables the half frame interrupt	RW	-
1	DROP_IE	Synchronization event drop interrupt enable (request collision) 0x0: Disables the event drop interrupt 0x1: Enables the event drop interrupt	RW	0
0	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0

PRELIMINARY

## Interrupt Controllers

This chapter describes the interrupt controllers (INTCs) in the device.

Topic	Page
<b>17.1 Interrupt Controllers Overview .....</b>	<b>3300</b>
<b>17.2 Interrupt Controllers Environment .....</b>	<b>3302</b>
<b>17.3 Interrupt Controllers Integration .....</b>	<b>3303</b>
<b>17.4 Interrupt Controllers Functional Description .....</b>	<b>3309</b>
<b>17.5 Interrupt Controllers Register Manual .....</b>	<b>3310</b>

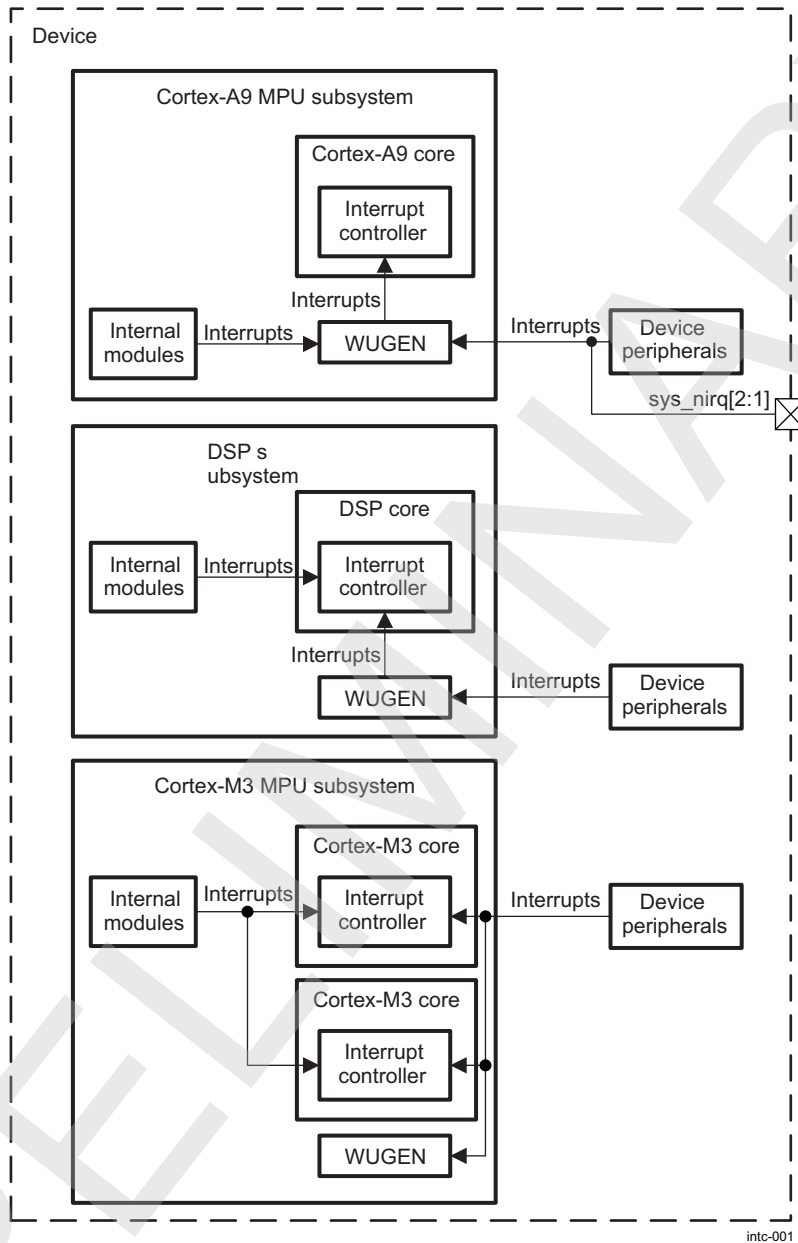

## 17.1 Interrupt Controllers Overview

The device provides three interrupt controller (INTC) modules, which handle interrupts at the device level:

- Cortex™-A9 MPU subsystem (MPUSS) interrupt controller (Cortex-A9 MPU INTC): This INTC module is a single functional unit that is integrated in the Cortex-A9 multiprocessor core alongside Cortex-A9 processors. It provides:
  - 128 hardware interrupt inputs
  - Generation of interrupts by software
  - Prioritization of interrupts
  - Masking of any interrupts
  - Distribution of the interrupts to the target Cortex-A9 processor(s)
  - Tracking the status of interrupts
  - Wake-up generator (WUGEN) module on external and local interrupts
- DSP subsystem (DSPSS) interrupt controller: This module is a specific combination of wake-up generator (WUGEN) and the C64x+ DSP INTC. It is used in the device but not described in detail in this chapter. For detailed information about this module, see [Chapter 5, DSP Subsystem](#).
- Cortex-M3 MPUSS interrupt controller (Cortex-M3 MPU INTC): This module is also called Nested Vectored Interrupt Controller (NVIC) and is integrated within each Cortex-M3 so the different interrupt lines are directly connected to each core. The interrupt mapping is the same for the two cores to facilitate parallel processing. The NVIC supports:
  - 64 external interrupts (in addition to 16 Cortex-M3 internal interrupts), which are dynamically prioritized with 16 levels of priority defined for each core
  - Low-latency exception and interrupt handling
  - Prioritization and handling of exceptions
  - Control of the local power management
  - Debug accesses to the processor core
  - Wake-up generator (WUGEN) module on external interrupts, coming from device peripherals

Figure 17-1 shows the internal interrupt scheme of the device.

Figure 17-1. Interrupt Controllers Overview

**NOTE:** For more information about the WUGEN module in the Cortex-A9 MPUSS (including integration, functional and register description), see [Chapter 4, Cortex-A9 MPU Subsystem](#). For more information about the WUGEN module in the Cortex-M3 MPUSS (including integration, functional and register description), see [Chapter 7, Cortex-M3 MPU Subsystem](#).

## 17.2 Interrupt Controllers Environment

This section describes the INTC application fields from the environment point of view (external connections).

Figure 17-2 shows the relationship between the module and external interrupts.

**Figure 17-2. Interrupts From External Devices**

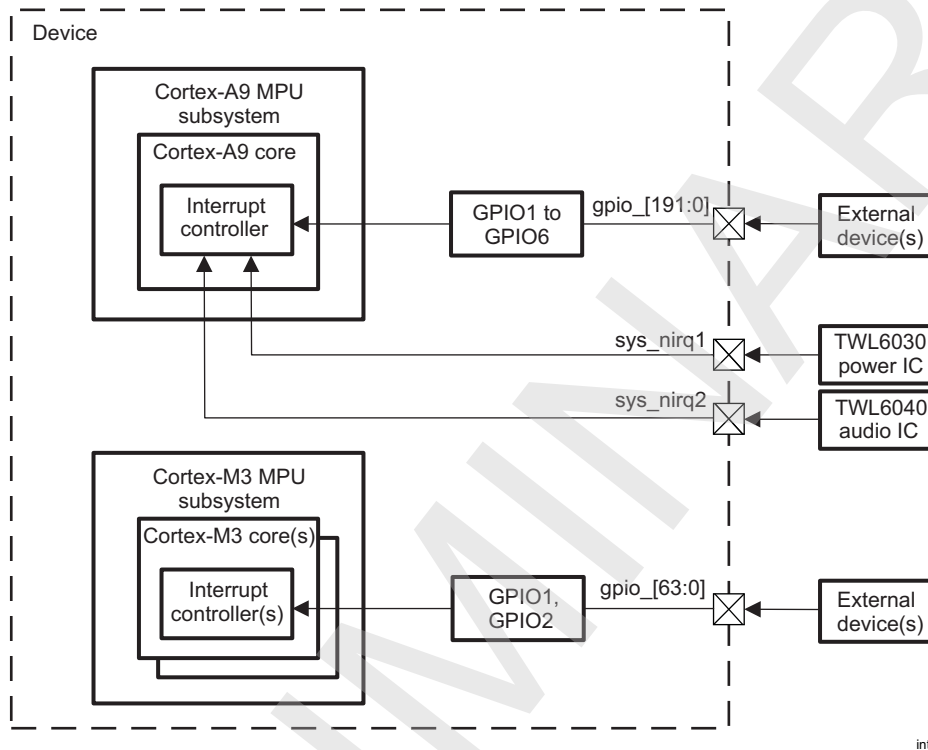

Table 17-1 describes the I/O signals that can be used by external devices to generate interrupts to the Cortex-A9 MPU INTC or Cortex-M3 MPU INTC.

**Table 17-1. Interrupt Controllers I/O Signals**

Signal Name	I/O <sup>(1)</sup>	Reset Value	Description	Cortex-A9 MPU INTC	Cortex-M3 MPU INTC
sys_nirq1	I	1	TWL6030 power IC can use this pin to generate a system wake-up event to Cortex-A9 MPU INTC.	x	-
sys_nirq2	I	1	TWL6040 audio IC can use this pin to generate a system wake-up event to Cortex-A9 MPU INTC.	x	-
gpio_[31:0]	I/O	-	External devices can use GPIO modules to generate interrupts to the Cortex-A9 MPU or Cortex-M3 MPU. There are six dedicated interrupt lines (for GPIO1 to GPIO6) to the Cortex-A9 MPU INTC and two dedicated interrupt lines (for GPIO1 and GPIO2) to the Cortex-M3 MPU INTC. Each GPIO module can generate a single interrupt whenever there is at least one event in any one of the configured 32 GPIO inputs. For more information about GPIO interrupt generation, see <a href="#">Chapter 25, General-Purpose Interface</a> .	x	x
gpio_[63:32]	I/O	-		x	x
gpio_[95:64]	I/O	-		x	-
gpio_[127:96]	I/O	-		x	-
gpio_[159:128]	I/O	-		x	-
gpio_[191:160]	I/O	-		x	-

<sup>(1)</sup> I = Input, O = Output

## 17.3 Interrupt Controllers Integration

The Cortex-A9 MPU INTC is integrated inside the Cortex-A9 MPU core. For more information about Cortex-A9 MPU INTC integration, see [Chapter 4, Cortex-A9 MPU Subsystem Integration](#).

The Cortex-M3 MPU INTC is integrated inside each Cortex-M3 MPU core. For more information about Cortex-M3 MPU INTC integration, see [Chapter 7, Dual Cortex-M3 MPU Subsystem Integration](#).

### 17.3.1 Interrupts Mapping

**NOTE:** All device peripherals interrupts (external to the Cortex-A9 MPU, DSP, and Cortex-M3 MPU subsystems) are active-high, level sensitive.

#### CAUTION

A single interrupt source can be physically mapped to multiple INTCs (Cortex-A9 MPU, DSP, and Cortex-M3 MPU subsystems). With multiple-mapped interrupts, it is strongly recommended to unmask each interrupt source in only one INTC at a time.

### 17.3.2 Interrupt Requests to Cortex-A9 MPU INTC

[Table 17-2](#) shows the Cortex-A9 MPU INTC interrupt mapping.

**Table 17-2. Cortex-A9 MPU INTC Interrupt Mapping**

**NOTE:** MM\_IRQ\_0 triggers exception #16 inside the Cortex-M3 core(s).

---

**NOTE:** All Cortex-M3 MPUSS internal interrupts are edge interrupts, except the one generated from the MMU (XLATE\_MMU\_FAULT), which is level interrupt.

---

## 17.4 Interrupt Controllers Functional Description

### 17.4.1 Cortex-A9 MPU INTC Functional Description

Cortex-A9 MPU INTC is configured to have the following interrupt sources:

- 16 Interprocessor interrupts (IPI): ID[15:0]
- 2 private Timer/Watchdog interrupts: ID[30:29]
- 2 legacy nFIQ & nIRQ: one per CPU, bypasses the interrupt distributor logic and directly drives interrupt requests into CPU if used in legacy mode (else treated like other interrupts lines with ID28 and ID31 respectively)
- 128 hardware interrupts: ID[159:32] (rising-edge or high-level sensitive). The interrupt mapping of these interrupts is presented in [Table 17-2, Interrupt Requests to Cortex-A9 MPU INTC](#).

#### CAUTION

Although the hardware interrupts can be configured to be rising-edge or high-level sensitive in the INTC, the device supports only active-high, level-sensitive configuration.

For more information about the functionality of the Cortex-A9 MPU INTC, see *ARM Cortex-A9 MP Core Technical Reference Manual*.

### 17.4.2 Cortex-M3 MPU INTC Functional Description

The Cortex-M3 MPU INTC has the following configuration in the device:

- 64 hardware interrupts/16 levels of priority for each Cortex-M3 core. The interrupt mapping of these interrupts is presented in [Table 17-3, Interrupt Requests to Cortex-M3 MPU INTC](#).
- The calibration register, which is used to reload the SYSTICK timer to generate a fixed interval, is not supported in the Cortex-M3 core within the Cortex-M3 MPUSS. The TENMS field is not available due to the different frequencies during voltage scaling.
- The SYSRESETREQ reset feature is not supported at the Cortex-M3 processor level. Writing to this bit has no effect.

For more information about the functionality of the Cortex-M3 MPU INTC, see *ARM Cortex-M3 Technical Reference Manual*.

## 17.5 Interrupt Controllers Register Manual

### 17.5.1 Interrupt Controllers Instance Summary

For information about the Cortex-A9 MPU INTC and Cortex-M3 MPU INTC instances, see [Chapter 4, Cortex-A9 MPU Subsystem](#) and [Chapter 7, Dual Cortex-M3 Subsystem](#).

### 17.5.2 Cortex-A9 MPU INTC Registers

For information about the Cortex-A9 MPU INTC registers and their description, see *ARM Cortex-A9 MP Core Technical Reference Manual*.

### 17.5.3 Cortex-M3 MPU INTC Registers

For information about the Cortex-M3 MPU INTC registers and their description, see *ARM Cortex-M3 Technical Reference Manual*.

<b>18.6 Control Module Register Manual .....</b>	<b>3432</b>

## 18.1 Control Module Overview

The control module allows software control of the various static modes supported by the device. It is composed of two control submodules: General Control Module and Device (Padconfiguration) Control Module.

The General Control Module has the following features:

- General status and control
- Hardware observability input/output (I/O) multiplexing
- System boot decoding logic
- Standard eFuse logic

The Device Control Module provides the following features:

- Pad functional I/O multiplexing
- Pad pullup / pulldown configuration
- Pad groups associated signal integrity controls
- Complex I/O configuration
- Analog function control
- Device specific eFuse registers

Both control submodules are additionally split into two instances: the control core instance within the CORE power domain, and the control wake-up instance within the WKUP power domain. For more details on the four different control module instances, see [Section 18.3, Control Module Integration](#).

[Figure 18-1](#) shows the overview of the control module.

Figure 18-1. Control Module Overview

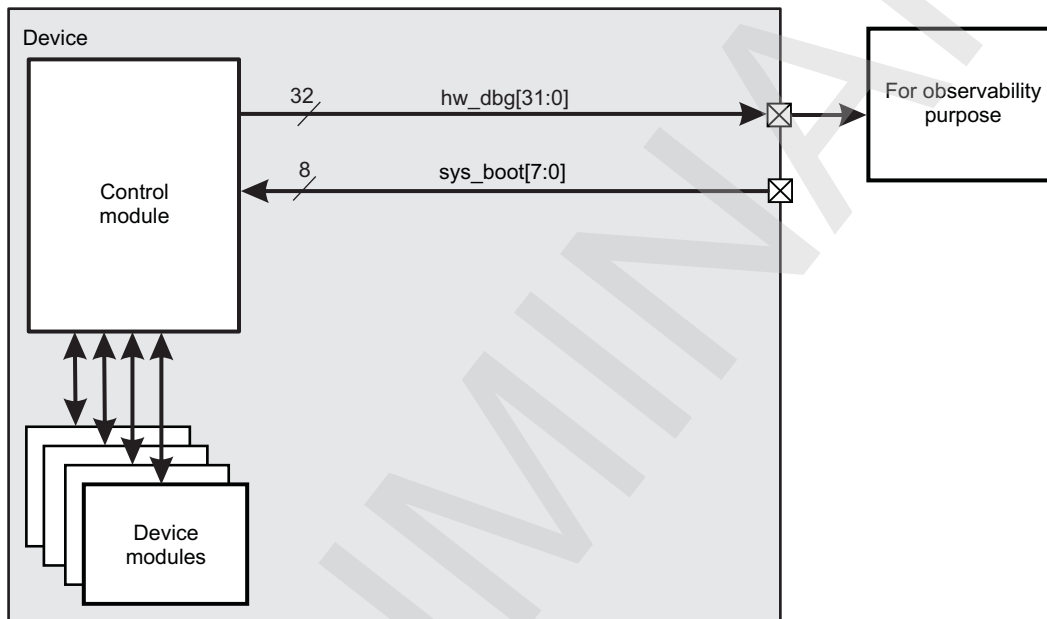

sysctrl-001

## 18.2 Control Module Environment

The control module integrates the system boot decoding logic accessible from eight external input pins (`sys_boot[7:0]`).

The control module controls the multiplexing of device internal module signals routed to the external pins (`hw_dbg[31:0]`) for hardware debug purposes. See [Section 18.4.11, Hardware Observability](#) and [Section 18.4.8, PAD Functional Multiplexing and Configuration](#) for more details. Using the correct pad configuration, the control module maps these pins at the device boundary to observe the internal signals from the power, reset and clock management (PRCM) modules signals, direct memory access (DMA) requests, and interrupts. [Figure 18-2](#) shows an overview of the control module environment.

**Figure 18-2. Control Module Environment**

sysctrl-002

### 18.2.1 Control Module Signals

[Table 18-1](#) lists the control module booting inputs and hardware observability outputs configured to observe device module debug signals. It describes the module signals and specifies their links to functions.

**Table 18-1. Control Module I/O Description**

Signal	I/O <sup>(1)</sup>	Description	Reset Value <sup>(2)</sup>
<code>hw_dbg[31:0]</code>	O	Internal hardware observability signals 0 to 31	HiZ
<code>sys_boot[7:0]</code>	I	Boot mode configuration signals 0 to 7	HiZ

<sup>(1)</sup> I = Input; O = Output

<sup>(2)</sup> HiZ = High impedance

### 18.3 Control Module Integration

The control module of the device is on the L4-Core interconnect. It consists of four module instances:

- General Core Control module (SYSCTRL\_GENERAL\_CORE)
- General Wakeup Control module (SYSCTRL\_GENERAL\_WKUP)
- Device Core Control module (SYSCTRL\_PADCONF\_CORE)
- Device Wakeup Control module (SYSCTRL\_PADCONF\_WKUP)

For more information about the different control module instances, see [Table 18-3](#).

Each of these four module instances has an associated register set and shares one functional clock and one reset signal with the *PRCM* module. These signals are described in [Table 18-2](#).

**Table 18-2. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SYSCTRL_GENERAL_WKUP	GEN_L4WKUP_CLK	WKUP_L4_ICLK2	PRCM	L4_WKUP interface/functional clock propagated to the General Wakeup Control module
SYSCTRL_GENERAL_CORE	GEN_L4CFG_CLK	CFG_L4_ICLK	PRCM	L4_CFG interface/functional clock propagated to the General Core Control module
SYSCTRL_PADCONF_WKUP	PADCONF_L4WKUP_CLK	WKUP_L4_ICLK2	PRCM	L4_WKUP interface/functional clock propagated to the Device Wakeup Control module
SYSCTRL_PADCONF_CORE	PADCONF_L4CFG_CLK	CFG_L4_ICLK	PRCM	L4_CFG interface/functional clock propagated to the Device Core Control module
Resets				
SYSCTRL_GENERAL_WKUP	GEN_WKUP_NONRET_RST	WKUP_PWRON_RST	PRCM	Internal power-on reset affecting General Wakeup Control module
SYSCTRL_GENERAL_CORE	GEN_CORE_RET_RST	CORE_PWRON_RET_RST	PRCM	Internal power-on reset affecting the General Core Control module
SYSCTRL_PADCONF_WKUP	PADCONF_WKUP_NONRET_RST	WKUP_PWRON_RST	PRCM	Internal power-on reset affecting the Device Wakeup Control module
SYSCTRL_PADCONF_CORE	PADCONF_CORE_RET_RST	CORE_PWRON_RET_RST	PRCM	Internal power-on reset affecting the Device Core Control module

The control module is reset by the internal power-on reset which is active low. The PRCM provides a retention power-on reset signal (CORE\_PWRON\_RET\_RST) duplicated to each of the two core control module instances, and a nonretention power-on reset signal (WKUP\_PWRON\_RST) duplicated to each of the two wake-up control module instances in the control module. For further details see [Section 3.5.4](#), *Reset Domains*, in [Chapter 3, Power, Reset, and Clock Management](#). The control module does not respond to a warm reset or to an L4-Core reset.

The main sequential logic within the system control module is accessible in a register file through the L4-Core. The PRCM module provides the CFG\_L4\_ICLK functional clock signal (L4\_CFG -clock domain) separately to each of the two core control submodules. See [Section 3.6.3.2.4, CM2 Clock Generator](#) in [Chapter 3, Power, Reset, and Clock Management](#) for further details on this signal.

The PRCM module also supplies the WKUP\_L4\_ICLK2 functional clock signal (L4\_WKUP -clock domain) to each of the two wake-up control module instances. See [Section 3.6.3.1, PRM Clock Source](#) in [Chapter 3, Power, Reset, and Clock Management](#) for further details on this signal.

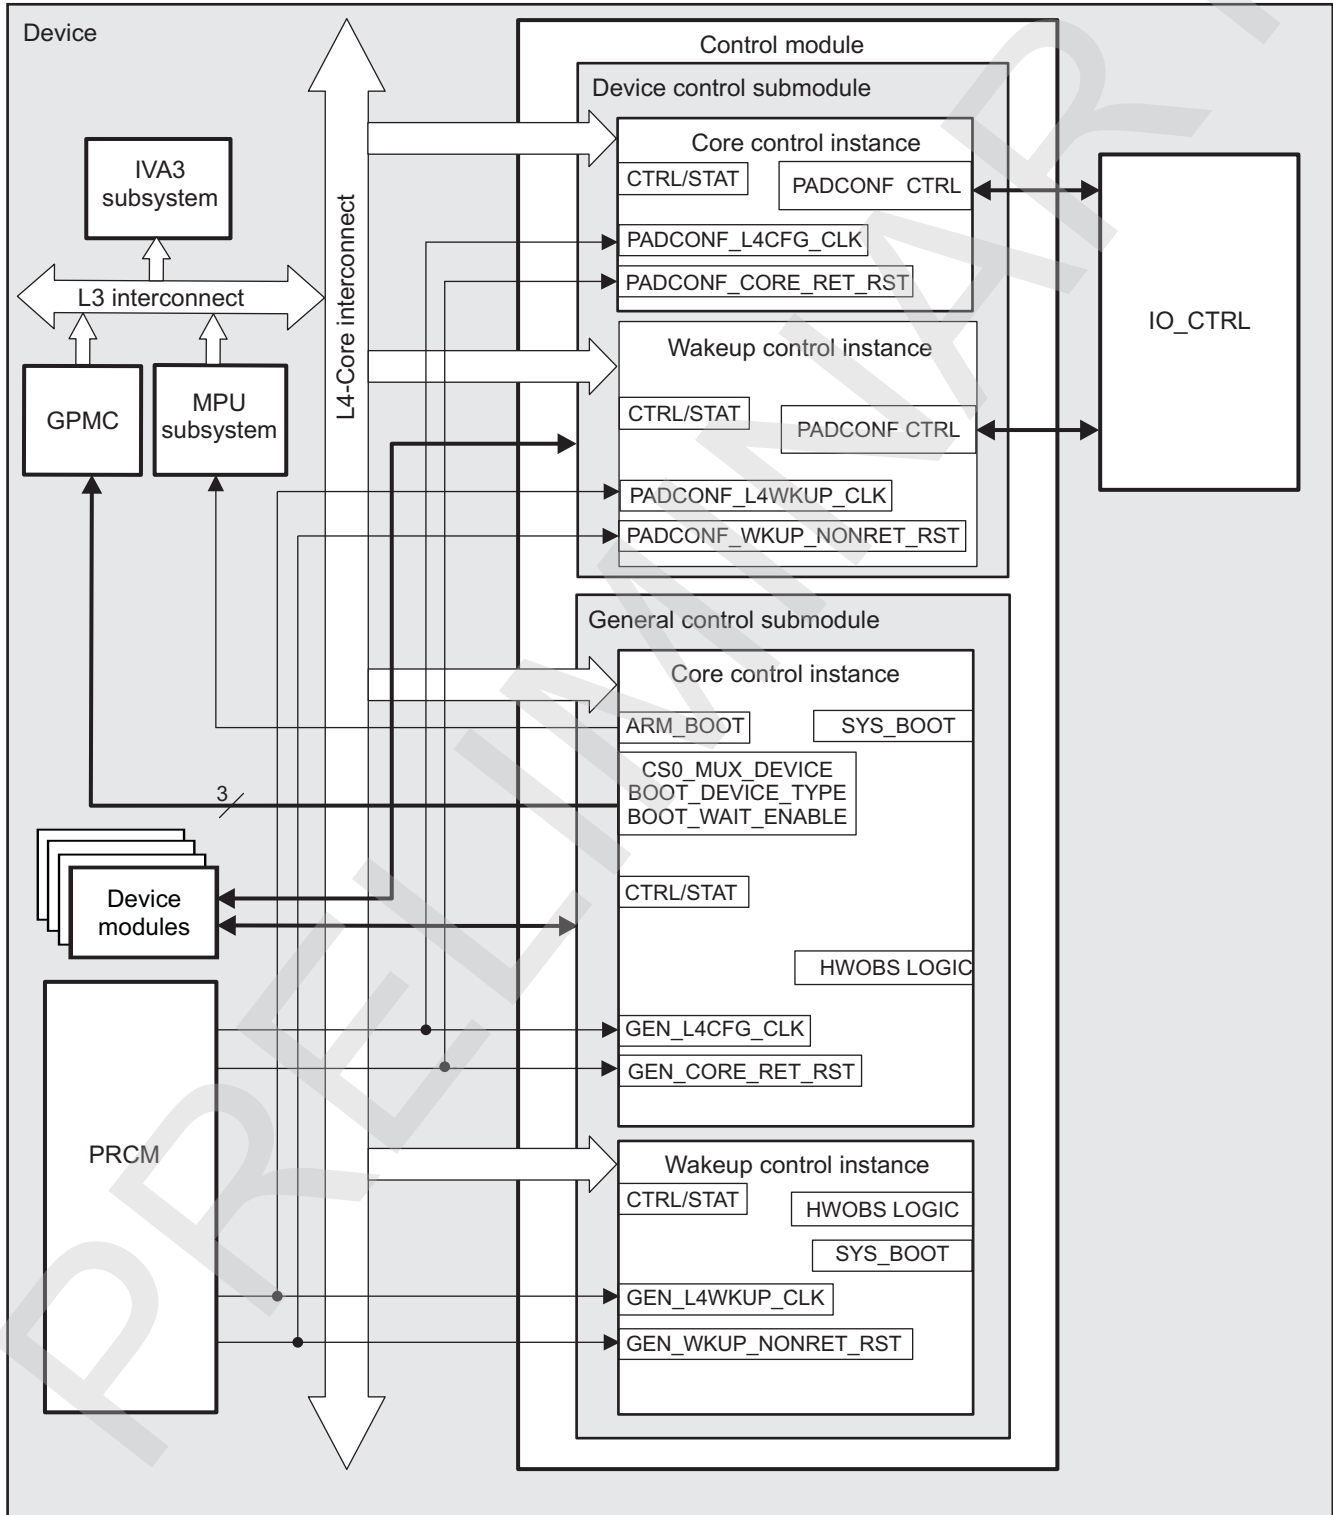

The signal integration of the control module features:

- No IDLE hardware handshake
- No STANDBY hardware handshake
- No SAVE and RESTORE hardware handshake
- No Wake-up request generation
- No DMA request generation
- No interrupt request (IRQ) generation

- Two functional clocks, one within the CFG- and the other within WKUP- clock domains
- One retention and one nonretention internal power-on based resets

Figure 18-3 summarizes the integration of the module in the device.

**Figure 18-3. Control Module Integration**

sysctrl-003

**Table 18-3. Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
SYSCTRL_GENERAL_WKUP	PD_WKUP	L4_WKUP
SYSCTRL_GENERAL_CORE	PD_CORE	L4_CFG
SYSCTRL_PADCONF_WKUP	PD_WKUP	L4_WKUP
SYSCTRL_PADCONF_CORE	PD_CORE	L4_CFG

The software sets the configuration registers to the desired values depending on the configuration of the requested device. Static device configuration registers can be set by the software at any time and are effective immediately.

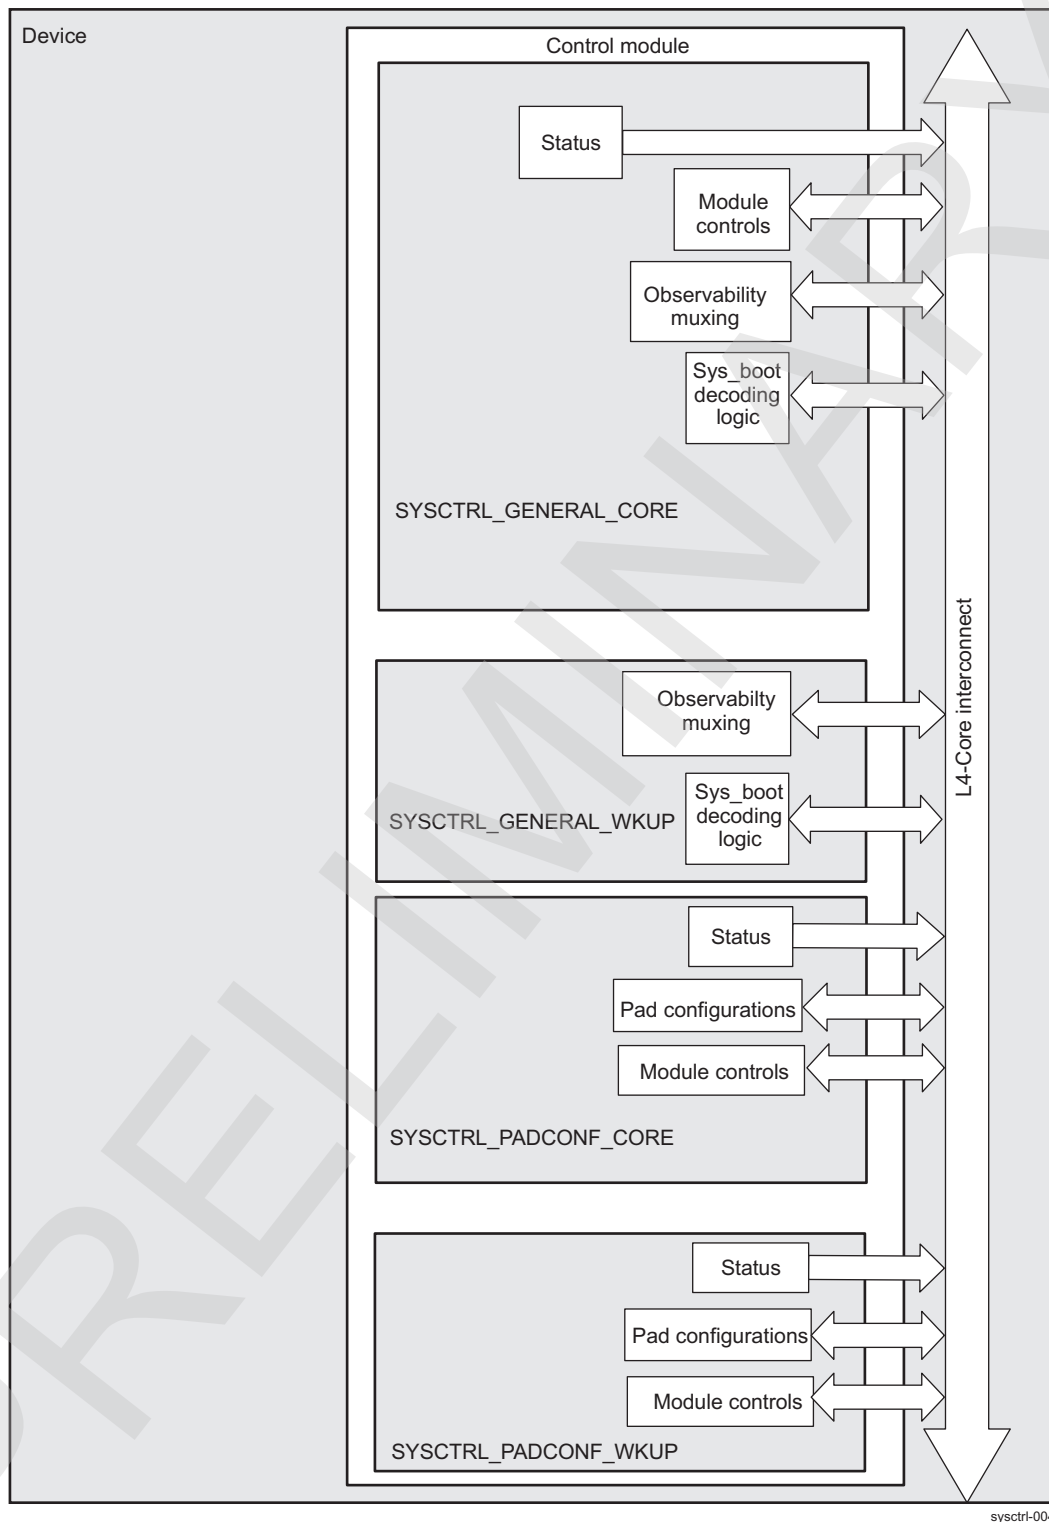

## 18.4 Control Module Functional Description

### 18.4.1 Control Module Block Diagram

The control module controls the settings of various device modules through register configuration and internal signals. It also controls the pad configuration, pin functional multiplexing and the routing of internal signals (such as PRCM signals or DMA requests) to output pins configured for hardware observability.

Figure 18-4 is the control module block diagram.

Figure 18-4. Control Module Block Diagram

Each of the control submodules primarily implements a bank of registers accessible (read/write) by the software along with some read only registers carrying status information.

Read/write registers available in the General Control Module can be divided into the following classes:

- Hardware observability registers (32-bit- read/write register)

- Status and configuration registers
- Boot registers
- eFuse ROM registers
- Miscellaneous functional registers

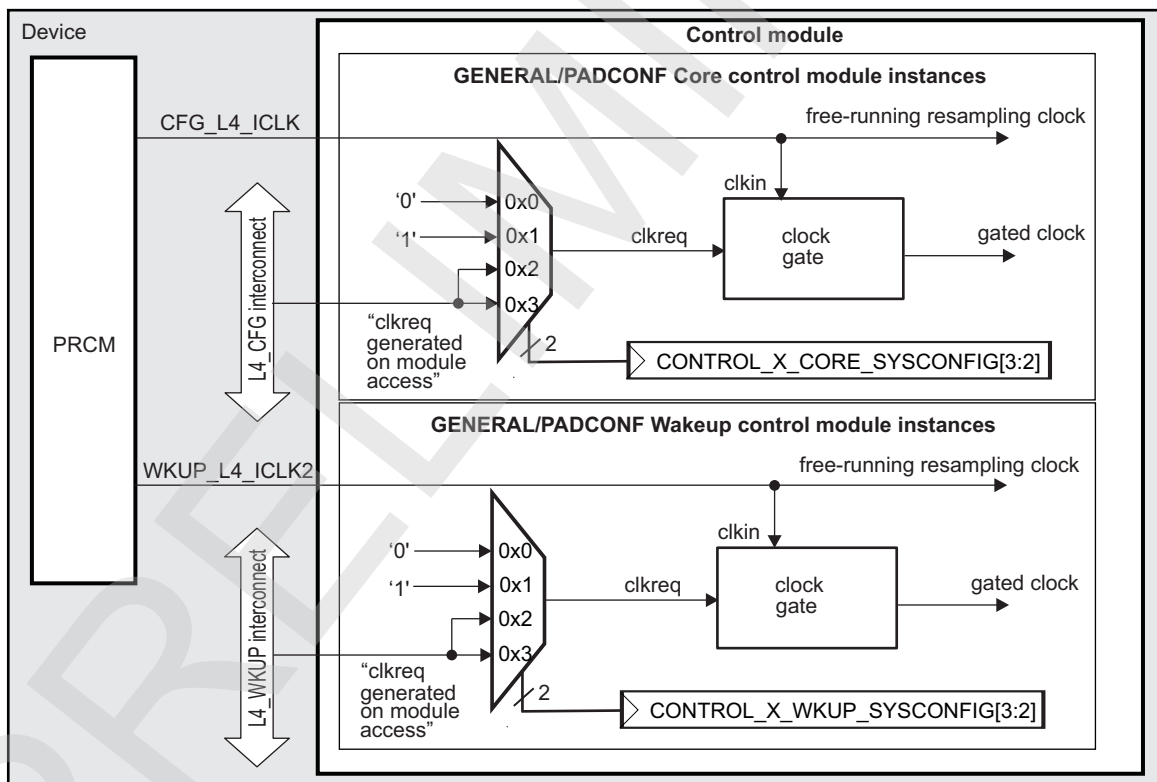

Read/write registers available in the Device(Padconfiguration) Control Module can be divided into the following classes:

- Pad configuration registers (32-bit- registers, one register for two pads)
- Pad groups (not individual per pad) associated registers for signal integrity parameters control (32-bit read/write registers )
- I/O cells associated specific control registers
- Device specific status and configuration registers
- Miscellaneous functional registers

### 18.4.2 Control Module Clock Configuration

Figure 18-5 shows the control module internal clock distribution schema. Each of the CFG\_L4\_ICLK and WKUP\_L4\_ICLK2 source clocks is internally distributed into two clock paths: the first one directly mirrors the source clock and is an always-running clock. It is used to synchronize and resample some of the module inputs. The other clock path can be internally gated within the module.

**Figure 18-5. Control Module Internal Clock Paths**

sysctrl-005

The clock gating strategy is selected through the bit field CONTROL\_SYSCONFIG[3:2] IP\_SYSCONFIG\_IDLEMODE available in each of the four Control Module instances. The different possibilities for clock management, are described in Table 18-4. There are no PRCM software controls for the Control Module clocks. There are however clock activity status bits located in PRCM. See Section 3.6.14.2, *Clock Domain Modes* and Section 3.6.4, *CD\_WKUP Clock Domain* in Chapter 3, *Power, Reset, and Clock Management*.

**Table 18-4. Internal Clock Gating Options**

Feature	CONTROL_SYSCONFIG[3:2] IP_SYSCONFIG_IDLEMODE value	Description
Local clock control	0b00	Clock is manually gated
Local clock control	0b01	Clock is manually enabled
Local clock autogating	0b10,0b11	Clock is automatically gated when there is no access to the Control Module through L4-interconnect

### 18.4.3 Control Module Software Reset

The control module is not sensitive to software reset.

### 18.4.4 Control Module Power Management

#### 18.4.4.1 Retention

The General- and Device Core Control module instances are fully built with retention flip-flop (RFF) and are powered in the core domain, so they can be in either active or retention mode. The core instances lose their content when the CORE power domain is in OFF mode. In contrast to the core control instances, the control wake-up instances are always powered and active. [Section 3.9, Device Low-Power States](#) in [Chapter 3, Power, Reset, and Clock Management](#) provides more information about the device low power states.

#### 18.4.4.2 Power Management Protocols

The control module, which is slave on the L4-interconnect, supports neither STANDBY nor IDLE mode protocols.

#### 18.4.4.3 Save and Restore (SAR) Mechanism

The control core module instances lose their contents when the CORE power domain is in OFF mode. To prevent this, before going to OFF mode, the core register context is copied by software into a dedicated SAR\_RAM sitting in the WKUP voltage domain. The save-and-restore (SAR) mechanism, controlled by the PRCM module, allows them to restore registers to a predefined value (not reset value, but value defined by the boot code). Thus core domain registers will have a correct configuration/state immediately after core power is on again without requesting a software operation to reconfigure them.

Because the SAR mechanism is managed by software-accessible registers, no hardware-specific requirements exist. For more details on SAR, see [Section 3.9.3, Device Off State Management](#) in [Chapter 3, Power, Reset, and Clock Management](#)

### 18.4.5 Hardware Requests

The control module does not generate interrupt, dma, or wake-up requests.

### 18.4.6 Control Module Initialization

The control module responds only to the internal power-on reset and device type. At power-on, reset values for the registers define the *safe state* for the chip. In the initialization mode, only modules to be used at boot time are associated to the pads. Other module inputs are internally tied and outputs pads are turned off. After power-on reset, the software is in charge of setting the pad functional multiplexing and configuration registers to the desired values according to the requested chip configuration. See [Chapter 27, Initialization](#), for further information.

General-purpose (GP) devices include features that are inaccessible or unavailable. These inaccessible registers define the default or fixed device configuration or behavior.

The [CONTROL\\_STATUS\[7:0\]](#) SYS\_BOOT reflects the state of the sys\_boot pins captured at power-on reset.

## 18.4.7 Control Module Instances

### 18.4.7.1 General Core Control Module Instance

The SYSCTRL\_GENERAL\_CORE instance contains most of the control logic providing hardware observability features for different DPLL clockout and DPLL -specific signals, DMA requests , IRQs, and other internal hardware signals. The General Core Control provides the system boot decoding logic and has control over the standard E-fuse settings. The system configuration registers, specific function controls, some peripheral control and status registers are also mapped there.

The register sets available within the SYSCTRL\_GENERAL\_CORE are:

- Observability control registers - [CONTROL\\_HWOBS\\_CONTROL](#), [CONTROL\\_DEBOBS\\_FINAL\\_MUX\\_SEL](#), [CONTROL\\_CONF\\_SDMA\\_REQ\\_SELx](#), [CONTROL\\_CONF\\_CLK\\_SELx](#) (x=0 to 2), [CONTROL\\_CONF\\_DPLL\\_X\\_SEL](#) ( where X is FREQLOCK, TINITZ, PHASELOCK, TENABLE, TENABLEDIV, BYPASSACK, IDLE)
- Part of the debug view channel selection registers - [CONTROL\\_CORE\\_CONF\\_DEBUG\\_SEL\\_TST\\_X](#)
- MMU address translation related registers - [CONTROL\\_CORTEX\\_M3\\_MMUADDRTRANSLTR](#), [CONTROL\\_CORTEX\\_M3\\_MMUADDRLOGICTR](#)
- Standard fuse registers - [CONTROL\\_STD\\_FUSE\\_X](#)
- Clock gating configuration register - [CONTROL\\_GEN\\_CORE\\_SYSCONFIG](#)
- Control status register - [CONTROL\\_STATUS](#)
- Peripheral controls - [CONTROL\\_TEMP\\_SENSOR](#), [CONTROL\\_DSS\\_CONTROL](#), [CONTROL\\_USBOTGHS\\_CONTROL](#), [CONTROL\\_LDOSRAM\\_MPU\\_VOLTAGE\\_CTRL](#), etc.

### 18.4.7.2 General Wakeup Control Module Instance

Associated registers are:

- Clock gating configuration register - [CONTROL\\_GEN\\_WKUP\\_SYSCONFIG](#)
- Register with spare bits - [CONTROL\\_OCPREG\\_SPARE](#)
- Part of the debug view channel selection registers - [CONTROL\\_WKUP\\_CONF\\_DEBUG\\_SEL\\_TST\\_X](#)

### 18.4.7.3 Device Core Control Module Instance

The SYSCTRL\_PADCONF\_CORE instance provides the device specific PAD control features like pullup and pulldown I/O configuration and pad functional multiplexing. Wake-up control/status features are also subject of the Device Core Control.

The registers associated to this module are:

- Clock gating configuration register - [CONTROL\\_PADCONF\\_CORE\\_SYSCONFIG](#)
- Different peripheral pad mode configuration and wake-up status/configuration - [CONTROL\\_CORE\\_PAD0\\_X\\_PAD1\\_Y](#) , [CONTROL\\_PADCONF\\_WAKEUPEVENTx](#) , [CONTROL\\_PADCONF\\_GLOBAL](#), [CONTROL\\_SMARTxIO](#), [CONTROL\\_C2CIO\\_PADCONF\\_0](#), etc.
- Peripheral pad voltage-level control registers - [CONTROL\\_PADCONF\\_MODE](#)
- Miscellaneous controls for different device interface modules - [CONTROL\\_X](#) registers (including [CONTROL\\_EFUSE](#) registers)

### 18.4.7.4 Device Wakeup Control Module Instance

Configuration registers for all pads linked to the wake-up voltage domain are in the WKUP device control module. The registers instantiated here are:

- Clock gating configuration register - [CONTROL\\_PADCONF\\_WKUP\\_SYSCONFIG](#)
- [CONTROL\\_WKUP\\_PAD0\\_X\\_PAD1\\_Y](#) registers for configuring FREF clock oscillator pads, reset signals and power mode pad configurations

---

**NOTE:** SYSCTRL\_PADCONF\_X alias notifies a Device Control module Instance.

---

Table 18-112 shows the memory size and base addresses assigned to the different control module instances

### 18.4.8 PAD Functional Multiplexing and Configuration

After power-on reset, the software has in charge to set the pad functional multiplexing and configuration registers to the desired values according to the requested chip configuration. The configuration is controlled by pads or by group of pads. Each configurable pin has its own configuration register for pullup/down control and for the assignment to a given module.

Two sets of 32-bit registers provide the PAD functional multiplexing and configuration feature of the control module. The first set of registers CONTROL\_CORE\_PAD0\_X\_PAD1\_Y provides the configuration of pads in the CORE power domain. The second set of registers CONTROL\_WKUP\_PAD0\_X\_PAD1\_Y configures pads in the WKUP power domain.

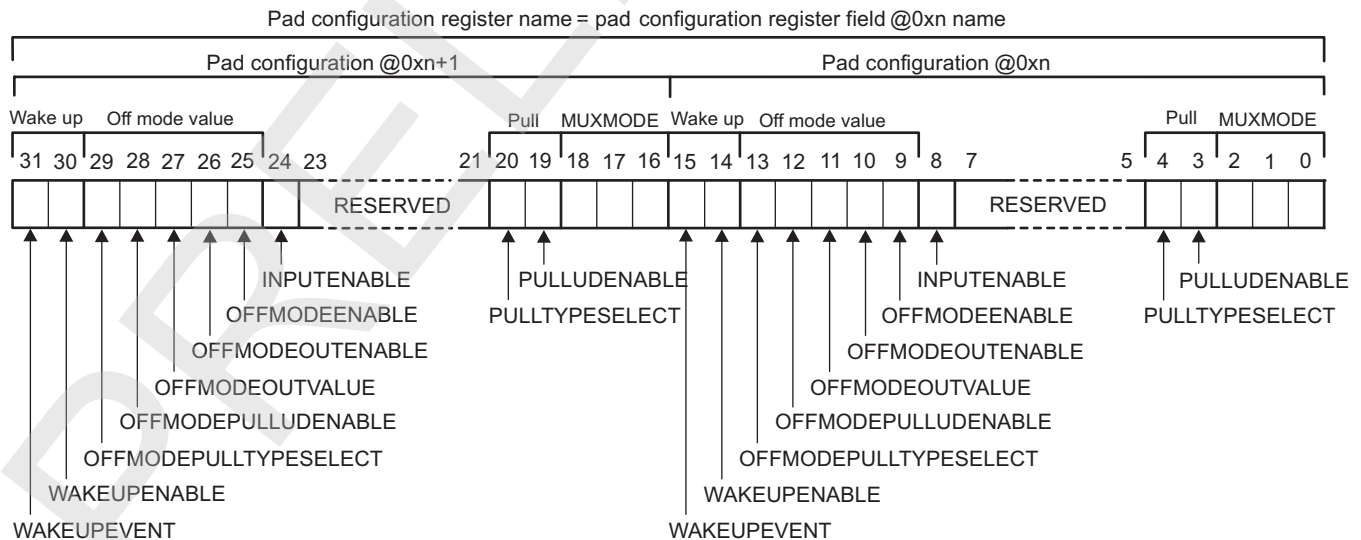

The pads configuration as defined in this module is used in the IO\_CTRL logic along with the gating and protection features. The Gating feature is implemented for the output pads. The Protection feature is implemented for input lines. These features implement additional control and multiplexing capabilities hard-wired in the IO\_CTRL logic and driven by internal device state and/or logic.

The gating feature allows forcing an output pad to a fixed value (Z, pullup, pulldown, 1, 0) or to a given internal signal. Each gating command is defined with a logic equation and the output state/value to be set on the pad when the logic equation is "True".

The protection feature provides control on each input line of the module when no pad is assigned to this input (protected value).When POR is released, the value on the pad is driven by the default configuration of control module. Most of time, this configuration is aligned with default value selected on the I/O cell. The protected value can be logical level (0 or 1) or a signal from a pad; it is selected when none of the pad\_x.MuxMod is selecting a chip input.

Each 32-bit PADCONF register controls two pads: the first pad is controlled by the 16 least significant bits (LSBs), and the second pad is controlled by the 16 most significant bits (MSBs), hence one pad configuration register provides control for two different pins. After power-on reset, the software sets the pad functional multiplexing and configuration registers to the requested device pad configurations. Data written in these registers directly command the multiplexing of the pad configuration logic. Figure 18-6 describes the associated to each pin 16-bit-wide pad configuration register field.

Figure 18-6. Pad Configuration Register Functionality

**NOTE:** These registers can be accessed using 8-, 16-, and 32-bit operations.

The functional bits of a pad configuration register field are divided into the following five fields:

- MUXMODE (3 bits) defines the multiplexing mode applied to the pin. A mode corresponds to the selection of the functionality mapped on the pin with seven (0 to 6) possible functional modes for each pin.
- PULL (2 bits) for combinational pullup/pulldown configuration:
  - PULLTYPESELECT: Pullup/pulldown type selection for the pin
  - PULLUDENABLE: Enables Pullup/pulldown feature for the pin
- INPUTENABLE (1 bit) drives an input enable signal to the I/O CTRL
  - INPUTENABLE = 0: Input disable. Pin is configured in output only mode
  - INPUTENABLE = 1: Input enable. Pin is configured in bidirectional mode
- Off mode values (1 bit) override the pin state when the OFFMODEENABLE bit in CONTROL\_CORE\_PAD0\_X\_PAD1\_Y is set and off mode is active. This feature allows having separate configurations (5 bits) for the pins when in off mode:
  - OFFMODEENABLE: Off mode pin state override control. Set to 1 to enable the feature and to 0 to disable it
  - OFFMODEOUTENABLE: Off mode output enable value. Set to 0 to enable the feature and to 1 to disable it
  - OFFMODEOUTVALUE: Off mode output value.
  - OFFMODEPULLUDENABLE: Off mode pullup/pulldown feature enable
  - OFFMODEPULLTYPESELECT: Off mode pullup/pulldown type selection
- Wake-up bits (2 bits):
  - WAKEUPENABLE: Enable wake-up detection on input. It is also the off mode input enable value.
  - WAKEUPEVENT: Wake-up event status for the pin.

**CAUTION**

Software must configure the OFF mode pads. It must ensure that the input/output capability is enabled for each pin.

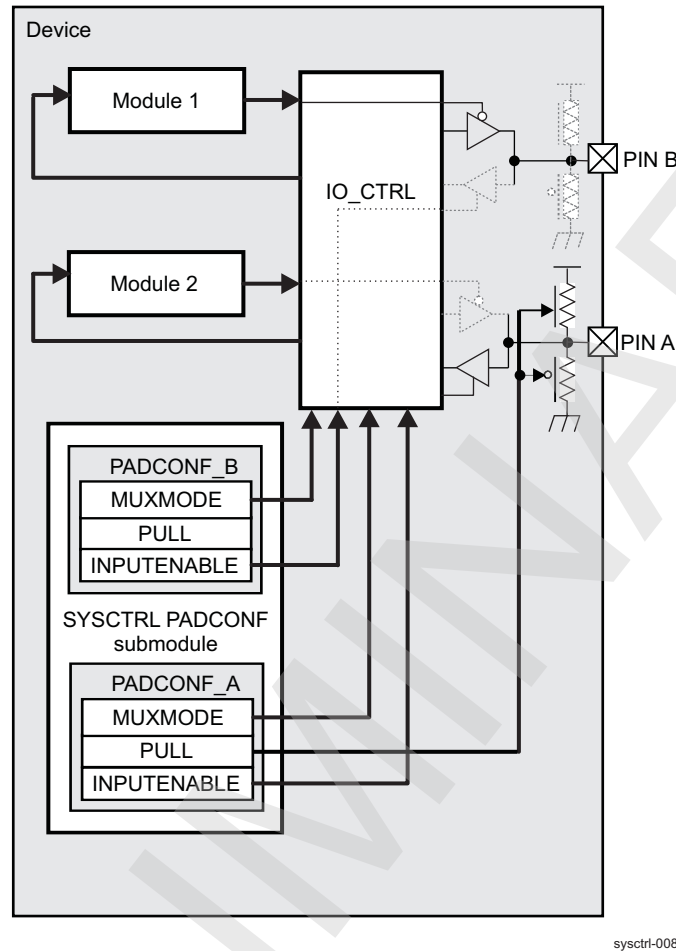

**CAUTION**

The OFFOUTENABLE and OFFOUTVALUE bits are functional only if the pad configuration supports output mode on at least one MUXMODE. For a pad that supports only the input feature, the OFFOUTENABLE and OFFOUTVALUE bits cannot be configured (they are don't care and read always returns 0).

**NOTE:** Because off-mode has impact only on pads in CORE domain, OFFMODE-related bits are not present in WKUP power domain padconfiguration registers.

Figure 18-7 shows the pad configuration functionality when off mode is inactive. For more information about off mode, see [Section 18.4.8.4, Off Mode](#).

Figure 18-7. Pad Configuration Diagram

The I/O pads are software-controlled by:

- Writing to the CONTROL\_(CORE/WKUP)\_PAD0\_X\_PAD1\_Y registers in the Device Control Module for input/output and pullup / pulldown configuration.
  - Writing to the GPIOi.GPIO\_OE registers in the GPIO module for input/output configuration.
- For more information about how to configure the I/O pads, see [Section 18.5.1.2.5, Pad Configuration Programming Points](#).

For more information about the GPIO module, see [Section 25.4.8, General-Purpose Interface Data Input/Output Capabilities](#).

**NOTE:** For a correct configuration of each pin direction (input, output, bidirectional), the CONTROL\_(CORE/WKUP)\_PAD0\_X\_PAD1\_Y and the GPIOi.GPIO\_OE registers must be written.

[Table 18-5](#) lists the bit directions of the CONTROL\_(CORE/WKUP)\_PAD0\_X\_PAD1\_Y registers.

Table 18-5. Bit Meanings for CONTROL\_PADCONF\_x Registers

Pad Configuration Bit	Bit Meaning	
	0	1
PULLUDENABLE	Not activated	Activated
PULLTYPESELECT	Pulldown	Pullup
INPUTENABLE	Input enable signal inactive	Input enable signal active

**Table 18-5. Bit Meanings for CONTROL\_PADCONF\_x Registers (continued)**

Pad Configuration Bit	Bit Meaning	
	0	1
OFFMODEENABLE	Off mode values are invalid.	Off mode values are valid.
OFFMODEOUTENABLE	Output	Input
OFFMODEOUTVALUE	Low	High
OFFMODEPULLUDENABLE	Not activated	Activated
OFFMODEPULLTYPESELECT	Pulldown	Pullup
WAKEUPENABLE	Disable I/O wake-up function.	Enable I/O wake-up function.
WAKEUPEVENT	Wake-up event not detected	Detect wake-up event.

### 18.4.8.1 Mode Selection

Table 18-6 lists the multiplexing modes and settings.

**Table 18-6. Mode Selection**

MUXMODE	Selected Mode
0b000	Primary mode = Mode 0
0b001	Mode 1
0b010	Mode 2
0b011	Mode 3
0b100	Mode 4
0b101	Mode 5
0b110	Mode 6
0b111	Safe mode = Mode 7

The MUXMODE field in the CONTROL\_CORE\_PAD0\_X\_PAD1\_Y and CONTROL\_WKUP\_PAD0\_X\_PAD1\_Y registers defines the multiplexing mode applied to the pad. Modes are referred to by their decimal (from 0 to 7) or binary (from 0b000 to 0b111) representation. Functional modes are defined from 0b000 to 0b110; mode 0b111 is referred to as the safe mode.

For most pads, the reset value for the MUXMODE field in the CONTROL\_CORE\_PAD0\_X\_PAD1\_Y and CONTROL\_WKUP\_PAD0\_X\_PAD1\_Y registers is 0b111. The exceptions are pads to be used at boot time to transfer data from selected peripherals to the external flash memory.

Mode 0 is the primary mode. When mode 0 is set, the function mapped to the pin corresponds to the name of the pin.

Mode 1 to mode 6 are possible modes for alternate functions. On each pin, some modes are used effectively for alternate functions, while other modes are unused and correspond to no functional configuration.

The safe mode avoids any risk of electrical contention by configuring the pin as an input with no functional interface mapped to it. The safe mode is used mainly as the default mode for all pins containing no mandatory interface at the release of power-on reset.

---

**NOTE:** When a pad is set into a mux mode which is not defined by pin multiplexing, this pad is actually set undriven (HiZ) with potential pullup/down.

---

For more information about the configurable mode on each pin, see [Table 18-9](#) and [Table 18-8](#).

---

**NOTE:** Pad names are signal names available in mode 0.

---

### 18.4.8.2 Pull Selection

Whichever pull value is configured, pulls are automatically disabled when a pin is configured as an output (see [Table 18-7](#)).

**Table 18-7. Pull Selection**

PULL		Pin Behavior
PULLTYPESELECT	PULLUDENABLE	
0b0	0b0	Pulldown selected but not activated
0b0	0b1	Pulldown selected and activated if pin is not configured as OUTPUT
0b1	0b0	Pullup selected but not activated
0b1	0b1	Pullup selected and activated if pin is not configured as OUTPUT

For more information on the pull available on each pin, see [Table 18-9](#) and [Table 18-8](#).

### 18.4.8.3 Pad Multiplexing Register Fields

[Table 18-9](#) and [Table 18-8](#) provide for each pad configuration register field the address offset and associated signal name for each multiplexing mode (as set by bit field MUXMODE). Mode 0 is always defined. Modes with no signal name are undefined for the given pad. For more information about default pad configuration settings (power-on reset values) for pads in the CORE power domain, see [Section 18.6.7](#), *SYSCTRL\_PADCONF\_CORE Register Description*; for pads in the WKUP power domain, see [Section 18.6.9](#), *SYSCTRL\_PADCONF\_WKUP Register Description*.

---

**NOTE:**

- [Table 18-9](#) lists the pad configuration registers instantiated in the CORE power domain that drive the pads in the CORE power domain. [Table 18-8](#) lists the pad configuration registers instantiated in the WKUP power domain that drive the pads in the WKUP power domain.
  - In [Table 18-9](#) and [Table 18-8](#), an empty cell indicates that the mode or pull is not available for this pin.

#### 18.4.8.4 Off Mode PAD Control Overview

When Off mode is selected, which is true when `PRM_DEVICE_OFF_CTRL[0] DEVICE_OFF_ENABLE = 0b1` from PRCM or `CONTROL_PADCONF_GLOBAL[31] FORCE_OFFMODE_ENABLE = 0b1` (force bit to test the value of off mode), the off mode values field `CONTROL_CORE_PAD0_X_PAD1_Y[27,11] OFFMODEOUTVALUE` overrides the pad state when `OFFMODEENABLE` bit `CONTROL_CORE_PAD0_X_PAD1_Y[25,9]` is set.

The `CONTROL_CORE_PAD0_X_PAD1_Y[26,10] OFFMODEOUTENABLE` bit is active low.

Figure 18-8 shows the off mode pad control.

**Figure 18-8. Off Mode Pad control Overview**

If off mode is active and the `OFFMODEENABLE` bit is set to 0 (disable OFF mode override feature), the pad keeps the AND value of the configuration (input/output, PU/PD) it had before going into off mode:

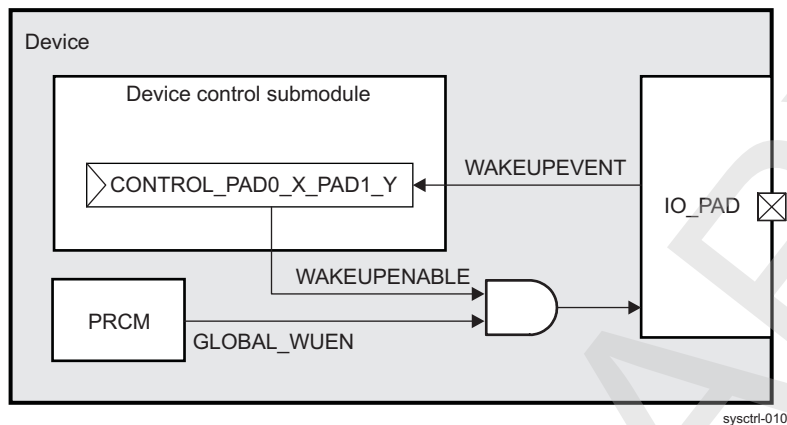

- For an input, the pad is isolated and the pull remains active.
- For an output, the value is latched before going into off mode, to drive the same value in off mode.

##### 18.4.8.4.1 Wake-Up Event Detection

In off mode, wake-up event detection can also be enabled on an input pad. The pad wake-up event is latched in the `WAKEUPEVENT` bit `CONTROL_CORE_PAD0_X_PAD1_Y[31,15]` and `CONTROL_WKUP_PAD0_X_PAD1_Y[31,15]`.

The off mode I/O pads wake-up scheme is enabled by setting the bit `PRM_IO_PMCTRL[16] GLOBAL_WUEN` from PRCM. The wake-up scheme status is transmitted by the `WKUP_ENABLE` signal. The wake-up event detection capability of each I/O pad of the device is individually enabled or disabled by writing `WAKEUPENABLE` bits - `CONTROL_CORE_PAD0_X_PAD1_Y[30,14]` and `CONTROL_WKUP_PAD0_X_PAD1_Y[30,14]`.

Figure 18-9. Wake-Up Event Detection Overview

**NOTE:** When wake-up detection is enabled for a pad, the pad must be configured as input to avoid contention between the device output buffer and an external driver. If this pin is already configured as an input in active mode, hardware automatically retains the same input state; no software action is required.

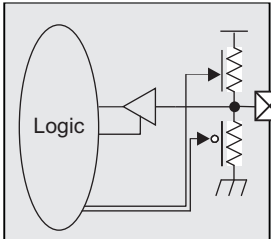

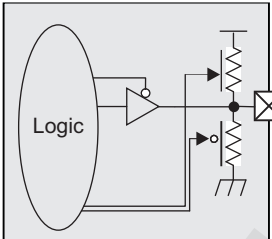

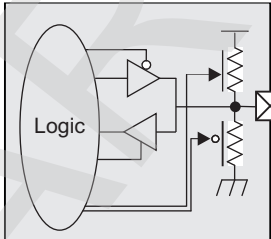

If this pin is configured as an output in active mode, the OFF override function must be enabled to set the pin as an input during off mode: in the CONTROL.CONTROL\_PADCONF register, set OFFMODEENABLE to 0x1 to enable the OFF override function, and set OFFMODEOUTENABLE to 0x1 to switch this pin to input mode.

The registers [CONTROL\\_PADCONF\\_WAKEUPEVENT\\_0](#) through [CONTROL\\_PADCONF\\_WAKEUPEVENT\\_6](#) are dedicated 32 bit registers for a separate capture of the WAKEUPEVENT from different PADs. Duplication of the wake-up event bits CONTROL\_CORE\_PAD0\_X\_PAD1\_Y[31,15] and CONTROL\_WKUP\_PAD0\_X\_PAD1\_Y[31,15] inside these 7 additional registers helps reduce the software latency in identifying which PAD has triggered a wake-up event.

### 18.4.8.4.2 I/O Power Optimization

To optimize I/O power, it is important to avoid unconnected or incorrectly pulled pins. According to the type of pins, the way to reduce power consumption can differ. Table 18-10 shows the three available pin (or ball) types.

**Table 18-10. Pin Types**

Input	Output	Bidirectional
 <p>sysctrl-011</p>	 <p>sysctrl-012</p>	 <p>sysctrl-013</p>

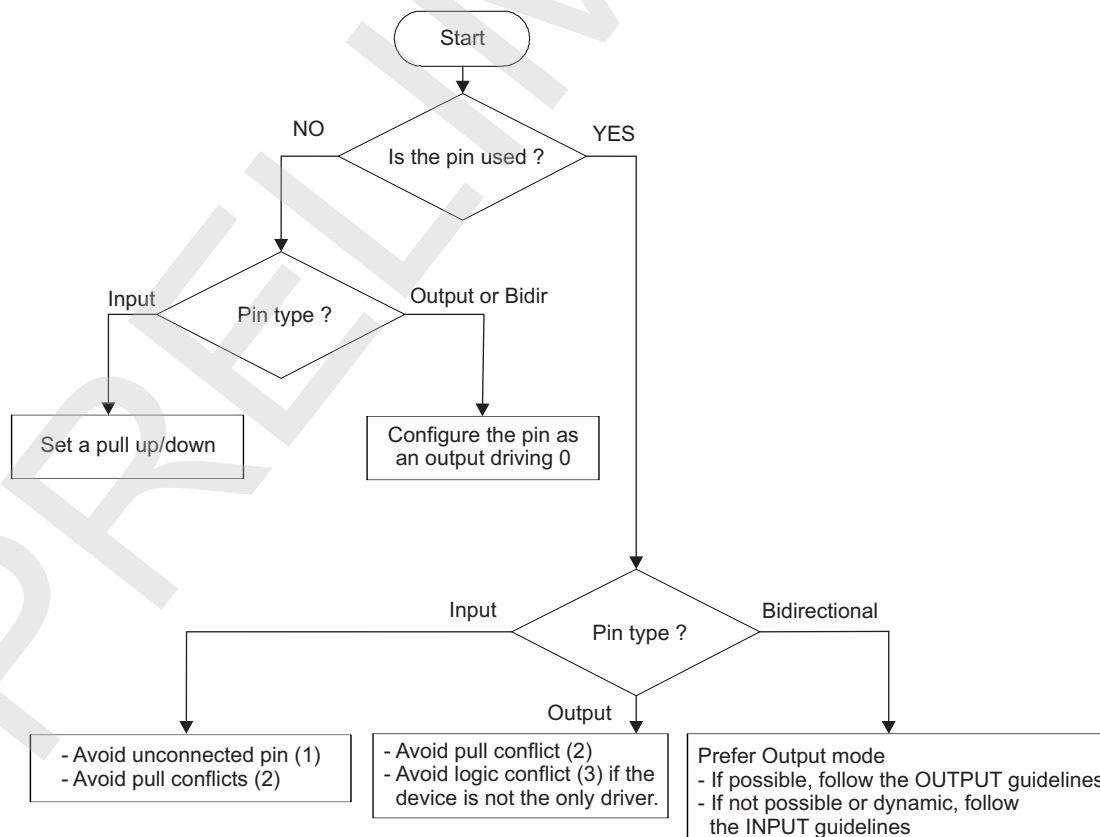

The configuration differs according to the I/O cell types. The following advices can be useful to avoid extra current leakage:

- For input pins, use a pullup/down when possible.
- For output pins, check existing pulls to avoid conflicts.
- For bidirectional pins, reconfigure the pin as an output driving 0 when possible.

Some I/O configurations involve modifications during the software setup of I/Os and sometimes require several hardware updates.

Figure 18-10 shows how to optimize the power consumption of pads.

**Figure 18-10. I/O Power Optimization Flow Chart**

sysctrl-014

The following notes give additional explanation about the pin configuration.

1. To avoid unconnected pins, the configuration depends on its use:
  - If the pin is not driven externally, a pullup / pulldown is required.
  - Otherwise, a pullup/down is not necessary.
2. Pull conflicts occur when there are different pulls on the same line. To correctly configure the pin, avoid external and internal pull together.
3. Logic conflicts consist in different electrical levels at the same time on one line. This can occur when several devices are connected to the same line. The two possible cases are:
  - If no external device drives the line, configure the pin to drive a 0.
  - If another device drives the line, either the same value must be driven or the pin must be disconnected (high-impedance state - HiZ).

---

**NOTE:** It is advised to use high impedance logical state either on the device or the external component when the line is driven by both components.

---

### 18.4.9 Extended-Drain I/O and PBIAS Cell

The device mainly supports 1.8-V I/O voltage on its interfaces, with the exception of MMC/SD/SDIO1 interface, which supports both 1.8-V and 3.0-V voltages. The need for embedded extended-drain I/Os on MMC/SD/SDIO1 interface imposes the use of embedded PBIAS cell MMC1\_PBIAS to provide a 1.8-V or 3.0-V reference.

A second PBIAS cell (PBIAS1) is integrated in the device. One of its associated extended-drain I/O cells operates signals of the gpio\_wk0 through gpio\_wk2 I/Os.

A separate extended-drain I/O cell (USBC1\_ICUSB extended-drain I/O cell) is shared between usbc1\_icusb\_dp, usbc1\_icusb\_dm (Muxmode = 0x0), and gpio98 and gpio99 (MuxMode = 0x3) pads. The USBC1\_ICUSB I/O cell and the gpio\_wk\_0-gpio\_wk\_2 extended-drain I/O cells are biased by the same PBIAS1 output voltage.

---

**NOTE:** With the appropriate PBIAS cell configuration, the different I/Os muxed on the sdmmc1, usbc1\_icusb and gpio\_wk0 through gpio\_wk2 pads can operate at 1.8V or 3V-power supply.

---

The MMC1\_PBIAS cell and its associated MMC1 extended-drain I/O is software-controlled by bits in the [CONTROL\\_PBIASLITE](#) and [CONTROL\\_MMC1](#) registers of the device core control module. For descriptions of these registers, see [Table 18-570](#) and [CONTROL\\_MMC1](#) in [Section 18.6.6](#), [SYSCTRL\\_PADCONF\\_CORE Register](#). PBIAS1 and associated GPIO\_WKx and USBC1\_ICUSB\_x I/Os are software-controlled by bits in the [CONTROL\\_PBIASLITE](#), [CONTROL\\_MMC1](#), and [CONTROL\\_GPIOWK](#) registers. For descriptions of these registers, see [Table 18-570](#), [CONTROL\\_MMC1](#) in [Section 18.6.6](#), [SYSCTRL\\_PADCONF\\_CORE Register Summary](#), and [CONTROL\\_GPIOWK](#) in [Section 18.6.9](#), [SYSCTRL\\_PADCONF\\_WKUP Register Description](#).

[Figure 18-11](#) shows the functional block diagram with the connections between the PBIAS cells and the extended-drain I/O cells.

Figure 18-11. Functional Block Diagram

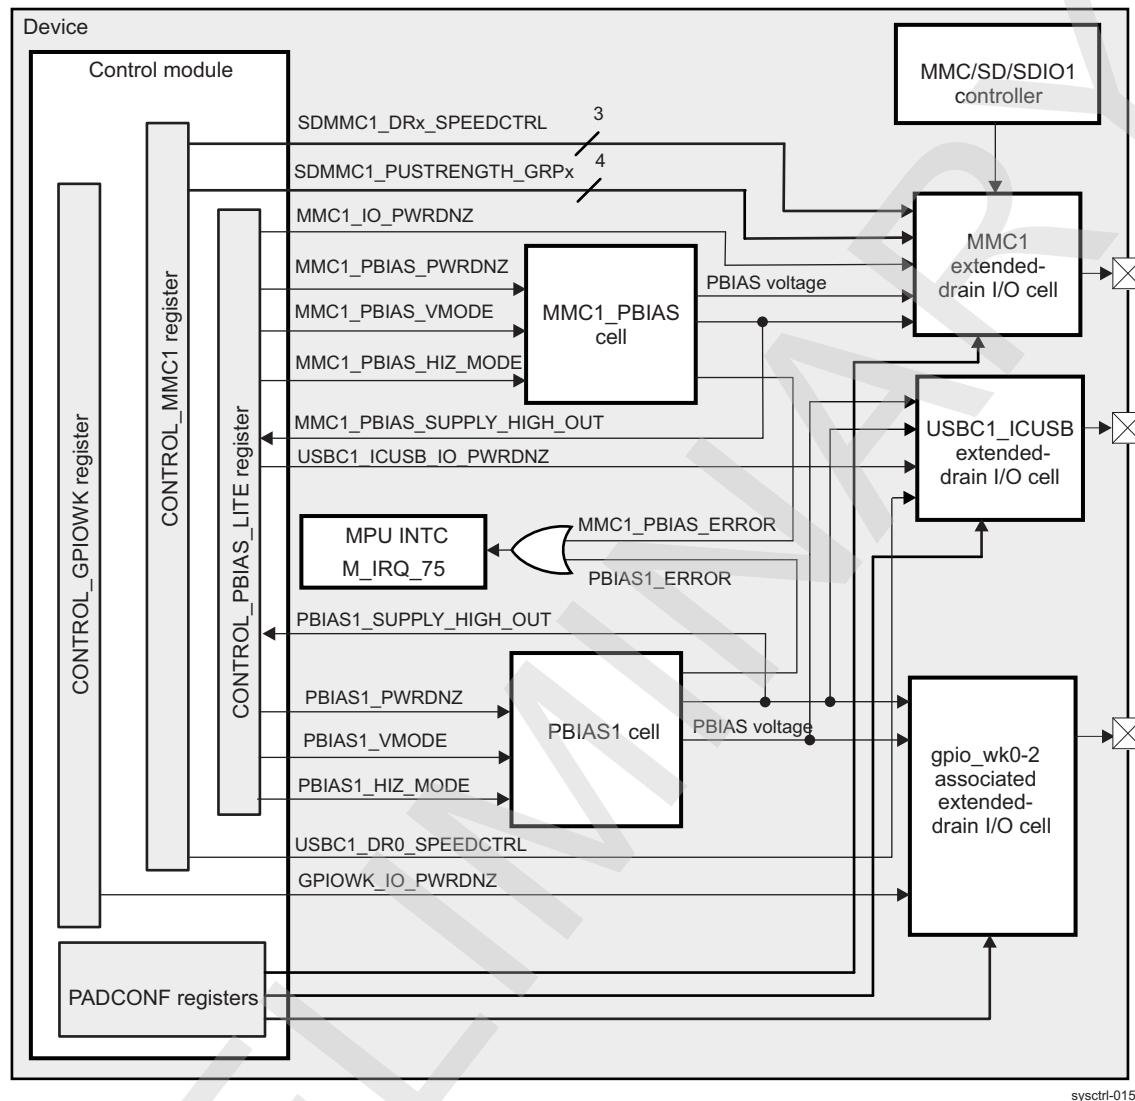

Table 18-11. PBIAS Cell and Extended-Drain I/O Pin CONTROL\_PBIAS\_LITE Bit control

Control Signals for Different PBIAS and Extended-Drain I/O Cells	Description
MMC1_PBIAS_PWRDNZ	Protects the MMC1_PBIAS cell when the SDMMC1_VDDS supply voltage is not stable. Software must keep this signal to 0b0 whenever this voltage is ramping up/down or changing.  When this bit is at 0, the PBIAS output voltage is equal to SDMMC1_VDDS voltage and the PBIAS supply detector is disabled.
MMC1_PBIAS_VMODE	Sets the SDMMC1_VDDS voltage level (MMC1_PBIAS side) according to which MMC1_PBIAS cell generates appropriate biasing levels for the MMC1 extended-drain I/O. The default state of this bit is HIGH, indicating that the voltage level SDMMC1_VDDS is 3.0 V.
MMC1_PBIAS_HIZ_MODE	When MMC1_PBIAS_HIZ_MODE is set to 1 the PBIAS output is in high impedance. MMC1_PBIAS_ERROR is automatically set to 1, when MMC1_PBIAS_HIZ_MODE = 1. When MMC1_PBIAS_HIZ_MODE = 0, MMC1_PBIAS cell is in normal operation mode.
MMC1_PBIAS_SUPPLY_HIGH_OUT	Output from the internal MMC1_PBIAS voltage supply detector, which describes whether the SDMMC1_VDDS supply is 3.0 V or 1.8 V.

**Table 18-11. PBIAS Cell and Extended-Drain I/O Pin CONTROL\_PBIAS\_LITE Bit control  
(continued)**

<b>Control Signals for Different PBIAS and Extended-Drain I/O Cells</b>	<b>Description</b>
MMC1_PBIAS_ERROR	Indicates whether the software-programmed MMC1_PBIAS_VMODE level matches the MMC1_PBIAS_SUPPLY_HI_OUT output signal during normal operation.
MMC1_IO_PWRDNZ	Protects the MMC1 I/O extended-drain cell when the SDMMC1_VDDS voltage is not stable. Software must keep this signal to 0b0 whenever the SDMMC1_VDDS supply voltage is ramping up/down or changing. When this bit is at 0, the pad is floating.
SDMMC1_DRx_SPEEDCTRL, x = (0..2)	Speed control signals for three different SDMMC1 pad groups identified within the MMC1 I/O cell
SDMMC1_PUSTRNGTH_GRPx, x = (0..3)	Pullup strength controls for four different SDMMC1 pad groups identified within the MMC1 I/O cell
PBIAS1_PWRDNZ	Protects the PBIAS1 cell when the SIM_VDDS supply voltage is not stable. Software must keep PWRDNZ signal to 0b0 whenever this supply voltage is ramping up/down or changing.  When this bit is at 0, the PBIAS1 output voltage is equal to SIM_VDDS voltage and the PBIAS supply detector is disabled.
PBIAS1_VMODE	Sets the SIM_VDDS voltage level (PBIAS1 side) according to which PBIAS1 cell generates appropriate biasing levels for the GPIOWK0GPIOWK2 and USBC1_ICUSB associated extended-drain I/Os. The default state of this bit is HIGH, indicating that the voltage level SIM_VDDS is 3.0 V.
PBIAS1_HIZ_MODE	When PBIAS1_HIZ_MODE is set to 1 the PBIAS1 output is in HIGH impedance. PBIAS1_ERROR is automatically set to 1, when PBIAS1_HIZ_MODE = 1.  When PBIAS1_HIZ_MODE = 0, PBIAS1 is in normal operation mode.
PBIAS1_SUPPLY_HIGH_OUT	Output from the internal PBIAS1 voltage supply detector, which describes whether the SIM_VDDS supply is 3.0 V or 1.8 V.
PBIAS1_ERROR	Indicates whether the software-programmed PBIAS1_VMODE level matches the PBIAS1_SUPPLY_HI_OUT output signal during normal operation
GPIOWK_IO_PWRDNZ	Protects the GPIOWK0GPIOWK2 associated extended-drain I/O cell when the SIM_VDDS voltage is not stable.  Software must keep this signal to 0b0 whenever the SIM_VDDS supply voltage is ramping up/down or changing. When this bit is at 0, the pad is floating.
PAD_GPIO_WK1_LOW	This signal should be set to 0b0 to disable the strong pulldown available after reset on the gpio_wk1 pad. This is to ensure normal use of the gpio_wk1 pad.
0.22 PAD_GPIO_WK2_LOW	This signal should be set to 0b0 to disable the strong pulldown available after reset on the gpio_wk2 pad. This is to ensure normal use of the gpio_wk2 pad.
0.23 USBC1_ICUSB_IO_PWRDNZ	Protects the USBC1_ICUSB extended-drain I/O cell when the SIM_VDDS voltage is not stable. Software must keep this signal to 0b0 whenever the SIM_VDDS supply voltage is ramping up/down or changing.  When this bit is at 0, the pad is floating.
0.24 USBC1_DR0_SPEEDCTRL	Speed controls for the ICUSB pads associated with the USBC1_ICUSB associated I/O cell

**NOTE:** When HIZ\_MODE = 1, the PBIAS output (pbias\_mmc1 pin) must be tied to a defined external potential to avoid stress on transistors.

Table 18-12 lists the power supplies for PBIAS and the extended-drain I/O cells.

**Table 18-12. Power Supplies**

<b>Name</b>	<b>Description</b>
VDD2	Core voltage supply
SDMMC1_VDDS	MMC1 I/O cell supply voltage nominal 1.8 V/3.0 V
SIM_VDDS	USBC1_ICUSB and GPIOWK I/O cell supply voltage nominal 1.8 V/3.0 V
VDDS	1.8-V supply for the input buffer

### 18.4.9.1 PBIAS Cell

The MMC1\_PBIAS cell provides a bias for the the MMC/SD/SDIO1 extended-drain I/O cell used with high voltage for the MMC/SD/SDIO1 interface. This PBIAS cell provides a voltage reference (PBIAS voltage) for biasing extended drain in the MMC/SD/SDIO1 cell. In addition to generating the bias voltage, the cell can detect the supply voltage (SDMMC1\_VDDSD) value (1.8 V or 3.0 V) and update, with its status, the [CONTROL\\_PBIASLITE](#)[24] MMC1\_PBIASLITE\_SUPPLY\_HI\_OUT bit. However, this is possible when voltage has reached its steady state (the internal PBIAS voltage detector is only enabled when the MMC1\_PBIAS\_PWRDNZ signal is set to 0b1).

The PBIAS1 cell provides a reference voltage for biasing the gpiowk0gpiowk2 associated extended-drain I/O cell and the USBC1\_ICUSB extended-drain I/O cell. In addition to generating the bias voltage, the cell can detect the supply voltage (SIM\_VDDSD) value (1.8 V or 3.0 V) and update, with its status, the [CONTROL\\_PBIASLITE](#)[30] PBIASLITE1\_SUPPLY\_HI\_OUT bit. However, this is possible when voltage has reached its steady state (the internal PBIAS voltage detector is enabled only when the PBIAS1\_PWRDNZ signal is set to 0b1).

#### CAUTION

A PBIAS cell lets the peripheral associated to its corresponding extended-drain I/O cells support 1.8-V and 3.0-V voltages. A PBIAS cell is not a part of a peripheral, but a part of the device I/Os to which this peripheral is internally connected. These device I/Os are not exclusive to one peripheral; through I/O multiplexing they can be connected to other internal signals. It is necessary to configure the PBIAS to enable the I/Os, regardless of how I/O multiplexing is configured for these device I/Os. In other words, independently of which signal is internally connected to a device I/O powered by SDMMC1\_VDDSD or SIM\_VDDSD, the corresponding PBIAS must be configured.

### 18.4.9.2 Extended-Drain I/O

The following MMC/SD/SDIO1 interface signals (selected when MuxMode = 0) use the device I/Os associated with the MMC1 extended-drain I/O cell:

- sdmmc1\_clk
- sdmmc1\_cmd
- sdmmc1\_dati (where i = 0 to 7)

The MMC1 I/O cell is powered externally through the vdds\_sdmmc1 pad.

---

**NOTE:** The MMC1 I/O cell associated device I/Os are also shared with other signals. gpio100gpio109, etc. are available when MuxMode is different than 0x0. If signals other than sdmmc1\_x are selected, the MMC1 I/O cell must also be configured.

---

For more information about signal multiplexing, see [Table 18-9](#).

For GP device I/Os, which are part of the GPIOWK pads associated extended-drain cell, Muxmode = 3 as well as Muxmode=6 are functional.

With Muxmode set to 0x3, the following signals are present:

- gpio\_wk0
- gpio\_wk1
- gpio\_wk2

With Muxmode set to 0x6, the output signals hw\_dbg1, hw\_dbg2 and hw\_dbg3 are present at the gpio\_wk0, gpio\_wk1 and gpio\_wk2 pads, respectively.

This PBIAS1 associated extended-drain I/O cell is externally powered through the vdds\_sim pad.

**NOTE:** The GPIOWK associated I/O cell should be properly configured when gpiowk0gpiowk2 pads are used. For more information about signal multiplexing, see [Table 18-9](#).

The following USBC1\_ICUSB interface signals (selected through MuxMode = 0) use the device I/Os associated with the USBC1\_ICUSB extended-drain I/O cell:

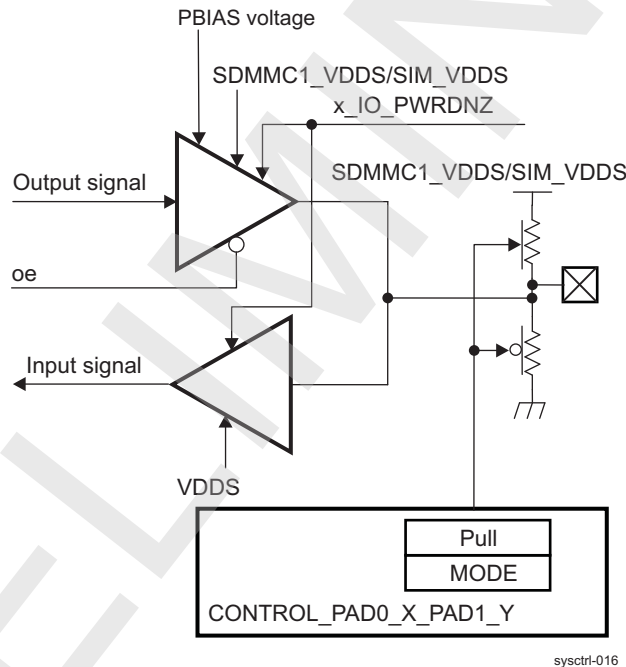

- usbc1\_icusb\_dp
- usbc1\_icusb\_dm

The USBC1\_ICUSB I/O cell uses the same external power supply voltage as the GPIOWK cell (vdds\_sim pad).

**NOTE:** The USBC1\_ICUSB I/O cell associated device I/Os are also shared with gpio\_98 and gpio\_99 signals, when MuxMode is equal to 0x3. USBC1IC\_ICUSB cell must be configured to allow for gpio\_98 - gpio\_99 operation. For more information about signal multiplexing, see [Table 18-9](#).

Figure 18-12 describes the extended-drain I/O cells.

**Figure 18-12. Extended-Drain I/O**

The extended-drain I/O cells have the following I/O signals:

- Output signal, input signal, and oe, which comes from the selected I/O module with the correctly configured MUXMODE field within the corresponding CONTROL\_CORE\_PAD0\_X\_PAD1\_Y or CONTROL\_WKUP\_PAD0\_X\_PAD1\_Y register.

**NOTE:** Extended-drain I/Os are muxed I/Os with mode and pullup/pulldown configurations programmable in the control module.

- The PBIAS voltage is a voltage reference for biasing the extended-drain in the MMC1, USBC1\_ICSUB, and GPIOWK I/O cells.
- The PWRDNZ signals are used to protect the I/O cells when the SDMMC1\_VDDS/SIM\_VDDS voltage is not stable.

**CAUTION**

Software must keep the PWRDNZ related signals to 0b0 whenever the SDMMC1\_VDDDS or SIM\_VDDDS signal is ramping up/down or changing. When it is 0, the pad is floating (the pad may not reflect the state of the output signal, and the input signal may not reflect the state of the pad).

- The [CONTROL\\_PBIASLITE](#)[24] MMC1\_PBIASLITE\_SUPPLY\_HI\_OUT bit is a status bit on the SDMMC1\_VDDDS value and is used to inform the MMC1 I/O cell about the value of the SDMMC1\_VDDDS signal.
- The [CONTROL\\_PBIASLITE](#)[30] PBIASLITE1\_SUPPLY\_HI\_OUT bit is a status bit on the SIM\_VDDDS value and is used to inform the gpiowk0gpiowk2 associated I/O cell and USBC1\_ICUSB I/O cell about the value of the SIM\_VDDDS signal.

For more information about the software configurations of the extended drain I/Os and PBIAS cells, see [Section 18.5.1.2.2, Extended Drain I/Os and PBIAS Cells Programming Guide](#).

**NOTE:** The device can be supplied by an external power IC. TI provides such a global solution to its customers with the TWL60xx power IC.

If the device is associated with the TWL60xx power IC, before using an extended-drain I/O interface, software must program the TWL60xx to enable the VMMC1 (for the MMC/SD/SDIO1 or muxed I/O modules) or VSIM (for the GPIOWK0, GPIOWK2, USBC1\_ICUSB, or muxed I/Os) and the LDO to provide a 1.8-V/3.0-V voltage. This is done by software through the I<sup>2</sup>C interface that links the device and TWL60xx IC.

**CAUTION**

The power supply voltage generated from the companion power IC and applied on the vdds\_sdmmc1 or vdds\_sim device pins must be programmed according to the recommendations for the currently selected I/O module power supply range.

If the application does not want the I/O interface running at 3.0 V, software users must then assert the VMODE signal to low for 1.8-V activity: in this case, the PBIAS is connected to ground.

[Table 18-13](#) lists the control signal with the corresponding control bits from the [CONTROL\\_PBIASLITE](#), [CONTROL\\_MMC1](#), and [CONTROL\\_GPIOWK](#) registers to configure the PBIAS and the extended-drain I/O cells. These signals can be software-controlled.

**Table 18-13. PBIAS/Extended-Drain I/O Cells Control Signals**

Control signals for Different PBIAS and Extended-Drain I/O Cells	Bits used for PBIAS Cell and I/O Cell Configurations for Different I/O Modules	Reset Value
MMC1_PBIAS_PWRDNZ	<a href="#">CONTROL_PBIASLITE</a> [22] MMC1_PBIASLITE_PWRDNZ	0

PAD_GPIO_WK2_LOW	CONTROL_GPIOWK[29] PAD_GPIO_WK2_LOW	1
USBC1_ICUSB_IO_PWRDNZ	CONTROL_PBIASLITE[20] USBC1_ICUSB_PWRDNZ	0
USBC1_DR0_SPEEDCTRL	CONTROL_MMC1[24] USBC1_DR0_SPEEDCTRL	0

The two PBIAS cells support two ranges of I/O SDMMC1\_VDDS/ SIM\_VDDS: 1.8 V, typical for low-voltage applications, and 3.0 V, typical for high-voltage applications. For each supply voltage range, the cell generates suitable bias voltage (PBIAS) for extended-drain PMOS devices.

**CAUTION**

The PBIAS cell must be programmed according to peripheral power supply voltage. See [Table 18-14](#).

**Table 18-14. Voltage Configuration<sup>(1)</sup>**

PBIASLITEVMODE Configuration	SDMMC1_VDDS/SIM_VDDSVoltage	Type of Operation
1.8 V	1.8 V	Normal 1.8-V operation
1.8 V	3.0 V	Damaging configuration <sup>(2)</sup>
3.0 V	1.8 V	Degraded functionality <sup>(2)</sup>
3.0 V	3.0 V	Normal 3.0-V operation

<sup>(1)</sup> For damaging configuration, hardware system protection is provided to prevent deterioration of the associated extended-drain I/Os.

<sup>(2)</sup> It is forbidden to use these modes.

The PBIAS output voltage is the same as SDMMC1\_VDDS / SIM\_VDDS voltage when the corresponding PWRDNZ bit is low. Once the SDMMC1\_VDDS / SIM\_VDDS supply is stable, software can release the PWRDNZ (setting it high). This then starts up the PBIAS cell work to generate the PBIAS voltage. During the completion process the corresponding I/Os cannot be used for transmitting data. If VMODE is set correctly, (compared with supply detector output and found to be the same), then PBIAS output voltage is generated based on the value of VMODE.

**NOTE:** In the case of a damaging configuration, hardware system protection prevents deterioration of the associated extended-drain I/Os.

**CAUTION**

The following requirements are critical for an extended-drain I/O cell:

- The VMODE bit must be defined before the PWRNDZ bit is made HIGH (cell is brought out of power-down mode).
- The default state of VMODE bit is HIGH (indicates 3.0-V operation).
- PWRNDZ bit must be kept LOW whenever the SDMMC1\_VDDS/SIM\_VDDS supply is ramping up/down or changing. This could be damaging.
- Supply detector is disabled when PWRDNZ = 0 and in this case supply detector output (SUPPLY\_HI\_OUT) is initialized to 0.

**18.4.9.3 PBIAS Error Generation**

If VMODE and supply detector outputs are unequal. It takes 4 microseconds for the comparator to process the inputs and generate VMODE\_ERROR flag.

Table 18-15 summarizes the generation of the PBIAS error signals - MMC1\_PBIAS\_ERROR of the MMC1\_PBIAS cell and PBIAS1\_ERROR of the PBIAS1 cell. They depend on the various CONTROL\_PBIASLITE bits combinations. The shaded row is a potential condition that could cause a reliability issue if not detected. To prevent this reliability issue, the PBIAS voltage is tied to SDMMC1\_VDDS/SIM\_VDDS when the PBIAS error signal is HIGH. This disables the IOs.

**CAUTION**

Although asserting VMODE\_ERROR to 1 provides that PBIAS voltage is equal to SDMMC1\_VDDS/SIM\_VDDS, this does not completely protect the IO cells. It is also recommended that all the I/Os are powered down, setting the corresponding I/O cells PWRDNZ mode bits to 0b0 by software as soon as VMODE\_ERROR=0b1.

**Table 18-15. PBIAS Error Signal Truth Table**

VMODE	PWRDNZ	HIZ_MODE	SUPPLY_HI_OUT	VMODE_ERROR
0	0	X	0	0
0	1	0	0	0
0	1	0	1	1
X	1	1	X	1
1	0	X	0	0
1	1	0	0	1
1	1	0	1	0

**NOTE:** VMODE\_ERROR =0b1: VMODE level is not the same as SUPPLY\_HI\_OUT or high impedance mode (HiZ) is selected.

VMODE\_ERROR = 0b0: VMODE level is the same as SUPPLY\_HI\_OUT or VMODE not considered (PWRDNZ=0b0)

The MMC1\_PBIAS\_ERROR and PBIAS1\_ERROR signals are ORed and the outputs mapped to the MPU subsystem interrupt controller (INTC). The interrupt line MA\_IRQ\_75 is activated upon error occurrence. For more information about the Cortex-A9 MPU interrupt controller registers and their description, see the *ARM Cortex-A9 Technical Reference Manual*.

The CONTROL\_PBIASLITE[29] PBIASLITE1\_VMODE\_ERROR bit and the CONTROL\_PBIASLITE[23] MMC1\_PBIASLITE\_VMODE\_ERROR bit also indicates whether this kind of error occurs.

#### 18.4.9.4 Critical Timing Requirements

It is crucial that the PBIAS and I/O cell related PWRDNZ bits are deasserted (made 1 from 0) only after SDMMC1\_VDDS/SIM\_VDDS power supply voltage is stable in the device. The cells support only the case when 1.8-V input buffer supply voltage VDDS ramps up before VDD2 (core voltage). This power-up sequence is automatically provided upon power-on reset by hardware in the device. Care must be taken that the externally provided SDMMC1\_VDDS/SIM\_VDDS voltage (1.8 V/ 3 V) be powered up, only after both VDD2 and VDDS have reached their steady state.

Figure 18-13 shows the only possible power-up sequence, as well as the expected behavior of PWRNDZ mode related bits with regard to supplying voltages ramp up.

**Figure 18-13. VDDS Ramps Up Before VDD2**

#### 18.4.10 Band Gap Voltage and Temperature Sensor

The device supplies a voltage reference and a temperature sensor feature which are gathered in the band gap voltage and temperature sensor (VBGAPTS) module. The band gap provides current and voltage reference for its internal circuits and also to other analog IP blocks. The analog-to-digital converter (ADC) produces an output value that is proportional to the silicon temperature.

Main features of the BGAPTS module are:

- A constant voltage reference output: 0.5 V
- Four constant current reference outputs of 1microAmp.
- Analog supply is a nominal 1.8 V.
- Small ADC with 8-bit digital output
- Off mode compatible
- Thermal shutdown comparator output

The band-gap and the temperature sensor are software-controlled by bits in the register [CONTROL\\_TEMP\\_SENSOR](#) within the SYSCTRL\_GENERAL\_CORE module instance. See [Table 18-192](#), for the description of this register.

Figure 18-14 shows the functional block diagram of the band gap and the temperature sensor module.

Figure 18-14. Functional Block Diagram

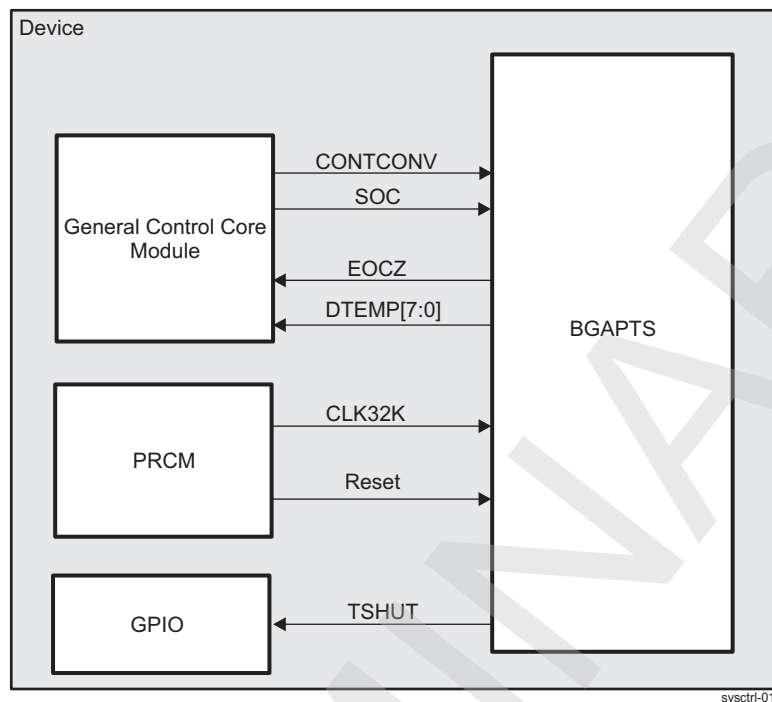

Table 18-16 describes the input and output signals for the BGAPTS module.

Table 18-16. Band Gap Voltage and Temperature Sensor Signal Description

Pin	I/O <sup>(1)</sup>	Description
SOC	I	Start Of Conversion signal. A transition to high starts a new ADC conversion cycle.
EOCZ	O	End of Conversion signal. When low, the signal indicates that the value of DTEMP[7:0] is valid.
DTEMP[7:0]	O	Temperature data from the temperature sensor. This value is valid when EOCZ is low.
CONTCONV	I	Configures the temperature sensor in continuous conversion mode. 0: ADC single conversion mode 1: ADC continuous conversion mode
TSHUT	O	Thermal shutdown comparator output. The signal is low during normal operation and goes high during a thermal shutdown event.
CLRZ	I	When low the temperature sensor is in reset mode. This signal must be LOW when OFFMODE is HIGH.
CLK32K	I	32-kHz functional clock from the CORE power domain used by the temperature sensor during temperature conversion.

<sup>(1)</sup> I=Input, O=Output

All the configuration signals are available through the [CONTROL\\_TEMP\\_SENSOR](#) register.

**NOTE:** VBGAPTS CLK32K is used only for the temperature sensor. When ADC is not converting, this clock can be switched OFF (CLK32K = 0). In this case, DTEMP[7:0] retains the temperature code obtained at the previous conversion.

#### 18.4.10.1 Band Gap Voltage Reference

The band gap voltage reference feature provides several constant voltage and current references for its internal circuits, but also for other analog modules.

The voltage reference signal is a 0.5-V output which is internally used by the module and that is exported for external modules or for tests.

The current reference signals consist in four lines, each of which generates a 1- $\mu$ A current with a 1.8-V voltage. These lines can be used to bias other modules.

### 18.4.10.2 Temperature Sensor

The temperature sensor feature is used to convert the temperature of the device into a decimal value coded on 8 bits. An internal ADC is used for conversion. The recommended operating temperatures must be in the range ( $-40^{\circ}\text{C}$  to  $125^{\circ}\text{C}$ ) for standard conversion, and can go up to  $160^{\circ}\text{C}$  when using the thermal shutdown comparator output (TSHUT signal). This comparator output is asserted high when temperature of the chip is higher than  $147^{\circ}\text{C}$ . This signal is internally connected to a GPIO pin. See [Chapter 25, General-Purpose Interface](#), for more information.

The temperature sensor offers two operating modes: a single conversion mode and a continuous conversion mode.

#### 18.4.10.2.1 Single Conversion Mode (CONTCONV = 0)

When the ADC is idle ([CONTROL\\_TEMP\\_SENSOR\[8\]](#) BGAP\_TEMP\_SENSOR\_EOCZ = 0) and the [CONTROL\\_TEMP\\_SENSOR\[10\]](#) BGAP\_TEMP\_SENSOR\_CONTCONV bit is set to 0, it is possible to ask for a single temperature conversion. To initiate a new conversion, the start of conversion (SOC) signal should be asserted and maintained high until the end of conversion (EOCZ) signal goes high, after which the SOC should be made low by writing 0 to the [CONTROL\\_TEMP\\_SENSOR\[9\]](#) BGAP\_TEMP\_SENSOR\_SOC bit. Conversion completion is indicated by a negative edge on EOCZ (the [CONTROL\\_TEMP\\_SENSOR\[8\]](#) BGAP\_TEMP\_SENSOR\_EOCZ bit).

The timing sequence for a single temperature conversion is shown in [Figure 18-15](#).

**Figure 18-15. Single Conversion Mode (CONTCONV = 0)**

#### 18.4.10.2.2 Continuous Conversion Mode (CONTCONV = 1)

When the ADC is idle ([CONTROL\\_TEMP\\_SENSOR\[8\]](#) BGAP\_TEMP\_SENSOR\_EOCZ = 0) and the [CONTROL\\_TEMP\\_SENSOR\[10\]](#) BGAP\_TEMP\_SENSOR\_CONTCONV bit is set to 1, it is possible to ask for a continuous temperature conversion. To initiate a new conversion, the SOC signal should be asserted and maintained high until the EOCZ signal goes high, after which the SOC should be made low by writing 0 to the [CONTROL\\_TEMP\\_SENSOR\[9\]](#) BGAP\_TEMP\_SENSOR\_SOC bit. The ADC starts converting continuously, and when a conversion is complete, data is written to the [CONTROL\\_TEMP\\_SENSOR\[7:0\]](#) BGAP\_TEMP\_SENSOR\_DTEMP bit field and EOCZ goes low after four clock cycles.

The timing sequence for a continuous temperature conversion is shown in [Section 18.4.11.1](#).

**Figure 18-16. Continuous Conversion Mode (CONTCONV = 1)****18.4.10.2.3 ADC Codes Versus Temperature**

Table 18-17 gives the temperature range corresponding to each value of the `CONTROL_TEMP_SENSOR[7:0]` `BGAP_TEMP_SENSOR_DTEMP` bit field.

**Table 18-17. ADC Code Versus Temperature**

ADC Code	Temperature °C		ADC Code	Temperature °C		ADC Code	Temperature °C		ADC Code	Temperature °C	
	From	To		From	To		From	To		From	To
0	-40	-40	32	-5	-3.5	64	50	52	96	105	107

### 18.4.11 Hardware Observability

#### 18.4.11.1 Device Internal Signals Observability Overview

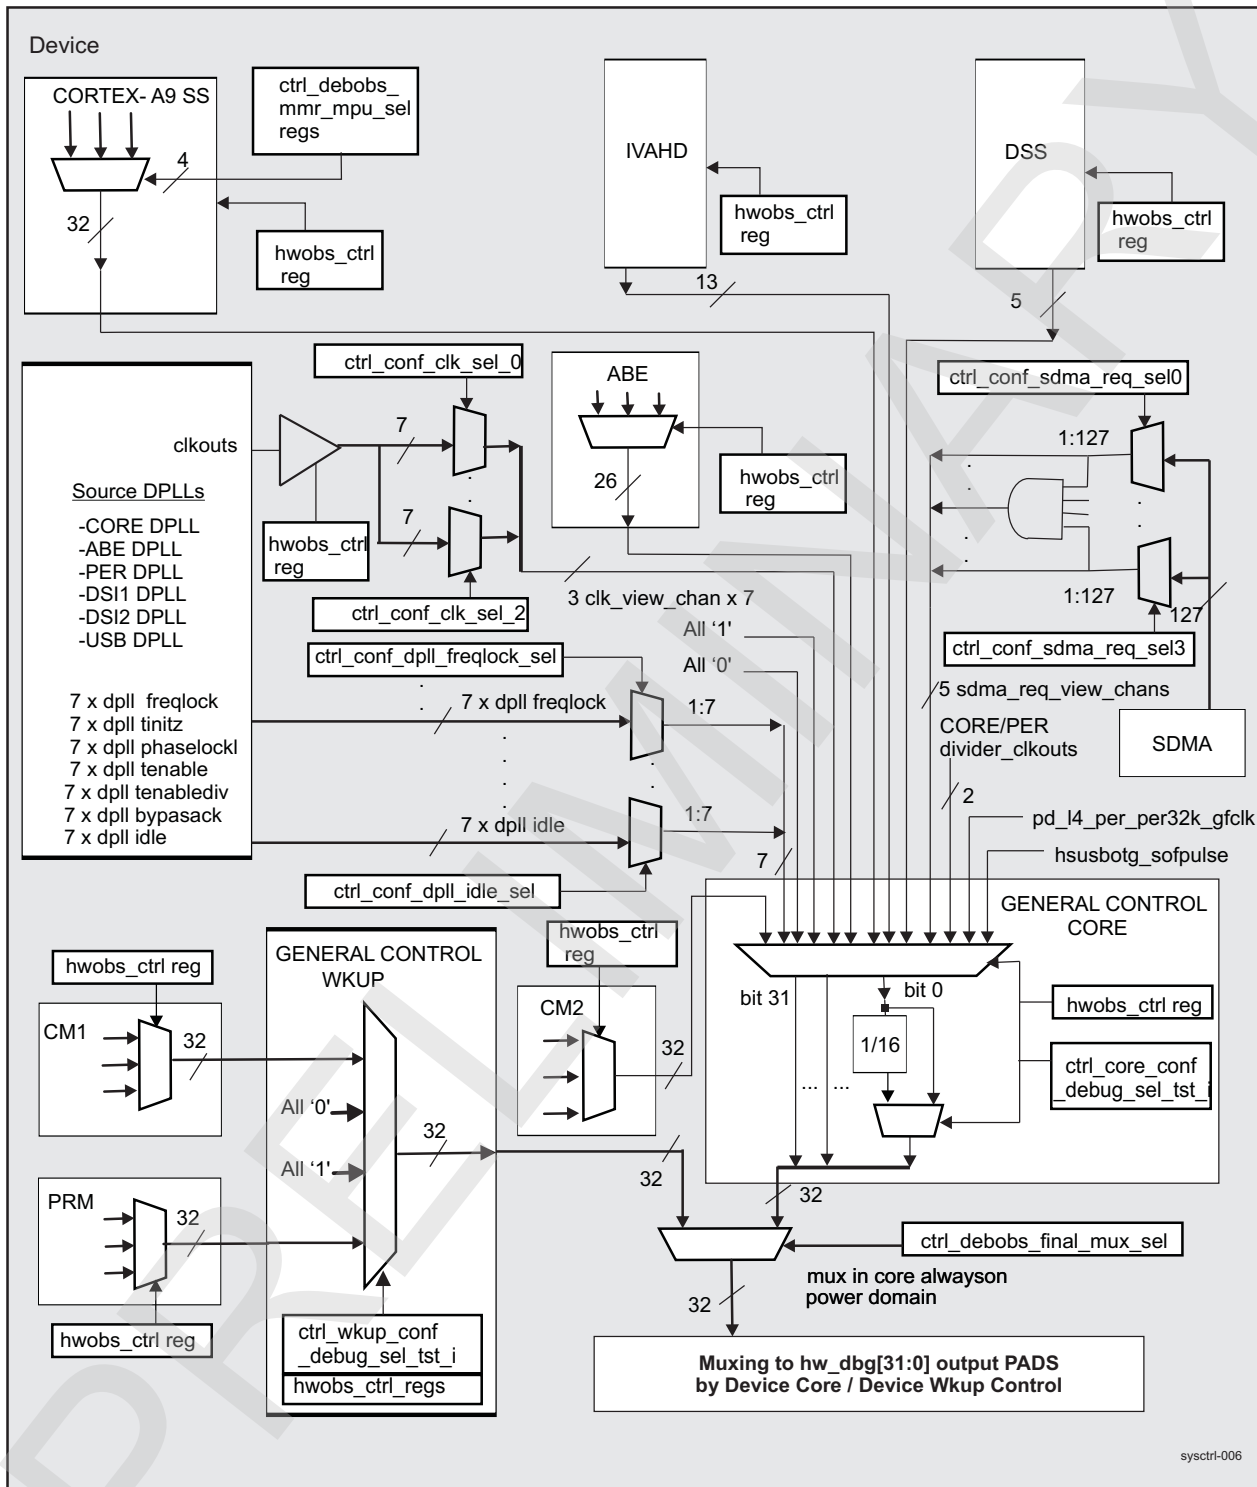

The General Control Module provides observability features covering different module internal signals related to:

- Power and reset management protocol inside different power domains
- Power domain states / transition indication
- Interrupt requests by different modules
- DMA requests by different modules
- Clocks and clock management

The associated signal multiplexing function is controlled through the hardware observability I/O multiplexing registers (32bits read/write registers). The selected signals to be observed are multiplexed to the po\_hw\_dbg[31:0] bus.

Figure 18-17 shows an overview of observability multiplexing, which minimizes the number of signals exchanged at the device boundary.

Figure 18-17. Overview of the Hardware Observability Functionality

#### 18.4.11.2 Observability Gating Capabilities

The programmer has the option to gate all 32 signals of the observability bus simultaneously, keeping

them either tied to 1, programming `CONTROL_HWOBS_CONTROL` [1] `HWOBS_ALL_ONE_MODE` = 0b1, or keeping them tied to 0, programming `CONTROL_HWOBS_CONTROL`[2] `HWOBS_ALL_ZERO_MODE` = 0b1. This can be useful to check the path from hardware observability to external pads. These two bits should be set to 0 to have the observability feature enabled for all observability pads.

Additionally the bit `CONTROL_HWOBS_CONTROL`[0] `HWOBS_MACRO_ENABLE` provides gating feature only to observability signals coming from the following modules (identified in MACRO group): CORTEX-A9 MPU subsystem, IVAHD, display subsystem, CM2 and ABE. When `CONTROL_HWOBS_CONTROL`[0] `HWOBS_MACRO_ENABLE` = 0b0, the associated with MACRO group observability outputs are gated and forced to 0b0.

---

**NOTE:** Do not set the observability gating bits: `CONTROL_HWOBS_CONTROL`[1] `HWOBS_ALL_ONE_MODE` and `CONTROL_HWOBS_CONTROL`[2] `HWOBS_ALL_ZERO_MODE` simultaneously in 1 to avoid undefined states of the observability bus.

---

The clock frequency of the `po_hw_dbg(0)` signal can be optionally divided by 1, 2, 4, 8 or 16 through programming the bit field `CONTROL_HWOBS_CONTROL`[7:3] `HWOBS_CLK_DIV_SEL`.

---

**NOTE:** For enabling observability over `po_hw_dbg(0)` bus line, bit field `CONTROL_HWOBS_CONTROL`[7:3] `HWOBS_CLKDIV_SEL` must be set different than 0. The default value (0) is not enough to see the core or the wkup observability value at pin `hw_dbg0`.

---

The different observable clockout signals can be simultaneously gated at DPLLs outputs through setting the bit `CONTROL_HWOBS_CONTROL`[8] `HWOBS_CLKOBS_GATE_ENABLE` = 0b1. This feature is useful to save power.

### 18.4.11.3 Observability Signals Multiplexing at General Core/Wake-Up Control Level

Most of the observability multiplexers (MACRO/DPLL/sDMA associated) are instantiated inside the General Core Control module, being part of the switchable CORE domain. There are also signal multiplexers instantiated inside General Wakeup Control module (CM1/PRM dedicated), being part of the WAKEUP domain. The 32-bit `CONTROL_DEBOBS_FINAL_MUX_SEL`[31:0] SELECT bit field, instantiated inside the always-on core domain, selects a signal to be observed between the outputs at CORE and the WAKEUP multiplexing level. A bit from this register set to 1 selects to route a signal from CORE domain to a certain `po_hw_dbgn` (n=0,..31) line, and when set to 0 selects to route a signal from WAKEUP domain to the same line. The output of this top level multiplexing is further passed to padconfiguration muxing I/O level inside Device Core Control Module boundaries.

The module and view-channel selection/reduction layer in the CORE domain is configured through the 4-bit field MODE in the 32 x 32-bit registers `CONTROL_CORE_CONF_DEBUG_SEL_TST_0` through `CONTROL_CORE_CONF_DEBUG_SEL_TST_31`. The following modules can be selected as source of observability signals: Cortex-A9 MPU subsystem, IVAHD, display subsystem, CM2 and ABE (MACRO signal sources).

Part of the `CONTROL_CORE_CONF_DEBUG_SEL_TST` registers are responsible for selection of sDMA view channels, different DPLL-clock view channels as well as other signal view channels.

- 3 x DPLL clockout signal view channels
- 7 x DPLL (other than clkout signal) view channels
- 5 x sDMA signal view channels
- 3 x additional clockout view channels monitoring signals sourced from CORE and PER domain clock dividers -`coredivider_clkout3`; `perdivider_clkout4` and `per32k_gfclk`.

[Table 18-18](#) summarizes the internal signals multiplexing schema for each of the 32 `CONTROL_CORE_CONF_DEBUG_SEL_TST` registers.

**Table 18-18. CORE Power Domain Observability Signals Multiplexing**

There is a third 1:N selection layer, which is applied over several signals to route one at a time to a certain view channel output:

- The CONF\_CLK\_SEL0[2:0] MULT through CONF\_CLK\_SEL2[2:0] MULT bit fields control multiplexing of DPLL CLKOUT signals over three parallel DPLL clockout view channels. The signal source of a certain view channel can be selected to be one of 6 DPLLs in the device -g.h. CORE DPLL, ABE DPLL, PER DPLL, DSI1 DPLL, DSI2 DPLL and USB DPLL.
- The register bit fields associated with the 7 different DPLL signal view channels are summarized in [Table 18-19](#). Again, the 3-bit bit field MULT in each of the 7 different registers makes it possible to choose the source of the dpll signal to be one of the following device DPLLs : CORE DPLL, ABE DPLL, PER DPLL, DSI1 DPLL, DSI2 DPLL and USB DPLL .
- There are four independent system dma request view channels, each of which has a dedicated register ([CONTROL\\_CONF\\_SDMA\\_REQ\\_SEL0](#) through [CONTROL\\_CONF\\_SDMA\\_REQ\\_SEL3](#)), with a 7-bit bit field MULT to select one from a total of 127 possible system dma request signals for observation purposes. See [Chapter 16](#), *sDMA Controller* for more details. The fifth channel, sdma\_req\_view\_all, is acquired through applying logical AND reduction over the four currently selected sDMA view channel output signals).

**Table 18-19. DPLL Signal Observability Controls**

Feature	Type	Register/Bit Field/Observability Control	Description
Different domain dpll freqlock observ.	Control	<a href="#">CONTROL_CONF_DPLL_FREQLOCK_SEL</a> [2:0] MULT	Select DPLL freqlockview channel(1:8)
Different domain dpll phaselock observ.	Control	<a href="#">CONTROL_CONF_DPLL_PHASELOCK_SEL</a> [2:0] MULT	Select DPLL phaselockview channel(1:8)

**Table 18-19. DPLL Signal Observability Controls (continued)**

Feature	Type	Register/Bit Field/Observability Control	Description
Different domain dpll tinitz observ.	Control	<a href="#">CONTROL_CONF_DPLL_TINITZ_SEL</a> [2:0] MULT	Selects to observe DPLL tinitzview channel (1:8)
Different domain dpll tenable observ.	Control	<a href="#">CONTROL_CONF_DPLL_TENABLE_SEL</a> [2:0] MULT	Selects to observe DPLL tenableview channel (1:8)
Different domain dpll tenablediv observ.	Control	<a href="#">CONTROL_CONF_DPLL_TENABLEDIV_SEL</a> [2:0] MULT	selects to observe DPLL tenabledivview channel (1:8)
Different domain dpll bypassack observ.	Control	<a href="#">CONTROL_CONF_DPLL_BYPASSACK_SEL</a> [2:0] MULT	selects to observe DPLL bypassackview channel (1:8)
Different domain dpll idle observ.	Control	<a href="#">CONTROL_CONF_DPLL_IDLE_SEL</a> [2:0] MULT	selects to observe DPLL idlview channel (1:8)

The [CONTROL\\_WKUP\\_CONF\\_DEBUG\\_SEL\\_TST\\_i](#)[0] MODE bit field (i=0..31) provides the option to choose between the observation of device Power and Reset Manager signals or observation of Clock Manager 1 related signals. If [CONTROL\\_WKUP\\_CONF\\_DEBUG\\_SEL\\_TST\\_i](#)[0] =0b1, the hwobs\_int\_prm\_i signal is selected. Otherwise the hwobs\_int\_cm1\_i signal is outputted.

#### 18.4.11.4 Observability Signals Multiplexing at Device Core Control Level

The pads used for the hardware debug must be properly configured by selecting the hardware debug function (hw\_dbgn) of the pad. To map the hw\_dbg0 through hw\_dbg19 signals to their associated external device pins, set the related MUXMODE fields within [CONTROL\\_CORE\\_PAD0\\_SYS\\_BOOT5\\_PAD1\\_DPM\\_EMU0](#) through [CONTROL\\_CORE\\_PAD0\\_DPM\\_EMU19](#) padconfiguration registers to 0b110 (Mode 6). To make the remaining signals: hw\_dbg20 through the hw\_dbg31 available at their corresponding chip outputs, set the MUXMODE fields within [CONTROL\\_CORE\\_PAD0\\_CAM\\_GLOBALRESET\\_PAD1\\_USBB1\\_ULPITLL\\_CLK](#) through [CONTROL\\_CORE\\_PAD0\\_USBB1\\_ULPITLL\\_DAT7\\_PAD1\\_USBB1\\_HSIC\\_DATA](#) padconfiguration registers to 0b110 (Mode 6).

To have hw\_dbg1 through hw\_dbg13 signals multiplexed on WAKEUP domain- pads, one should set MuxMode=0x6 in the following SYSCONF\_PADCONF\_WKUP registers:

- [CONTROL\\_WKUP\\_PAD0\\_GPIO\\_WK0\\_PAD1\\_GPIO\\_WK1](#) through [CONTROL\\_WKUP\\_PAD0\\_GPIO\\_WK2\\_PAD1\\_GPIO\\_WK3](#)[31:16] to have hw\_dbg1 - hw\_dbg4 signals output on the gpio\_wk0 - gpio\_wk3 device pads, respectively.
- [CONTROL\\_WKUP\\_PAD0\\_GPIO\\_WK4\\_PAD1\\_SR\\_SCL](#) [15:0] to have hw\_dbg5 signal output on the gpio\_wk4 device pad.
- [CONTROL\\_WKUP\\_PAD0\\_FREF\\_CLK0\\_OUT\\_PAD1\\_FREF\\_CLK3\\_REQ](#) through [CONTROL\\_WKUP\\_PAD0\\_FREF\\_CLK3\\_OUT\\_PAD1\\_FREF\\_CLK4\\_REQ](#) to have hw\_dbg6 - hw\_dbg9 signal output on the fref\_clk0\_out, fref\_clk3\_req, fref\_clk3\_out and fref\_clk4\_req device pads, respectively.
- [CONTROL\\_WKUP\\_PAD0\\_FREF\\_CLK4\\_OUT\\_PAD1\\_SYS\\_32K](#) [15:0] to have hw\_dbg10 signal output on the fref\_clk4\_out device pad.
- [CONTROL\\_WKUP\\_PAD0\\_SYS\\_PWR\\_REQ\\_PAD1\\_SYS\\_PWRON\\_RESET\\_OUT](#) [31:16] to have hw\_dbg11 signal output on the sys\_pwrn\_reset\_out device pad.
- [CONTROL\\_WKUP\\_PAD0\\_SYS\\_BOOT6\\_PAD1\\_SYS\\_BOOT7](#) to have hw\_dbg12 and hw\_dbg13 signals output on the sys\_boot6 and sys\_boot7 device pads, respectively.

See [Table 18-6](#) for more information.

See [Table 18-111](#), *ACTIVE PADS Configuration Points*, for more details on hardware observability configuration.

#### 18.4.11.5 Observability Signals Sourced at Module Level

Observable signals coming from within different device subsystems are mapped to General Core Control and General Wakeup Control observability inputs. Additional multiplexing is also implemented inside some of the observable modules (See [Figure 18-17](#), *Overview of the Hardware Observability Functionality*).

##### 18.4.11.5.1 Dual Cortex-A9 Subsystem Observable Signals

[Table 18-20](#) through [Table 18-27](#) show Cortex-A9 MPUSS observable signals available in 8 multiplexing modes. The mode is selected at General Control Module level through programming the bit field [CONTROL\\_DEBOBS\\_MMR\\_MPU](#)[3:0] SELECT.

**Table 18-20. Observability Signals Multiplexing at Cortex-A9 MPUSS Level - Mode 0**

#### 18.4.11.5.3 Display Subsystem Observable Signals

The DSS observable signals described in [Table 18-29](#) are directly mapped to DSS observability inputs of the SYSCTRL\_GENERAL\_CORE Module, and no additional multiplexing is performed inside the DSS subsystem wrapper.

**Table 18-29. Observability Signals at DSS Subsystem Level**

<b>SYSCTRL_GENERAL_CORE observability inputs tied to signals inside DSS Subsystem</b>	<b>DSS observable signals mapped to SYSCTRL_GENERAL_CORE observability inputs</b>	<b>Signal Description</b>	<b>Logical value meaning</b>
hwobs_dssvenctvdetgp	DSS_VENC_TVDETP	DSS VENC tvdetgp	Active high pulse to detect the TV connection
hwobs_dssdacpwrndaczcvbs_y	DSS_DAC_PWR_DND ACZCVBS/Y	DSS DAC pwrnd dac zcvbs_y - Power down for DAC Y	0:DAC Y put in power-down mode 1:DAC Y put in ACTIVE state

#### 18.4.11.5.4 DSP Subsystem Observable Signals

This information is not available in the public domain

#### 18.4.11.5.5 ABE Subsystem Observable Signals

The Audio - backend observable signals described in [Table 18-30](#) are directly mapped to the ABE dedicated observability inputs - hwobs\_int\_abe[31:0] of the SYSCTRL\_GENERAL\_CORE Module, and no additional multiplexing is performed inside the ABE .

**Table 18-30. Observability Signals at ABE Subsystem Level**

SYSCTRL_GENERAL_CORE observability inputs tied to signals inside Cortex-A9 MPUSS	SYSCTRL_GENERAL_CORE observability inputs tied to signals inside Cortex-A9 MPUSS	Signal Description	Logical value meaning
hwobs_int_abe[31:26]	-	-	-
hwobs_int_abe[25:24]	OPP_DIV	OPP DIVIDER bit[1:0]	-
hwobs_int_abe[23]	AESS_to_MPU_IRQ	IRQ sent from AESS to MCU. Refer to <a href="#">Chapter 12, ABE</a> .	-
hwobs_int_abe[22]	AESS_to_DSPSS_IRQ	IRQ sent from AESS to DSP. Refer to <a href="#">, Interrupt Requests, and Chapter 12, ABE</a> .	-
hwobs_int_abe[21]	Reserved	-	-
hwobs_int_abe[20]	GPT_WDT_PWM_INP	PWM received from the GPTIMER or watchdog (OR)	-
hwobs_int_abe[19]	AESS_DMAREQ_ALL	(logical OR will all dma req out)	High while outgoing DMA request from Audio Engine have not been acknowledged by the host.
hwobs_int_abe[18]	AESS_DMAREQ_PER	(logical OR with all dma req coming from the peripheral)	High when incoming dmarequest from Audio Engine are still to be served.
hwobs_int_abe[17]	AESS_IDLEPO	the PO_IDLE AESS output	High when the Audio Engine execute a wait until an activation of the PI_WAKEUP pin has been done.
hwobs_int_abe[16:0]	RESERVED	-	-

**18.4.11.5.6 USBOTGHS Subsystem Observable Signals**

One of the General Wakeup Control observability inputs can be mapped to the USBOTGHS "start of frame signal" - hsubotg\_sofpulse through setting the [CONTROL\\_CORE\\_CONF\\_DEBUG\\_SEL\\_TST\\_11\[3:0\]](#) MODE =0x1.

**18.4.11.5.7 CM2 Susbsystem Observable Signals**

The SYSCTRL\_GENERAL\_CORE observability inputs - hwobs\_int\_cm2(i) , (i=0..31) are mapped to the signals debugcm2(i), (i=0..31) coming out of the PRCM submodule -Clock Manager 2 (CM2).

There are local multiplexing controls at the CM2 level that reside in the CM2\_DEBUG\_CFG register. The CM2 observability output signals are driven on the debugcm2(0) through debugcm2(7) lines. A certain mux set is selected by programming the CM2\_DEBUG\_CFG[7:0] SEL0 bit field. The remaining debugcm2(8) through debugcm2(31) lines are reserved for future use. For more information about the CM2 observability source select field, see [Section 3.11.30.1, INTRCONN\\_SOCKET\\_CM2 Register Summary](#) in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 18-31](#) and [Table 18-32](#) describe CM2 observable signals specific to initiators and targets, respectively. [Table 18-33](#) describes other CM2 observable signals.

**Table 18-31. CM2 Observable Signals Specific to Initiators**

#### 18.4.11.5.8 CM1 Subsystem Observable Signals

The General Wakeup Control observability inputs - hwobs\_int\_cm1(i) , (i=0..31) are mapped to the signals debugcm1(i), (i=0..31) coming out of the PRCM submodule - Clock Manager 1 (CM1).

There are local multiplexing controls at the CM1 level that reside in the CM1\_DEBUG\_CFG register. The CM1 observability output signals are driven on the debugcm1(0) through debugcm1(7) lines. A certain mux set is selected by programming the CM1\_DEBUG\_CFG[6:0] SEL0 bit field. The remaining debugcm1(8) through debugcm1(31) lines are reserved for future use. For more information about the CM1 observability source select field, see [Section 3.11.22.1, INTRCONN\\_SOCKET\\_CM1 Register Summary](#) in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 18-34](#) and [Table 18-35](#) list CM1 observable signals specific to initiators and targets, respectively. [Table 18-36](#) lists other CM1 observable signals.

**Table 18-34. CM1 Observable Signals Specific to Initiators**

### 18.4.11.5.9 PRM Subsystem Observable Signals

The General Wakeup Control observability inputs - hwobs\_int\_prm(i), (i=0..31) are mapped to the signals debugprm(i), (i=0..31) coming out from the Power Reset Manager (PRM) submodule.

There are local multiplexing controls at the PRM level that reside in the PRM\_DEBUG\_CFG register. The PRM observability output signals are driven on the debugprm(0) through debugprm(7) lines. A certain mux set is selected by programming the PRM\_DEBUG\_CFG[6:0] SEL0 bit field. The remaining debugprm(8) through debugprm(31) lines are reserved for future use. For more information about the PRM observability source select field, see [Section 3.11.2.1, INTRCONN\\_SOCKET\\_PRM Register Summary](#) in [Chapter 3, Power, Reset, and Clock Management](#).

Table 18-37 through Table 18-40 list various PRM observable signals.

**Table 18-37. PRM - Observable Signals Specific to Targets**

hwobs_usbdpll_idle	dspDpllPhaseLock	dspDPLL phase lock check	-

### 18.4.12 Functional Register Description

#### 18.4.12.1 DSP Boot Register

This information is not available in the public domain.

#### 18.4.12.2 PBIASLITE Control Register

Table 18-48 describes the [CONTROL\\_PBIASLITE](#) register, which controls some settings of PBIAS LITE cells for the MMC I/O interface.

**Table 18-48. PBIAS Control Register**

<b>Physical Address</b>	<b>Register Name</b>	<b>Description</b>	<b>Access</b>
0x4A10 0600	<a href="#">CONTROL_PBIASLITE</a>	Control settings for PBIAS cell	R/W

For more information about the PBIAS cells, see [Section 18.4.9, Extended-Drain I/O and PBIAS Cell](#).

#### 18.4.12.3 Temperature Sensor Control Register

Table 18-49 describes the [CONTROL\\_TEMP\\_SENSOR](#) register, which controls the temperature sensor.

**Table 18-49. Temperature Sensor Register**

<b>Physical Address</b>	<b>Register Name</b>	<b>Description</b>	<b>Access</b>
0x4A00 232C	<a href="#">CONTROL_TEMP_SENSOR</a>	Temperature sensor control register	R/W

#### 18.4.12.4 CSI Receiver Control Register

To enable the physical layer of the camera receiver, the programmer manipulates the bits within the [CONTROL\\_CAMERA\\_RX](#) register.

**Table 18-50. CSI Receiver control Register**

<b>Physical Address</b>	<b>Register Name</b>	<b>Description</b>	<b>Access</b>
0x4A10 0608	<a href="#">CONTROL_CAMERA_RX</a>	Module dedicated configurations	R/W

### 18.4.12.5 Protection Status Registers

Table 18-51 lists the status registers.

**Table 18-51. Protection Status Registers**

Physical Address	Register Name	Description	Access
0x4A00 22D0	<a href="#">CONTROL_SEC_ERR_STATUS_FUNC</a>	Protection firewall error status register	Public (R)
0x4A00 22D4	<a href="#">CONTROL_SEC_ERR_STATUS_DEBUG</a>	Protection firewall error status register debug	Public (RW)

These registers do not depend on the device type.

The [CONTROL\\_PROT\\_ERR\\_STATUS\\_FUNC](#) can be read in public mode, but cannot be written. The [CONTROL\\_PROT\\_ERR\\_STATUS\\_DEBUG](#) register is both read and write accessible in GP devices.

These bits are cleared when the L3 and L4 firewall embedded error log registers are cleared. All bits in these registers reflect device internal events related to the device protection.

On a specific event (signal rising edge), the corresponding bit is set. On a rising edge, the input signal must stay high for at least two interface clocks periods to be recognized. Software must clear each bit after reviewing the events.

When a protection violation occurs, the following bits are set:

- In application mode
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_FUNC](#)[01] = L3RAM protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_FUNC](#)[02] = GPMC protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_FUNC](#)[03] = EMIF protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_FUNC](#)[04] = IVAHD protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_FUNC](#)[05] = Dual Cortex™-M3 protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_FUNC](#)[06] = SL2 protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_FUNC](#)[12] = C2C protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_FUNC](#)[13] = SGX protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_FUNC](#)[14] = DSS protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_FUNC](#)[15] = ISS protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_FUNC](#)[16] = L4\_PER protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_FUNC](#)[17] = L4\_CFG protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_FUNC](#)[18] = DEBUGSS protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_FUNC](#)[19] = L4 AudioBE protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_FUNC](#)[20] = C2C INIT protection violation
- In debug mode
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_DEBUG](#)[01] = L3RAM protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_DEBUG](#)[02] = GPMC protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_DEBUG](#)[03] = EMIF protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_DEBUG](#)[04] = IVAHD protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_DEBUG](#)[05] = Dual Cortex™-M3 protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_DEBUG](#)[06] = SL2 protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_DEBUG](#)[12] = C2C protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_DEBUG](#)[13] = SGX protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_DEBUG](#)[14] = DSS protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_DEBUG](#)[15] = ISS protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_DEBUG](#)[16] = L4\_PER protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_DEBUG](#)[17] = L4\_CFG protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_DEBUG](#)[18] = DEBUGSS protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_DEBUG](#)[19] = L4 AudioBE protection violation
  - [CONTROL\\_SEC\\_ERR\\_STATUS\\_DEBUG](#)[20] = C2C INIT protection violation

For more information about L4 firewall protection violation report mechanisms, see [Section 13.3.3.4.5, Firewall Error Logging in the Control Module](#). For more information about L3 firewall protection violation report mechanisms, see [Section 13.2.3.8, L3 Interconnect Error Analysis](#).

### 18.4.12.6 Signal Integrity Parameter Control Registers with Pad Group Assignment

#### 18.4.12.6.1 Signal Integrity Parameter Controls Overview

Most of the I/O cells associated to the device pads are configurable to deliver their carried signals to the targeted sink with maximum signal integrity. Configuration of these I/Os is done by pad groups assignment and not individually per pad.

The different I/O-specific requirements determine usage of different type of I/O cells for the device I/Os. Software controls associated with the signal integrity parameters are implemented at the SYSCTRL\_PADCONF\_CORE and SYSCTRL\_PADCONF\_WKUP level.

Following types of I/O cells associated with pad groups can be identified:

- LPDDR2 high-speed I/O cells with impedance(I), slew rate(SR) and weak driver (WD) settings
- High-speed I/O cells with far-end load (LB) settings
- Low -speed I/O cells with combined slew rate (SC) and load vs transmission line (TL) length -(LB) settings
- I/O cells with combined mode (MB) controls and load compensation (LB) settings
- 50-Ω output buffer I/O cells with mode (MB) controls and load compensation (LB) settings
- I/O cells with control (DS0) of the output driver impedance
- C2C I/O cells with LB0 control adjustable according to interface requirement / voltage mode
- I/O cells with pullup strength (PUSTRENGTH) and speed controls
- I2Cx I/O cells with pullup resistance vs capacitance load settings
- JTAG I/O cells with bus-holder enable control

The pad group assigned signal integrity controls are provided through the registers described in [Table 18-52](#).

**Table 18-52. Signal Integrity Parameter Control Registers**

Physical Address	Register Name	Description	Access
0x4A10 05A8	<a href="#">CONTROL_SMART1IO_PADCONF_0</a>	Signal integrity pad group assignment control register	R/W

#### 18.4.12.6.2 High-speed I/O Buffers with Impedance, Slew Rate and Weak Driver Settings

The LPDDR2IO (EMIF I/F) buffers are based on 1.2V- High-Speed Un-terminated Logic and require excellent driver impedance control to achieve optimal timing -EMI trade-offs. A specific type of device I/O cell with programmable features are used to meet this requirement. They support 1,2-V LPDDR2 operation with target speed of 400MHz. These IO cells are also provided with some additional features to support High Speed Inter -Chip (HSIC) interface.

Three types of software configurable I/O cells are integrated to support high-speed unterminated logic :

- Single-ended I/O cells
- Two-pad differential I/O cells
- Vref generation cell

Two-pad differential I/O cells are provided with differential receiver and complementary transmitter. They are used to support LPDDR2 clock (lpddr21\_ck,lpddr21\_nck, lpddr22\_ck, lpddr22\_nck) pads and LPDDR2 strobe ( lpddr21\_dqsi, lpddr21\_ndqsi, lpddr22\_dqsi, lpddr22\_ndqsi ,where i=0 to 3) pads.

A Vref-generation cell is integrated in the device to supply a Vref based receiver.

These I/O cells are integrated with the following controls located in the SYSCTRL\_PADCONF\_CORE module:

- ❑ Driver output impedance (I) controls

- SR controls
- WD controls to support HSIC interface and avoid floating pad
- Process-only impedance compensation using 5-bit binary coded schema separately for pullup p<1:5> and pulldown n<1:5> impedance
- Internal and external reference voltage source selection for the Vref generation cell
- Vref cell decoupling capacitor selection

**NOTE:** I/Os are non-failsafe, which means that voltage must never be applied at pad before the internal IO supply voltage VDDS is powered-up.

Programmable bits for impedance and SR control are provided when the I/Os are set to operate in driver mode (outputs).

The bits I[2:0] are used to program desired impedance value of the driver in the range 30  $\Omega$  to 80  $\Omega$ . [Table 18-53](#) describes the driver impedance settings.

**Table 18-53. Driver Impedance Output Settings**

I2	I1	I0	Drive Setting Name	Output Impedance (Ron)	Drive Strength  Ioh , Iol	Example: Ron	Example:  Ioh , Iol  for Rref=50 $\Omega$	Notes
0	0	0	Drv5	1.6*Rref	0.625*Iout	80 $\Omega$	5 mA	
0	0	1	Drv6	1.33*Rref	0.75*Iout	67 $\Omega$	6 mA	
0	1	0	Drv7	1.14*Rref	0.875*Iout	57 $\Omega$	7 mA	
0	1	1	Drv8	Rref	Iout	50 $\Omega$	8 mA	
1	0	0	Drv9	0.88*Rref	1.125*Iout	44 $\Omega$	9 mA	
1	0	1	Drv10	0.8*Rref	1.250*Iout	40 $\Omega$	10 mA	
1	1	0	Drv11	0.73*Rref	1.375*Iout	36 $\Omega$	11 mA	
1	1	1	Drv12	0.67*Rref	1.5*Iout	34 $\Omega$	11.6 mA	

**NOTE:**

- Reference output impedance is considered to be the production trim setting for Drv8 mode, which corresponds to Rout = 50  $\Omega$  / Iout = 8 mA.
- [Table 18-53](#) is valid for both pull-up and pull-down outputs.
- The drive strength column shows the equivalent output current Iout setting. Output currents IOH, IOL are measured at VOH, VOL of VDDS- 0.4 V and 0.4 V respectively.

To achieve optimal noise/ speed trade off, the slew rate of the output signal can also be programmed using the slew rate (turn-on time) control bits SR[1:0]. The SR settings shown in [Table 18-54](#) don't affect the driver DC drive -strength. They only control the driver turn -on time.

**Table 18-54. Driver Slew Rate Settings**

SR1	SR0	Turn-on time level	Turn on time for Drv8 setting (Value is the average for E-fuse setting)
0	0	Fastest	125 ps
0	1	Faster	500 ps
1	0	Fast	325 ps
1	1	Slow	750 ps

Weak pull-up, pull-down or a keeper on pad is enabled through bits wd0 and wd1. Weak pull-up, pull-down option is used to define the pad state (high or low) when no signal is driving the pad. The weak keeper option is used to maintain the previous output value, when nothing is driving the pad. [Table 18-55](#) describes the WD controls.

**NOTE:** The WD[1:0] bit field controls play role of the PULLTYPESELECT and PULLUDENABLE bits within the standard pad configuration registers, additionally providing the keeper function to the I/Os with the state WD=0b11. For LPDDR2 I/Os the WD controls do not apply during OFF-mode.

In contrast to the LPDDR2 I/Os, the usbb1\_hsic and usbb2\_hsic pads are additionally provided with bits to select weak pullup/pulldown and keeper function during OFF mode. For a given USBBx\_HSIC pad (where x=1,2) the associated bit to enable this option is OFFMODE\_WD\_ENABLE and the actual controls become OFFMODE\_WD[1:0] bits.

**Table 18-55. Weak Driver PUPD /Latch mode**

WD1	WD0	Operation
0	0	Pull logic disabled
0	1	Weak pullup enabled
1	0	Weak pulldown enabled
1	1	Weak keeper enabled

The E-fuse impedance compensation settings are exported upon power-on reset to 10 bits in the [CONTROL\\_EFUSE\\_2](#) register of the Device Control Module, as follows:

-[CONTROL\\_EFUSE\\_2\[23\]](#) LPDDR2\_PTV\_N1 through [CONTROL\\_EFUSE\\_2\[19\]](#) LPDDR2\_PTV\_N5 (pull-down impedance trimming)

-[CONTROL\\_EFUSE\\_2\[18\]](#) LPDDR2\_PTV\_P1 through [CONTROL\\_EFUSE\\_2\[14\]](#) LPDDR2\_PTV\_P5 (pull-up impedance trimming)

**CAUTION**

Do not override the E-fuse impedance compensation settings in the [CONTROL\\_EFUSE\\_2](#) register

The Voltage reference cell which is used with LPDDR2IO Vref based receiver has the following associated control bit fields in the [CONTROL\\_LPDDR2IO1\\_3](#) and [CONTROL\\_LPDDR2IO2\\_3](#) registers:

- Internal reference voltage drive selection through bits : VREF\_TAP0 and VREF\_TAP1 bits
- Selection of coupling capacitor between the internal reference node and power supply ports -( VDDS and VSS ) through bits: VREF\_CCAP0 and VREF\_CCAP1 bits

[Table 18-56](#) describes the possible options for internal reference voltage drive selection.

**Table 18-56. Internal reference configuration**

VREF_TAP1	VREF_TAP0	Description
0	0	Pad/bias2 Connected to internal reference VDDS/2, for 2- $\mu$ A current load
0	1	Pad/bias2 Connected to internal reference VDDS/2, for 4- $\mu$ A current load
1	0	Pad/bias2 Connected to internal reference VDDS/2, for 6- $\mu$ A current load
1	1	Pad/bias2 Connected to internal reference VDDS/2, for 8- $\mu$ A current load

In internal reference mode the Vref cell can also be used to supply reference voltage to other external devices.

Bits to enable / disable internal voltage reference for CA- and DQ- lines in manual and auto modes are available to user in registers [CONTROL\\_LPDDR2IO1\\_3](#) and [CONTROL\\_LPDDR2IO2\\_3](#) respectively. When auto and manual modes are enabled, manual controls take higher priority over the voltage reference.

**CAUTION**

While using the Vref cell in internal reference mode, nothing else should be driving the pad externally. Although the pad can be connected to supply Vref signal to other chips.

The possible options for coupling capacitor configuration is listed in [Table 18-57](#) :

**Table 18-57. Vref cell decoupling cap selection table**

VREF_CCAPO	VREF_CCAP1	Capacitor
0	0	No capacitor connected
0	1	Capacitor between internal reference node and VDD5
1	0	Capacitor between internal reference node and VSS
1	1	Capacitor between internal reference node and VDD5 as well as internal reference node and VSS

**18.4.12.6.3 Low Speed I/Os Combined Slew Rate vs TL Length and Load Settings**

[Table 18-58](#) provides the low-speed I/O cells SR control modes selectable through SC[1:0] bit field. These settings act like coarse settings for the signal performance behaviour of the low-speed I/Os. The SR settings determine three target maximal frequencies of I/Os operation at maximum load (see [Table 18-58](#).) The different slew control modes (0-2) requirements are described in [Table 18-59](#), [Table 18-61](#) and [Table 18-62](#).

[Table 18-60](#) lists the low-speed I/O cells - far-end capacitance load vs TL length settings selectable through bits LB[1] and LB[0], respectively. The four possible LB-settings described in [Table 18-60](#) are fully applicable and have maximum effect only in the case when slew control mode 0 is selected. These settings fine tune the signal performance. When SR control modes 1 and 2 are selected, then sensitivity to LB[1:0] setting is minimal, however LB[1:0] =11 achieves the best I/O performance.

**Table 18-58. Slew control mode (coarse) settings**

SC[1] bit	SC[0] bit	Slew Rate Control Mode	Maximum frequency achieved at maximum load
0	0	0	20MHz
0	1	1	60MHz
1	0	2	40MHz

**Table 18-59. Signal performance for slew control mode 0 - SC[1:0]=00**

Slew rate mode setting - SC[1:0]=00				
Parameter	Min	Max	Units	Comments
Transmission line Impedance	30	70	$\Omega$	-
Equivalent Load Range = ( Transmission line load + Far end load)	4	60	pF	Max load comes from dual transmission line
Transmission line(TL) length	2	20	cm	
Far end Load Range	2	10	pF	Assuming that characteristic impedance of TL is 50 $\Omega$

**Table 18-60. Load bit (fine) settings**

LB[1] (Far-end capacitance control)	LB[0] (TL- length control)	Effective TL lengt (cm)	Far-end capacitance (pF) (per TL)
0	0	2-20	1-10
0	1	20-40 (dual TL)	1-10
1	0	2-20	10-20
1	1	20-40 (dual TL)	10-20

**NOTE:** The LB modes in [Table 18-60](#) are fully applicable and have maximum effect only in the case of slew control mode 0 (SC[1:0]=00). For slew control modes 1 and 2, LB[1:0]=0b11 is recommended.

**Table 18-61. Signal performance for slew control mode 1 - SC[1:0]=01**

Slew rate mode setting - SC[1:0]=01				
Parameter	Min	Max	Units	Comments
Transmission line Impedance	30	70	$\Omega$	-
Equivalent Load Range = ( Transmission line load + Far-end load)	2	21	pF	This includes Far-end load and printed wiring board (PWB) trace
Transmission line(TL) length	1	6	cm	-
Far-end Load Range	1	15	pF	Assuming that characteristic impedance of TL is 50 $\Omega$

**NOTE:** When slew rate mode 1 is selected, it's recommended to set LB[1:0]=0b11 to achieve best signal performance.

**Table 18-62. Signal performance for slew control mode 2 - SC[1:0]=10**

Slew rate mode setting - SC[1:0]=10				
Parameter	Min	Max	Units	Comments
Transmission line impedance	30	70	$\Omega$	-
Equivalent Load Range = ( Transmission line load + Far end load)	7	33	pF	This includes Far-end load and printed wiring board (PWB) trace
Transmission line(TL) length	2	8	cm	
Far end Load Range	5	25	pF	assuming that characteristic impedance of TL is 50 $\Omega$

**NOTE:** When slew rate mode 2 is selected, it's recommended to set LB[1:0]=0b11 to achieve best signal performance.

#### 18.4.12.6.4 I/Os with Combined Mode and Load Settings

I/Os of this type has an output buffer with an internal PAD voltage SR control mechanism. Typical driver output impedance is 25  $\Omega$ . The corresponding I/O cell is controlled from two mode bits ( MB0 and MB1 ) and a dedicated bit ( LB0 ) for load compensation. [Table 18-63](#) describes the mode bit settings for each mode. The load bit programs the far end load for the I/O cell associated pads. [Table 18-63](#) also lists the load bit settings, and [Table 18-64](#) lists the I/O cell features in different modes.

**Table 18-63. Software controls for I/Os with combined Mode and Load settings**

Control Bits for I/Os with combined Mode vs Load settings			
MODE	MB1	MB0	LB0
MODE1	0	1	0
MODE2	1	0	0 (farend load < 15pf) 1 (farend load >= 15pf)
MODE3	1	1	0 (farend load < 4pf) 1 (farend load >= 4pf)
MODE4	1	1	(farend load < 4pf) 1 (farend load >= 4pf)

**Table 18-64. I/O cell Features in Different Modes**

Interface	Mode1	Mode2	Mode3	Mode4
	SDMMC/SPI	DMIC / GPIO / Asyn Ctrl signal	HSI	ULPI
Interface frequency (MHz)	48	4	200	60
Clload_max (pF)	10	35	5	5
Max TX.line length (cm)	10	20	5	6
Clload_min (pF)	2	5	3	2
Min TX.line length(cm)	2	2	2	2

**NOTE:** MODE4 is achieved by using the same mode setting as that of MODE3. The MODE4 design is limited by stringent delay requirement, even though the frequency is lower than MODE3.

A process-only compensation using 4-bit binary coded schema is used separately for pullup and pulldown output parameter variations. Only MODE2 doesn't use such compensation. The I/Os with combined mode and load controls ( 25- $\Omega$  output buffer ) share the same compensation settings with the I/Os with driver output impedance (DS) settings as well as with the C2CI/O buffers. They are exported from E-fuse upon power-on reset to the following bits in the [CONTROL\\_EFUSE\\_2](#) register:

- [CONTROL\\_EFUSE\\_2](#)[31] EFUSE\_SMART2TEST\_P0 through [CONTROL\\_EFUSE\\_2](#)[28] EFUSE\_SMART2TEST\_P3 (pullup output parameters trimming)
- [CONTROL\\_EFUSE\\_2](#)[27] EFUSE\_SMART2TEST\_N0 through [CONTROL\\_EFUSE\\_2](#)[24] EFUSE\_SMART2TEST\_N3 (pulldown output parameters trimming)

#### CAUTION

Do not override the SMART2TEST\_P / SMART2TEST\_N - E-fuse compensation settings in the [CONTROL\\_EFUSE\\_2](#) register

**18.4.12.6.5 50-Ω Output Buffer I/Os with Combined Mode and Load Settings**

I/Os of this type has an output buffer with an internal PAD voltage slew rate control mechanism. Driver output impedance is typically 50 Ω. The corresponding I/O cell is controlled from two mode bits MB0 and MB1 and a dedicated bit LB0 for load compensation. They are located within a number of the device signal integrity control registers - CONTROL\_SMART3IO\_PADCONF\_x (x=0,1,2), CONTROL\_SMART3IO\_PADCONF\_3, CONTROL\_SMART3NOPMIO\_PADCONF\_0, CONTROL\_SMART3NOPMIO\_PADCONF\_1 registers. MODE1 for this type of I/O cells meets different specific requirements than MODE1 for buffers described in Section 18.4.12.6.4. The recommended mode and load bit settings are listed in table Table 18-65

**Table 18-65. Software controls for 50-Ω output buffer I/O cells with combined Mode and Load settings**

Control Bits for I/Os with 50-Ω output buffer and combined Mode vs Load settings				
MODE	MB1	MB0	LB0	
MODE1	1	1	1	
MODE2	0	1	0	
MODE3	1	0	1	
MODE4	1	0	0	

The different mode features are described in Table 18-66.

**Table 18-66. Different Mode features**

Interface	Mode1	Mode2	Mode3	Mode4
Interface frequency (MHz)	60	48	24	25
Cload_max (pF)	5	5	20	11
Cload_min (pF)	2	2	16	2

A process-only compensation using 4-bit binary coded schema is used separately for pull-up and pull-down output parameter variations. Only MODE1 and MODE2 make use of Efuse process-only compensation to reduce spread in timing parameters. The I/Os with 50-Ω output buffer and combined mode and load controls share the same compensation settings with the I/Os with driver output impedance (DS) settings as well as with the C2CI/O buffers. They are exported from E-fuse upon power-on reset to the following bits in the CONTROL\_EFUSE\_2 register:

- CONTROL\_EFUSE\_2[31] EFUSE\_SMART2TEST\_P0 through CONTROL\_EFUSE\_2[28] EFUSE\_SMART2TEST\_P3 (pull-up output parameters trimming)
- CONTROL\_EFUSE\_2[27] EFUSE\_SMART2TEST\_N0 through CONTROL\_EFUSE\_2[24] EFUSE\_SMART2TEST\_N3 (pull-down output parameters trimming)

**CAUTION**

Do not override the SMART2TEST\_P / SMART2TEST\_N - E-fuse compensation settings in the CONTROL\_EFUSE\_2 register

**18.4.12.6.6 I/O cells with Configurable Output Driver Impedance**

This type of I/O cells has an output buffer with an internal PAD voltage slew rate control mechanism. It operates in 25 Ω or 50 Ω impedance mode depending on the drive strength bit - DS0 setting. The drive strength control logic is explained in Table 18-67. The performance characteristics at different power modes 1.2/1.8 V are shown in Table 18-68. These controls are located within the CONTROL\_SMART2IO\_PADCONF\_2 register.

**Table 18-67. Driver Impedance Control**

MODE	DS0	Impedance
MODE1	1	25 Ω
MODE2	0	50 Ω

**Table 18-68. I/O cell performance for different impedances**

Control Bits for I/Os with configurable driver output impedance			
DS0 setting	TL impedance ( $\Omega$ )	Load (pF)	Max. Freq. (MHz)
0	40-60	2-5	75
1	30-45	2-5	100

A process-only compensation using 4-bit binary coded schema is used separately for pull-up and pull-down output parameter variations. Only MODE1 and MODE2 make use of Efuse process-only compensation to reduce spread in timing parameters. The I/Os with driver impedance (DS) control share the same compensation settings with the I/Os with combined mode and load controls (both with 25- and 50- $\Omega$  output ) as well as with the C2C/I/O buffers. They are exported from E-fuse upon power-on reset to the following bits in the [CONTROL\\_EFUSE\\_2](#) register:

-[CONTROL\\_EFUSE\\_2\[31\]](#) EFUSE\_SMART2TEST\_P0 through [CONTROL\\_EFUSE\\_2\[28\]](#) EFUSE\_SMART2TEST\_P3 (pull-up output parameters trimming)

-[CONTROL\\_EFUSE\\_2\[27\]](#) EFUSE\_SMART2TEST\_N0 through [CONTROL\\_EFUSE\\_2\[24\]](#) EFUSE\_SMART2TEST\_N3 (pull-down output parameters trimming)

#### 18.4.12.6.7 C2C/I/O cells with load setting adjustable according to interface requirement / voltage mode

This IO cell can be configured to be used in different interfaces, like C2C, GPMC and SDMMC2 using a single-bit (LB0) selection. Like LPDDR2IO this IO cell is provided with selectable Lvcmos and Vref based receiver option. A vref pad is provided to supply reference voltage to the receiver in the 1.2V mode. To save power at lower frequency operation, lvcmos receiver can be selected, and two bits , for each of the two C2C pad groups are used to manually enable/disable the LVC MOS receiver - CMOSEN\_C2C\_FRM\_CTRL in the [CONTROL\\_C2CIO\\_PADCONF\\_0](#) register. Tables [Table 18-69](#) through [Table 18-71](#) explain the logic of the mode selection bit for use in different interfaces .

**Table 18-69. I/O cell performance for C2C I/F at 1.2/1.8 V**

Control Bits of the C2C I/O cell in C2C application						
Interface /Voltage Mode	LB0 bit setting	Interface summary	Fmax	TL impedance	TX Far-end load end	TL length
C2C 1.2 V	1	Interface with LPDDR1 modem. Modem multiplex its own LPDDR1 I/F with its own C2C I/F	200 MHz (400Mbps)	40-55 $\Omega$	2-4 pF	2 cm
C2C 1.8 V	1	Interface with LPDDR2 modem. Modem multiplex its own LPDDR2 I/F with its own C2C I/F	200 MHz (400 Mbps)	40-55 $\Omega$	2-4 pF	2 cm

**Table 18-70. I/O cell performance for GPMC I/F at 1.2/1.8 V**

Control Bits of the C2C I/O cell in GPMC application						
Interface /Voltage Mode	LB0 bit setting	Interface summary	Fmax	TL impedance	TX Far-end load end	TL length
GPMC 1.2 V	0	100MHz I/F [Read] 83MHz Interface [Write]	100 MHz	30-50 $\Omega$	5-10 pF	4 cm
GPMC 1.8 V	1	100MHz I/F [Read] 83MHz Interface [Write]	100 MHz	30-50 $\Omega$	5-10 pF	4 cm

**Table 18-71. I/O cell performance for SDMMC2 I/F at 1.2/1.8 V**

Control Bits of the C2C I/O cell in GPMC application						
Interface /Voltage Mode	LB0 bit setting	Interface summary	Fmax	TL impedance	TX Far-end load end	TL length
SDMMC2 1.2 V	0	48 MHz I/F	48 MHz SDR 96 MHz DDR	30-55 $\Omega$	2-5 pF	2-5 cm
SDMMC2 1.8 V	0	48 MHz I/F	48 MHz SDR 96 MHz DDR	30-55 $\Omega$	2-5 pF	2-5 cm

The Voltage reference cell which is used with C2CIO Vref based receiver has the following associated control bit fields in the [CONTROL\\_C2CIO\\_PADCONF\\_0](#) register:

- Selection of coupling capacitor between the internal reference node and power supply ports - VDDS and VSS through bit field: C2C\_VREF\_CCAP.

In the internal reference mode the Vref cell can also be used to supply reference voltage to other external devices. At Vdds=1.8V mode, the Internal reference generator will be shut off and internal reference node will be connected to zero.

Bits to enable / disable the internal voltage reference in manual and auto modes are available to user in registers [CONTROL\\_C2CIO\\_PADCONF\\_0](#) respectively. When auto and manual modes are enabled, manual controls take higher priority over the voltage reference.

#### CAUTION

While using the Vref cell in internal reference mode, nothing else should be driving the pad externally. Although the pad can be connected to supply Vref signal to other chips.

The possible options for coupling capacitor configuration is listed in [Table 18-72](#) :

**Table 18-72. Vref cell decoupling cap selection table**

VREF_CCAP0	VREF_CCAP1	Capacitor
0	0	No capacitor connected
0	1	Capacitor between internal reference node and VDDS
1	0	Capacitor between internal reference node and VSS
1	1	Capacitor between internal reference node and VDDS as well as internal reference node and VSS

A process-only compensation using 4-bit binary coded schema is used separately for pull-up and pull-down output parameter variations. The C2CI/O buffers share the same compensation settings with the I/Os with combined mode and load controls (both with 25- and 50- $\Omega$  output ) and I/Os with driver output impedance (DS) settings. They are exported from E-fuse upon power-on reset to the following bits in the [CONTROL\\_EFUSE\\_2](#) register:

- [CONTROL\\_EFUSE\\_2](#)[31] EFUSE\_SMART2TEST\_P0 through [CONTROL\\_EFUSE\\_2](#)[28] EFUSE\_SMART2TEST\_P3 (pull-up output parameters trimming)
- [CONTROL\\_EFUSE\\_2](#)[27] EFUSE\_SMART2TEST\_N0 through [CONTROL\\_EFUSE\\_2](#)[24] EFUSE\_SMART2TEST\_N3 (pull-down output parameters trimming)

#### 18.4.12.6.8 SDMMC1 Pull-up Strength Control

The SDMMC1\_PUSTRENGTH\_GRPi (where i=1 to 3) control bits are added to program the pullup strength for the MMC/SD/SDIO1 I/Os group. [Table 18-73](#) lists the supported pullup resistance ranges.

**Table 18-73. SDMMC1 Pullup Strength Controls**

Pustrength controls	
SDMMC1_PUSTRENGTH_GRPi = 0b0	SDMMC1_PUSTRENGTH_GRPi=0b1
Pullup with 50-100 kΩ strength selected	Pullup with 10-50 kΩ strength selected

#### 18.4.12.6.9 I2Cx I/Os Group Pullupresx Controls and Load Range Settings

Table 18-74 provides examples of pull-up resistance vs load range I2Cx I/O signal integrity control capabilities. Three possible operation modes of the I2C associated I/O cells are shown: non-I2C, Full speed (FS) and High speed (HS) modes (see Section 23.1, *Multimaster Highspeed I2C controller*). Non-I2C mode means that the MuxMode field in I2Cx dedicated PADCONFS is set to select signals different than I2C signals, see Section 18.4.8.3.

**Table 18-74. Example I2Cx Pullupresx vs. I2C LB Parameter Settings in Different Modes**

Non I2C mode	FS I2C bus mode	HS I2C p2p mode
nmode=1 hsmode=0 pullupresx=1 lb[1:0]=00	nmode=0 hsmode=0 pullupresx=1 lb[1:0]=00 400kHz, external PU	nmode=0 hsmode=1 pullupresx=0 lb[1:0]=00 3.4 MHz, cap. load 5-12 pF

The I2Cx buffer contains internal pull-up resistors for both Fast and High-Speed modes meeting I2C rise time specifications for loads up to 80 pF in HS mode and 150 pF in FAST mode. LB[1:0] signals can be used to select appropriate pullup resistor for a given load range. Table 18-75 lists the configuration options.

Active high GLFENB[0] bit is implemented for I2C receivers to enable glitch-free operation.

**Table 18-75. Internal Pullup Resistor in Fast/HS Mode**

LB1	LB0	Load Range HS Mode (pF)	Nominal Resistance in HS Mode (Ω)	Load Range Fast Mode (pF)	Nominal Resistance in Fast Mode (Ω)
0	0	5-12	1.66K	5-15	4.5K
0	1	12-25	920	15-50	2.1K
1	0	25-50	500	50-150	860
1	1	50-80	300	-	-

If a suitable external pullup resistor is used, I<sup>2</sup>C I/Os can meet I<sup>2</sup>C rise/fall time specifications in 1.2 / 1.8V mode under all modes up to 400 pF. The type of the pullup resistor (external or internal) for a certain I2Cx I/O group (x=1 to 4) is selected through the I2Cx\_SCL\_PULLUPRESX and I2Cx\_SDA\_PULLUPRESX bits. Internal pullups are activated when I2Cx\_SCL\_PULLUPRESX / I2Cx\_SDA\_PULLUPRESX =0b0. I2C functionality is not ensured if the weak internal pullup or pulldown (the 100 μA nominal PU-PD) is activated on any of the I/Os connected to the bus.

#### 18.4.12.6.10 Device Interfaces Signal Group Controls Mapping

Table 18-76 through Table 18-103 describes the mapping of the different signal integrity control bit fields in the different signal integrity control register described in the Table 18-52.

**NOTE:** The same I/O cell and I/O cell controls assigned to pad signal available when Muxmode = 0 are shared between signals available on the same pad when Muxmode is selected different than 0. For more information, see Section 18.4.8.3, *Pad Multiplexing Register Fields*.

<a href="#">CONTROL_SMART2IO_PADCONF_2</a> [29] DPM_DR3_DS;	dpm_emu18; dpm_emu19	I/O cell with single-bit drive strength (DS) control for driver output impedance (See <a href="#">Section 18.4.12.6.6</a> for more information)

#### 18.4.12.7 Dual Voltage-Supplied Peripheral Controls

Some of the peripheral I/Os have the option to be supplied with a 1,2-V or 1,8-V power supply (VDDS through chip external pads). The power supply level to the dual voltage I/Os of different peripherals is configurable through bit fields in register [CONTROL\\_CORE\\_PADCONF\\_MODE](#) in the CORE domain - (EMIF, GPMC, C2C, CAMERA, SDMMC2 I/Os) and [CONTROL\\_WKUP\\_PADCONF\\_MODE](#) in the WKUP domain - (EMIF and FREF generator).

## 18.5 Control Module Programming Guide

### 18.5.1 Control Module Low-Level Programming Models

This section covers the low-level programming sequences for configuration and use of the control module.

#### 18.5.1.1 Global Initialization

##### 18.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the control module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the environment and integration of the control module. See [Section 18.2](#), *Control Module Environment* and [Section 18.3](#), *Control Module Integration* for further information.

**Table 18-104. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	The two clocks, CFG_L4_ICLK and WKUP_L4_ICLK2 coming from PRCM are not software-controlled by PRCM. See <a href="#">Section 3.6.3.2.4</a> , <i>CM2 Clock Generator</i> and <a href="#">Section 3.6.3.1</a> , <i>PRM Clock Source</i> in <a href="#">Chapter 3</a> , <i>Power, Reset, and Clock Management</i> for more information about the two clocks.
L4 interconnect	For information about L4-CFG interconnect configuration, see <a href="#">Section 13.3</a> , <i>L4 Interconnects</i> in <a href="#">Chapter 13</a> , <i>Interconnects</i> .

##### 18.5.1.1.2 Control Module Global Initialization

###### 18.5.1.1.2.1 Software Reset

The Control Module is not sensitive to a software reset.

###### 18.5.1.1.2.2 Clock Gating Configuraton

As described in [Section 18.4.2](#), *Control Module Clock Configuration*, the programmer can choose clock-gating strategy individually for each of the four Control Module instances. [Table 18-105](#) explains the necessary steps.

**Table 18-105. Configure Clock Gating for Different Control Module Instances**

Step	Register/ bit field / Programming Model	Value
1. Set clock gating for SYCTRL_PADCONF_CORE	<a href="#">CONTROL_PADCONF_CORE_SYSCONFIG</a> [3:2]	0x-
2. Set clock gating for SYCTRL_PADCONF_WKUP	<a href="#">CONTROL_PADCONF_WKUP_SYSCONFIG</a> [3:2]	0x-
3. Set clock gating for SYCTRL_GENERAL_CORE	<a href="#">CONTROL_GEN_CORE_SYSCONFIG</a> [3:2]	0x-
4. Set clock gating for SYCTRL_GENERAL_WKUP	<a href="#">CONTROL_GEN_WKUP_SYSCONFIG</a> [3:2]	0x-

#### 18.5.1.2 Operational Modes Configuration

##### 18.5.1.2.1 Video Driver Configuration

This section gives information about all modules and features in the high-tier device.

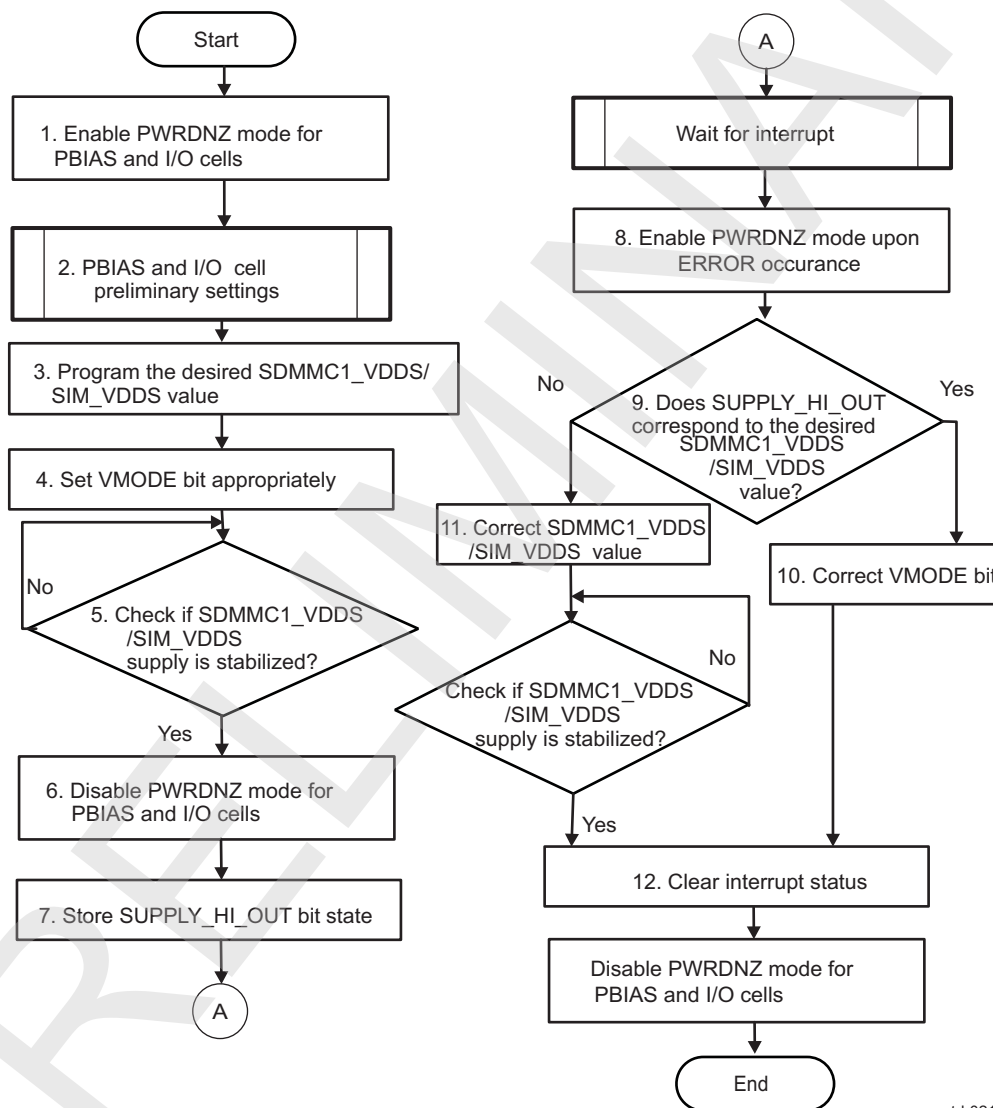

For more details on video DAC, see [Section 10.6](#), *Video Encoder*.

**Table 18-106. Control Module AVDAC Configuration**

Step	Register/ bit field / Programming Model	Value
1.Video buffer is bypassed / not bypassed	CONTROL_AVDAC[30] AVDAC_TVOUTBYPASS	0b-
2.Enable/disable ac coupling for TV output	CONTROL_AVDAC[31] AVDAC_ACEN	0b-

### 18.5.1.2.2 Extended-Drain I/Os and PBIAS Cells Programming Guide

This section describes the programming flow to go from 3.0 V to 1.8 V, and vice versa when operating with the extended-drain I/Os and PBIAS cells.

**Figure 18-18. Configuring PBIAS Cell to Operate in Different Modes, Interrupt Method**

sysctrl-021

**Table 18-107. Register Settings for Configuring the MMC1\_PBIAS and MMC1 I/O Cells**

Procedure Name	Description	Register Settings
1. Enable PWRDNZ mode for MMC1_PBIAS cell , and MMC/SD/SDIO1 I/O cell.	Software must keep MMC1_PBIAS cell and MMC1_IO cell PWRDNZ signals Software must keep MMC1_PBIAS cell and MMC1_IO cell PWRDNZ signals LOW whenever SDMMC1_VDDS is ramping up/down. or changing .This is for cell protection purposes.	1. Set <a href="#">CONTROL_PBIASLITE</a> [22] MMC1_PBIASLITE_PWRDNZ = 0b0. 2. Set <a href="#">CONTROL_PBIASLITE</a> [26] MMC1_PWRDNZ = 0b0.
2. Preliminary MMC1_PBIAS and MMC1 IO cell settings	Enable MMC1_PBIAS cell output and MMC1_PBIAS error associated interrupt Select desired I/Os within the MMC1 I/O cell and set appropriately corresponding pad configuration fields Set the group speed and pull-up strength controls for the MMC/SD/SDIO1 pads.	1. Set <a href="#">CONTROL_PBIASLITE</a> [25]MMC1_PBIASLITE_HIZ_MODE = 0b0. 2. See <a href="#">Chapter 17, Interrupt Controller</a> , for more information about setting MA_IRQ_75 line associated interrupt request PBIAS_IRQ. 3. For I/O multiplexing and pad configuration settings, see <a href="#">Section 18.5.1.2.5, Pad Configuration Programming Points</a> . 4. Set the speed control bits for the MMC1 I/O cell pads: <ul style="list-style-type: none"> <li>• <a href="#">CONTROL_MMC1</a>[27] SDMMC1_DR0_SPEEDCTRL = 0b-</li> <li>• <a href="#">CONTROL_MMC1</a>[26] SDMMC1_DR1_SPEEDCTRL = 0b-</li> <li>• <a href="#">CONTROL_MMC1</a>[28] SDMMC1_DR2_SPEEDCTRL = 0b-</li> </ul> 5. Set the pullup strength control bits for the MMC1 I/O cell pad groups: <ul style="list-style-type: none"> <li>• <a href="#">CONTROL_MMC1</a>[31] SDMMC1_PUSTRENGTH_GRP0=0b-</li> <li>• <a href="#">CONTROL_MMC1</a>[30] SDMMC1_PUSTRENGTH_GRP1=0b-</li> <li>• <a href="#">CONTROL_MMC1</a>[29] SDMMC1_PUSTRENGTH_GRP2=0b-</li> <li>• <a href="#">CONTROL_MMC1</a>[28] SDMMC1_PUSTRENGTH_GRP3=0b-</li> </ul>
3. Program the desired SDMMC1_VDDS voltage for MMC/SD/SDIO1 I/Os.	Program external power supply IC to generate appropriate SDMMC1_VDDS voltage:(3-V / 1.8-V).	See <a href="#">Section 23.1, Multimaster Highspeed I2C</a> , for more information on I <sup>2</sup> C interface operation.
4. Set VMODE bit appropriately.	PBIAS voltage generation is based on VMODE value, set according to to externally applied SDMMC1_VDDS voltage.	Set <a href="#">CONTROL_PBIASLITE</a> [21] MMC1_PBIASLITE_VMODE = 0b- <sup>(1)</sup>
5. Check if SDMMC1_VDDS supply is stabilized?	Check the state of the externally generated SDMMC1_VDDS voltage, which is provided through communication between the device and external power supply chip over I <sup>2</sup> C interface.	See <a href="#">Section 23.1, Multimaster Highspeed I2C</a> , for more information on I <sup>2</sup> C interface settings.
6. Disable PWRDNZ (power down) mode for MMC1_PBIAS and associated extended-drain MMC1 I/O cell.	This starts up the MMC1_PBIAS cell work to generate the PBIAS voltage.	1. Set <a href="#">CONTROL_PBIASLITE</a> [22] MMC1_PBIASLITE_PWRDNZ = 0b1. 2. Set <a href="#">CONTROL_PBIASLITE</a> [26] MMC1_PWRDNZ = 0b1.
7. Store SUPPLY_HI_OUT bit state.	Done as a preliminary step for error handling analysis. (Whenever PWRDNZ = 0b0 , SUPPLY_HI_OUT is unconditionally set to 0b0.)	Store <a href="#">CONTROL_PBIASLITE</a> [24] MMC1_PBIASLITE_SUPPLY_HI_OUT bit in memory.
8.Enable PWRDNZ mode upon error occurrence.	It is recommended that all the I/Os are powered down (PWRDNZ = 0) as soon as VMODE_ERROR is high.	1. Set <a href="#">CONTROL_PBIASLITE</a> [26] MMC1_PWRDNZ = 0b0 . 2. Set <a href="#">CONTROL_PBIASLITE</a> [22]MMC1_PBIASLITE_PWRDNZ = 0b0.
9. Does SUPPLY_HI_OUT correspond to the desired SDMMC1_VDDS?	Test if error comes from incorrectly set SDMMC1_VDDS value or incorrectly set VMODE bit.	Check the stored in memory SUPPLY_HI_OUT bit.
10. Correct VMODE bit	If SUPPLY_HI_OUT level corresponds to desired SDMMC1_VDDS value, then correct the value of the VMODE bit.	Modify value of <a href="#">CONTROL_PBIASLITE</a> [21] MMC1_PBIASLITE_VMODE.
11. Correct SDMMC1_VDDS value.	If SUPPLY_HI_OUT is different from expected , correct and set SDMMC1_VDDS value over I <sup>2</sup> C again	See <a href="#">Section 23.1, Multimaster Highspeed I2C</a> , for more information on I <sup>2</sup> C interface settings.

<sup>(1)</sup> Should be set HIGH when external MMC1\_VDDS source programmed to be 3V, or LOW when external MMC1\_VDDS source programmed to be 1.8 V. Reset default value corresponds to 3-V .

**Table 18-107. Register Settings for Configuring the MMC1\_PBIAS and MMC1 I/O Cells (continued)**

Procedure Name	Description	Register Settings
12. Clear Interrupt status.	Clear the IRQ_MA_75 interrupt status flag.	See <a href="#">Chapter 17, Interrupt Controller</a> , for more information about setting MA_IRQ_75 line associated interrupt request PBIAS_IRQ.

**Table 18-108. Register Settings for Configuring the PBIAS1 Cell, USBC1\_ICUSB and gpio\_wk0gpio\_wk2 Associated I/O Cells**

Procedure Name	Description	Register Settings
1. Enable PWRDNZ (power down) mode for PBIAS1 cell ,USBC1_ICUSB I/O cell and gpio_wk0-gpio_wk2 associated I/O cell.	Software must keep PBIAS1 cell and the associated USBC1_ICUSB and gpio_wk0-gpio_wk2 I/O cells PWRDNZ signals LOW whenever SIM_VDDS is ramping up/down or changing. This is for cell protection purposes.	<ol style="list-style-type: none"> <li>1. Set <a href="#">CONTROL_PBIASLITE</a>[28] PBIASLITE1_PWRDNZ = 0b0.</li> <li>2. Set <a href="#">CONTROL_PBIASLITE</a>[20] USBC1_ICUSB_PWRDNZ = 0b0.</li> <li>3. Set <a href="#">CONTROL_GPIOWK</a>[28] GPIOWK_IO_PWRDNZ = 0b0.</li> </ol>
2. Preliminary MMC1_PBIAS and MMC1 IO cell settings	Enable MMC1_PBIAS cell output and MMC1_PBIAS error associated interrupt Select desired I/Os within the USBC1_ICUSB and GPIOWK I/O cells and set appropriately their corresponding pad configuration fields Set the speed and pull-down controls for the pads (if applicable).	<ol style="list-style-type: none"> <li>1. Set <a href="#">CONTROL_PBIASLITE</a>[31] PBIASLITE1_HIZ_MODE = 0b0.</li> <li>2. See <a href="#">Chapter 17, Interrupt Controller</a>, for more information about setting MA_IRQ_75 line associated interrupt request PBIAS_IRQ.</li> <li>3. For I/O multiplexing and pad configuration settings, see <a href="#">Section 18.5.1.2.5, Pad Configuration Programming Points</a>.</li> <li>4. Set the speed control bits for USBC1_ICUSB I/O cell pads <a href="#">CONTROL_MMC1</a>[24] USBC1_DR0_SPEEDCTRL = 0b- (No speedctrl available for GPIOWK associated I/O cell).</li> <li>5. Disable strong pulldowns on the gpio_wk1 and gpio_wk2 pads available by default after reset: <ul style="list-style-type: none"> <li>• <a href="#">CONTROL_GPIOWK</a>[31] PAD_GPIO_WK1_LOW = 0b0</li> <li>• <a href="#">CONTROL_GPIOWK</a>[29] PAD_GPIO_WK2_LOW = 0b0</li> </ul> </li> </ol>
3. Program the desired SIM_VDDS voltage for the USBC1_ICUSB / gpio_wk0-gpio_wk2 or( hw_dbg1 - hw_dbg3 in WKUP domain) I/Os .	Program external power supply IC to generate appropriate SIM_VDDS voltage:(3-V/1.8-V)	See <a href="#">Section 23.1, Multimaster Highspeed I2C</a> , for more information on I <sup>2</sup> C interface operation.
4. Set VMODE bit appropriately.	PBIAS voltage generation is based on VMODE value, set according to to externally applied SIM_VDDS voltage.	Set <a href="#">CONTROL_PBIASLITE</a> [27] PBIASLITE1_VMODE = 0b-. <sup>(1)</sup>
5. Check if SIM_VDDS supply is stabilized?	Check the state of the externally generated SIM_VDDS voltage. This is provided through communication between device and companion power supply chip over I2C interface.	See <a href="#">Section 23.1, Multimaster Highspeed I2C</a> , for more information on I <sup>2</sup> C interface settings.
6. Disable PWRDNZ (power down) mode for PBIAS1 cell and its associated extended-drain USBC1_ICUSB and gpio_wk0-gpio_wk2 I/O cells.	This starts up the the PBIAS1 cell work to generate the PBIAS voltage.	<ol style="list-style-type: none"> <li>1. Set <a href="#">CONTROL_PBIASLITE</a>[28] PBIASLITE1_PWRDNZ = 0b1.</li> <li>2. Set <a href="#">CONTROL_PBIASLITE</a>[20 ] USBC1_ICUSB_PWRDNZ = 0b1.</li> <li>3. Set <a href="#">CONTROL_GPIOWK</a>[28] GPIOWK_IO_PWRDNZ = 0b1.</li> </ol>
7. Store SUPPLY_HI_OUT bit state.	Done as a preliminary step for error handling analysis. (Whenever PWRDNZ = 0b0 , SUPPLY_HI_OUT is unconditionally set to 0b0.)	Store <a href="#">CONTROL_PBIASLITE</a> [30] PBIASLITE1_SUPPLY_HI_OUT bit in memory.
8.Enable PWRDNZ mode upon error occurrence.	It is recommended that all the I/Os are powered down (PWRDNZ = 0) as soon as VMODE_ERROR is high.	<ol style="list-style-type: none"> <li>1. Set <a href="#">CONTROL_PBIASLITE</a>[28] PBIASLITE1_PWRDNZ = 0b0.</li> <li>2. Set <a href="#">CONTROL_PBIASLITE</a>[20] USBC1_ICUSB_PWRDNZ = 0b0.</li> <li>3. Set <a href="#">CONTROL_GPIOWK</a>[28] GPIOWK_IO_PWRDNZ = 0b0.</li> </ol>

<sup>(1)</sup> Should be set HIGH when external SIM\_VDDS source programmed to be 3V, or LOW when external SIM\_VDDS source programmed to be 1.8 V. Reset default value corresponds to 3-V . Reset default value corresponds to 3-V .

**Table 18-108. Register Settings for Configuring the PBIAS1 Cell, USBC1\_ICUSB and gpio\_wk0gpio\_wk2 Associated I/O Cells (continued)**

Procedure Name	Description	Register Settings
9. Does SUPPLY_HI_OUT correspond to the desired SIM_VDDS level?	Test if error comes from incorrectly set SIM_VDDS value or incorrectly set VMODE bit.	Check the stored in memory SUPPLY_HI_OUT bit.
10. Correct VMODE bit.	If SUPPLY_HI_OUT level corresponds to desired SIM_VDDS value, then correct the value of VMODE bit.	Modify value of <a href="#">CONTROL_PBIASLITE[27]</a> PBIASLITE1_VMODE.
11. Correct SIM_VDDS value.	If SUPPLY_HI_OUT is different than expected, correct and set SIM_VDDS value over I <sup>2</sup> C again.	See <a href="#">Section 23.1, Multimaster Highspeed I2C</a> , for more information on I <sup>2</sup> C interface settings.
12. Clear Interrupt status.	Clear the IRQ_MA_75 interrupt status flag.	See <a href="#">Chapter 17, Interrupt Controller</a> , for more information about setting MA_IRQ_75 line associated interrupt request PBIAS_IRQ.

### 18.5.1.2.3 Hardware Observability Settings

This section describes the procedures to control hardware observability features of the device. To configure hardware observability feature, the programmer must perform the steps listed in [Table 18-109](#).

**Table 18-109. Configure Hardware Observability Features**

Step	Register/Bit Field/Programming Model	Value
1. Select hwobs(0) signal frequency divider value	<a href="#">CONTROL_HWOBS_CONTROL[7:3]</a> HWOBS_CLKDIV_SEL	0x- <sup>(1)</sup>
2. Enable/disable hwobs gating and alternatively set all hwobs ports to either 0 or 1.	1. <a href="#">CONTROL_HWOBS_CONTROL[2]</a> HWOBS_ALL_ZERO_MODE 2. <a href="#">CONTROL_HWOBS_CONTROL[1]</a> HWOBS_ALL_ONE_MODE	0x- <sup>(2)</sup>
3. Enable/disable hwobs port gating only for signals coming from IPs identified in the MACRO group.	<a href="#">CONTROL_HWOBS_CONTROL[0]</a> HWOBS_MACRO_ENABLE	0x- <sup>(3)</sup>
4. Associate a certain hwobs channel to either CORE or WKUP power domain	Configure each bit from the bit field <a href="#">CONTROL_DEBOBS_FINAL_MUX_SEL[31:0]</a> SELECT appropriately for its corresponding hw_dbg channel	0x-
5. Choose the source of a signal or signal view channel in the CORE power domain	Configure each of the bit fields <a href="#">CONTROL_CORE_CONF_DEBUG_SEL_TST_0[3:0]</a> MODE through <a href="#">CONTROL_CORE_CONF_DEBUG_SEL_TST_31[3:0]</a> MODE appropriately for its corresponding hw_dbg channel	0x-
6. Choose the source of a signal within the WKUP power domain	Configure each bit <a href="#">CONTROL_WKUP_CONF_DEBUG_SEL_TST_i [0]</a> MODE, (where i=0 to 31) appropriately for its corresponding hw_dbg channel i (where i=0 to 31)	0x-
7. Choose to associate a certain DPLL signal to a given DPLL signal view channel	1. <a href="#">CONTROL_CONF_DPLL_FREQLOCK_SEL[2:0]</a> MULT 2. <a href="#">CONTROL_CONF_DPLL_TINITZ_SEL[2:0]</a> MULT 3. <a href="#">CONTROL_CONF_DPLL_PHASELOCK_SEL[2:0]</a> MULT 4. <a href="#">CONTROL_CONF_DPLL_TENABLE_SEL[2:0]</a> MULT 5. <a href="#">CONTROL_CONF_DPLL_TENABLEDIV_SEL[2:0]</a> MULT 6. <a href="#">CONTROL_CONF_DPLL_BYPASSACK_SEL[2:0]</a> MULT 7. <a href="#">CONTROL_CONF_DPLL_IDLE_SEL[2:0]</a> MULT	0x-
8. Choose to gate all the observable clocks at DPLL outputs simultaneously	<a href="#">CONTROL_HWOBS_CONTROL[8]</a> HWOBS_CLKOBS_GATE_ENABLE	0x-
9. Choose to associate a certain clockout signal to a given clockview channel	<a href="#">CONTROL_CONF_CLK_SEL0[2:0]</a> MULT through <a href="#">CONTROL_CONF_CLK_SEL2[2:0]</a> MULT	0x-
10. Choose to associate an sDMA signal to a given sDMA view channel	<a href="#">CONTROL_CONF_SDMA_REQ_SEL0[6:0]</a> MULT through <a href="#">CONTROL_CONF_SDMA_REQ_SEL3[6:0]</a> MULT	0x-

<sup>(1)</sup> To configure hwobs(0) channel to operate normally , HWOBS\_CLKDIV\_SEL bit value should be set different from 0.

<sup>(2)</sup> Set both bits to 0 to enable hardware observability. Set only one of them to 1 to gate hwobs ports according to output state required.

<sup>(3)</sup> The modules which belong to this group are: Cortex-A9 MPU subsystem, IVAHD, display subsystem , CM2, and ABE.

**Table 18-109. Configure Hardware Observability Features (continued)**

Step	Register/Bit Field/Programming Model	Value
11. Set the appropriate pad configuration bit fields to associate hw_dbgn pad function to output pins and configure additional output pad features	See <a href="#">Section 18.4.11, Hardware Observability</a> and <a href="#">Section 18.4.8, Pad Functional Multiplexing and Configuration</a> , for more information.	See <a href="#">Section 18.4.8, PAD Functional Multiplexing and Configuration</a> for more information

See [Section 18.4.11, Hardware Observability](#), for more details on different functionalities and registers associated with hardware observability features.

#### 18.5.1.2.4 Off Mode Preliminary Settings

This section describes configurations of PADs to work in off mode. The following actions must be performed once, and remain valid for all device OFF <-> ON transitions.

**Table 18-110. Setting PADS Off Mode Through Padconfiguration Registers**

Step	Register/ bit field / Programming Model	Value
1. Set OFFMODEPULLTYPESELECT bit	CONTROL_CORE_PAD0_X_PAD1_Y[29,13] Select pullup/down type when PAD in off mode	0b-
2. Set OFFMODEPULLUDENABLE bit	CONTROL_CORE_PAD0_X_PAD1_Y[28,12] Enable/disable pullup/down feature when PAD in off mode	0b-
3. Set OFFMODEOUTVALUE bit	CONTROL_CORE_PAD0_X_PAD1_Y[27,11] Set off mode pad override value	0b-
4. Set OFFMODEENABLE bit (enable/disable PAD overriding capability in OFF mode)	CONTROL_CORE_PAD0_X_PAD1_Y[25,9] Set pad to keep its previous state (it had before going to off mode) or force pad output to a certain override value (OFFMODEOUTVALUE) when PAD in off mode	0b-
5. Set OFFMODEOUTENABLE bit	CONTROL_CORE_PAD0_X_PAD1_Y[26,10] Enable/disable output in off mode	0b-
6. Program a valid device ACTIVE pads configuration	See <a href="#">Table 18-111</a> for more details on ACTIVE pads configuration	
7. Set clock gating strategy	1. CONTROL_PADCONF_CORE_SYSCONFIG[3:2]IP_SYSCONFIG 2. CONTROL_PADCONF_WKUP_SYSCONFIG[3:2]IP_SYSCONFIG	0x2,0x3
8. Enable/disable the wake-up detection capability <sup>(1)</sup>	CONTROL_CORE_PAD0_X_PAD1_Y[30,14]	0b-

<sup>(1)</sup> When the wake-up detection is enabled for a pad, this pad is configured as input. Therefore, do not forget to write 0b1 in the OFFOUTENABLE bit to disable the output capability.

#### 18.5.1.2.5 Pad Configuration Programming Points

This section describes through an example the configurations of PADs necessary for working in active mode.

To configure the pad, ensure that the following steps are done:

- Identify signals required on the interface based on the target application.  
**Example:** To configure the UART2 interface on balls, the required signals are uart2\_tx, uart2\_rts, uart2\_cts, and uart2\_rx.
- Choose the pads used for those signals. Some signals could be available on several pads and/or may be multiplexed with other signals needed for another application. See [Section 18.4.8.3, Pad Multiplexing Register Fields](#).

**Example:** Unlike the UART2 interface signals - uart2\_rx and uart2\_tx, each of which is available on two pads, the uart2\_cts and uart2\_rts signals are available only on one pad each (MUXMODE=0b000). However the uart2\_cts is multiplexed with the MMC I/O signal sdmmc3\_clk and the uart2\_rts signals is multiplexed with the MMC I/O signal sdmmc3\_cmd on the same pad. Assume that the MMC I/O 3 interface is also required in the system. Therefore, for the MMC I/O interface signals, pads must be

used where those signals are not multiplexed with a UART2 signal if possible. In this case the solution is to use sdmmc3\_clk and sdmmc3\_cmd on another two pads of the device - usbb2\_ulpitll\_dat7 and usbb2\_ulpitll\_dat6, configuring (MUXMODE=0b010).

- Identify the pad configuration registers associated with the pads to be used in the application. See [Section 18.4.8.3, Pad Multiplexing Register Fields](#).

**Example:** Under the previous hypothesis, the pad configuration registers to program are:

- uart2\_rts: [CONTROL\\_CORE\\_PAD0\\_UART2\\_CTS\\_PAD1\\_UART2\\_RTS\[31:16\]](#)
- uart2\_cts: [CONTROL\\_CORE\\_PAD0\\_UART2\\_CTS\\_PAD1\\_UART2\\_RTS\[15:0\]](#)
- uart2\_tx: [CONTROL\\_CORE\\_PAD0\\_UART2\\_RX\\_PAD1\\_UART2\\_TX\[31:16\]](#)
- uart2\_rx: [CONTROL\\_CORE\\_PAD0\\_UART2\\_RX\\_PAD1\\_UART2\\_TX\[15:0\]](#)

**Table 18-111. ACTIVE PADS Configuration Points**

Step	Register/ bit field / Programming Model	Value
1. Configure MUXMODE field in pad configuration registers associated with the pads used	1. <a href="#">CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS[18:16]</a> UART2_RTS_MUXMODE	0b000 0b000
	2. <a href="#">CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS[2:0]</a> UART2_CTS_MUXMODE	0b000 (0b010)
	3. <a href="#">CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX[18:16]</a> UART2_TX_MUXMODE	0b000 (0b010)
	4. <a href="#">CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX[2:0]</a> UART2_RX_MUXMODE	
2. Select the type of the internal pullup/down resistor <sup>(1)</sup>	1. <a href="#">CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX[4]</a> UART2_RX_PULLTYPESELECT	0b1 (pullup selected)
	2. <a href="#">CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS[2:0]</a> UART2_CTS_PULLTYPESELECT	0b1 (pullup selected)
3. Enable/Disable pullup/down feature of the pad <sup>(2)</sup>	1. <a href="#">CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX[3]</a> UART2_RX_PULLUDENABLE	0b1 (Pull feature enabled)
	2. <a href="#">CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS[3]</a> UART2_CTS_PULLUDENABLE	0b1 (Pull feature enabled)
4. Set the direction of the pin signal	1. <a href="#">CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX[8]</a> UART2_RX_INPUTENABLE	0b1 (input pin)
	2. <a href="#">CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS[8]</a> UART2_CTS_INPUTENABLE	0b1 (input pin)
	3. <a href="#">CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX[24]</a> UART2_TX_INPUTENABLE	0b0 (output pin)
	4. <a href="#">CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS[24]</a> UART2_RTS_INPUTENABLE	0b0 (output pin)

<sup>(1)</sup> It is recommended to use internal pullup/down resistor if pad is used as input and external pullup/down is not used.

<sup>(2)</sup> Pullup/down feature is automatically disabled if pad is used as an output, regardless of the value of PULLUDENABLE.

**NOTE:** The order for setting the previous pad configuration bits is not important.

## 18.6 Control Module Register Manual

### 18.6.1 Control Module Instance Summary

Table 18-112 lists the base address and address space for the control module instances.

**Table 18-112. Control Module Instance Summary**

Module instance	Base Address	Size	Description
SYSCTRL_GENERAL_C ORE	0x4A00 2000	4KB	Module
SYSCTRL_GENERAL_W KUP	0x4A30 C000	4KB	Module
SYSCTRL_PADCONF_C ORE	0x4A10 0000	4KB	Module
SYSCTRL_PADCONF_W KUP	0x4A31 E000	4KB	Module

**NOTE:** All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little-endian encoding).

## Mailbox

---

---

---

This chapter describes the Mailbox module in the device.

Topic	Page
<b>19.1 Mailbox Overview .....</b>	<b>3876</b>
<b>19.2 Mailbox Integration .....</b>	<b>3878</b>
<b>19.3 Mailbox Functional Description .....</b>	<b>3882</b>
<b>19.4 Mailbox Programming Guide .....</b>	<b>3888</b>
<b>19.5 Mailbox Register Manual .....</b>	<b>3891</b>

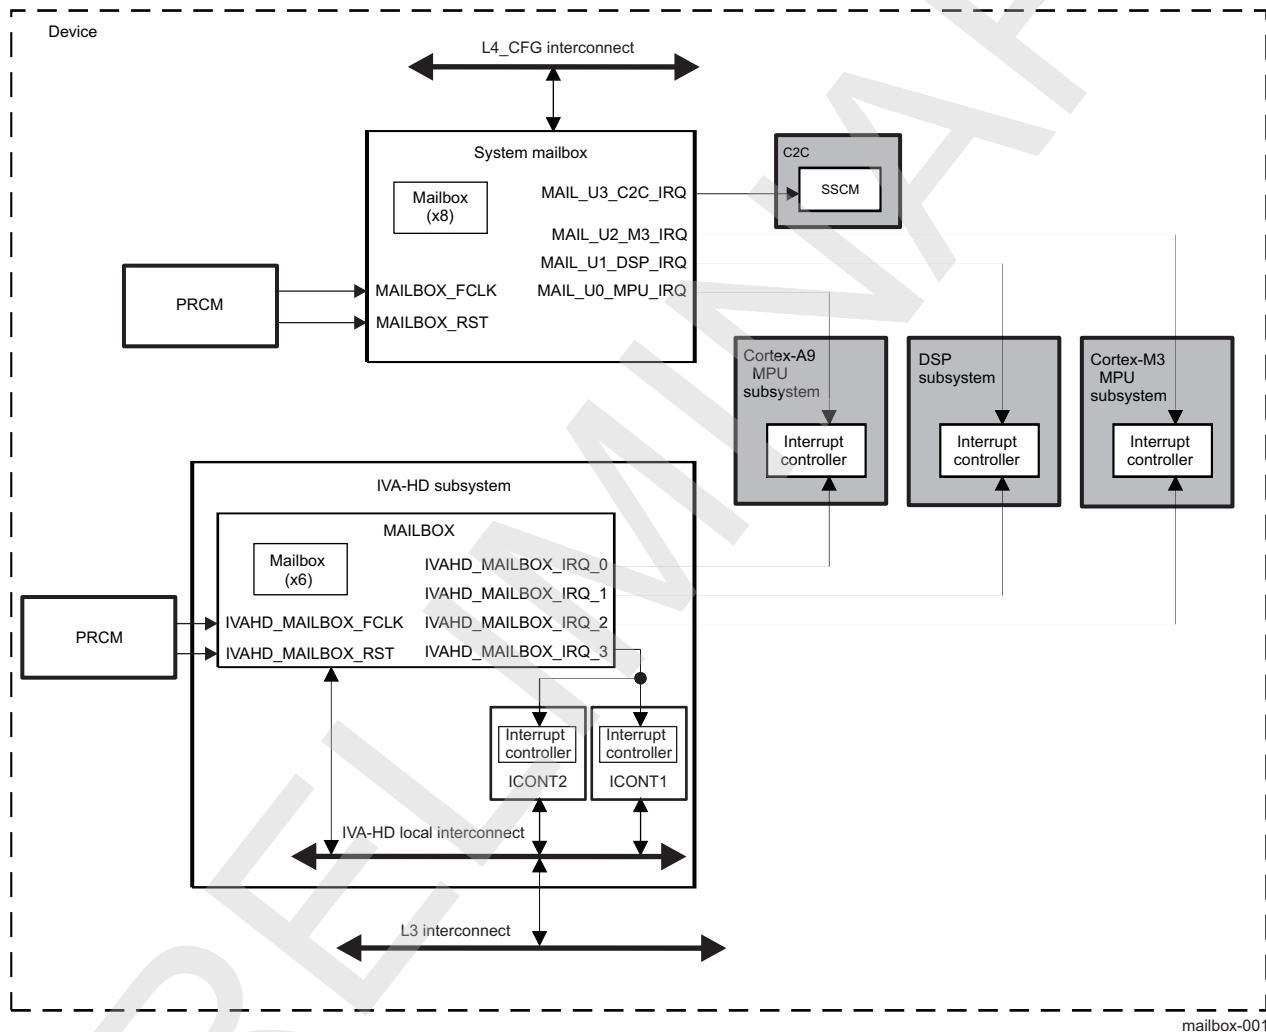

## 19.1 Mailbox Overview

Communication between the on-chip processors of the device uses a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors through a set of registers and associated interrupt signals by sending and receiving messages (mailboxes).

Figure 19-1 shows an overview of the mailbox module.

**Figure 19-1. Mailbox Overview**

mailbox-001

There are two mailbox module instances in the device:

- System mailbox - used for Cortex-A9 microprocessor unit (Cortex-A9 MPU), digital signal processor (DSP) and Cortex-M3 microprocessor unit (Cortex-M3 MPU) communications.
- IVA-HD mailbox - used for communication between one internal to the IVA-HD subsystem user (imaging controller 1 - ICONT1, or imaging controller 2 - ICONT2) and three external to the IVA-HD subsystem users (Cortex-A9 MPU, DSP and Cortex-M3 MPU). This communication is insured through three pairs of mailboxes.

The mailbox module includes the following features:

- Three users for the system mailbox instance (Cortex-A9 MPU, DSP and Cortex-M3 MPU)/four users for the IVA-HD mailbox instance (ICONT1/ICONT2, Cortex-A9 MPU, DSP and Cortex-M3 MPU)

- Eight mailbox message queues for the system mailbox instance/six mailbox message queues for the IVA-HD mailbox instance
- Flexible assignment of receiver and sender for each mailbox through interrupt configuration
- Three interrupts (one per user) for the system mailbox instance/four interrupts (one per user) for the IVA-HD mailbox instance
- 32-bit message width
- Four-message FIFO depth for each message queue
- Message reception and queue-not-full notification using interrupts
- Support of 16-/32-bit addressing scheme
- Power management support

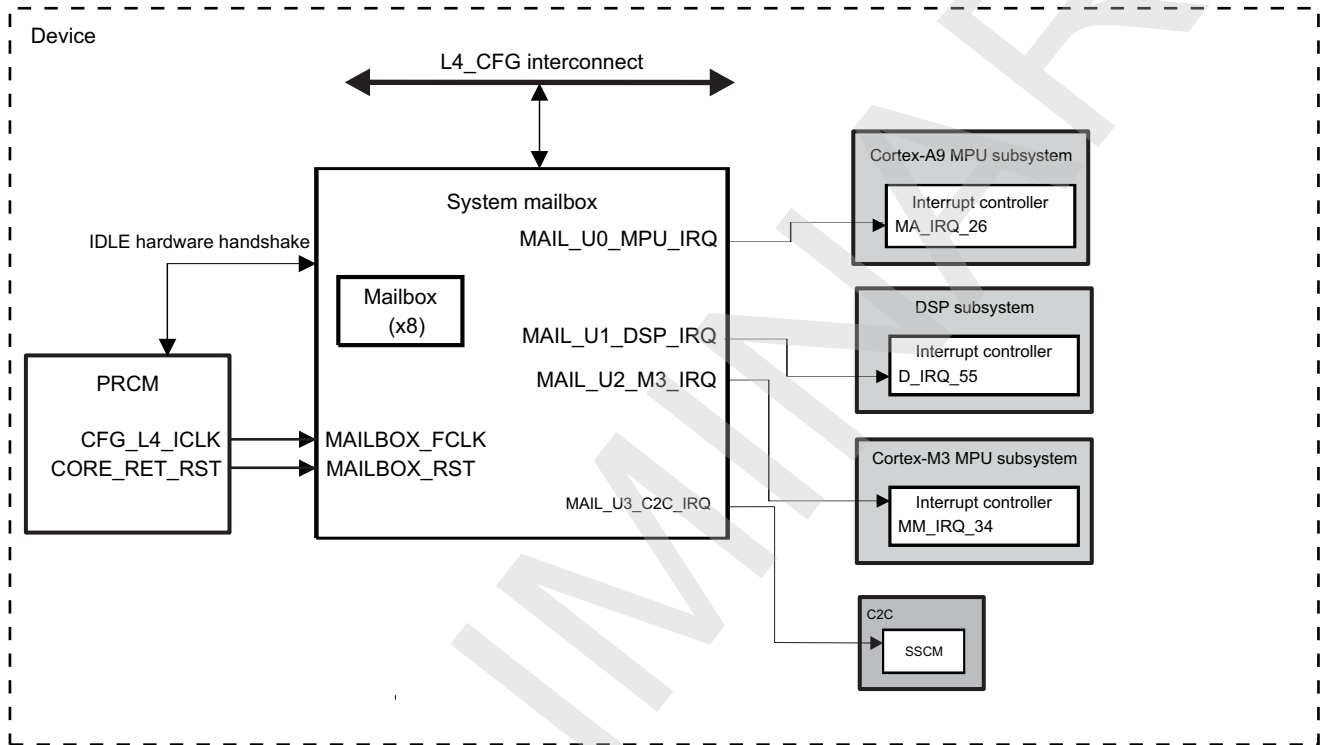

## 19.2 Mailbox Integration

This section describes the mailbox integration in the device, including information about clocks, resets, and hardware requests.

### 19.2.1 System Mailbox Integration

Figure 19-2 shows the system mailbox integration.

**Figure 19-2. System Mailbox Integration**

mailbox-002

**NOTE:** For more information about the IDLE hardware handshake, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 19-1](#) through [Table 19-3](#) summarize the system mailbox integration in the device.

**Table 19-1. Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
SYSTEM_MAILBOX	PD_CORE	NA	L4_CFG

**Table 19-2. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SYSTEM_MAILBOX	MAILBOX_FCLK	CFG_L4_ICLK	PRCM	System mailbox functional/interface clock. For information about PRCM clock gating and management, see <a href="#">Section 3.6.14, CD_L4_CFG Clock Management</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SYSTEM_MAILBOX	MAILBOX_RST	CORE_RET_RST	PRCM	System mailbox hardware reset. For information about PRCM reset sources and distribution, see <a href="#">Section 3.5.4, Reset Domains</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .

**Table 19-3. Hardware Requests**

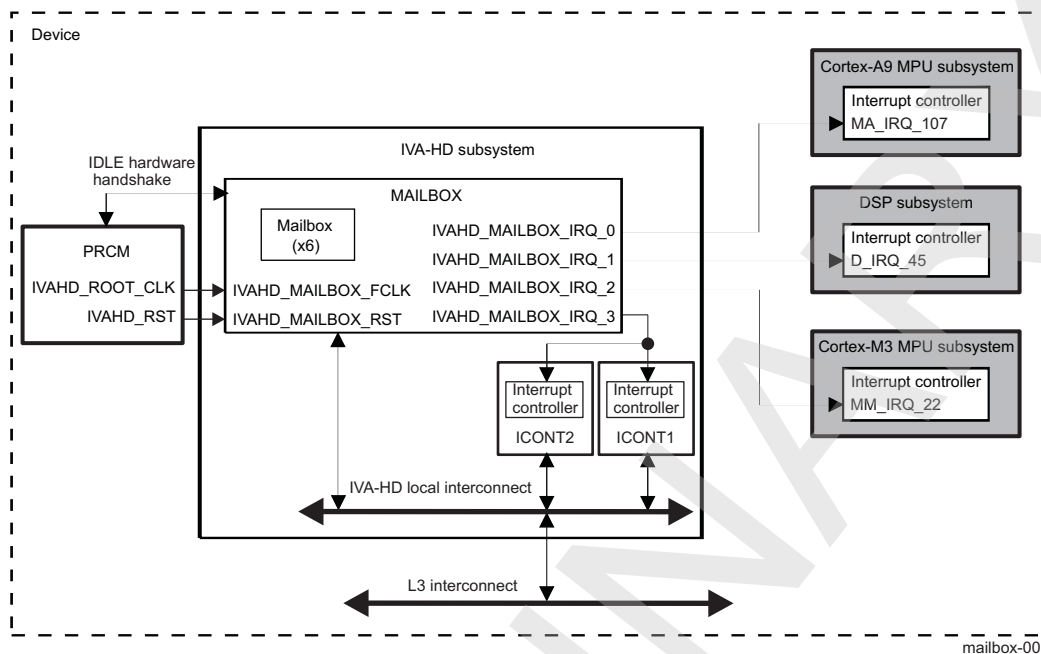

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
SYSTEM_MAILBOX	MAIL_U0_MPU_IRQ	MA_IRQ_26	Cortex-A9	System mailbox user 0 interrupt request. For information about Cortex-A9 MPU interrupt mapping, see <a href="#">Section 17.3.2, Interrupt Requests to the Cortex-A9 MPU Interrupt Controller</a> , in <a href="#">Chapter 17, Interrupt Controllers</a> .
	MAIL_U1_DSP_IRQ	D_IRQ_55	DSP	System mailbox user 1 interrupt request. For information about DSP interrupt mapping, see <a href="#">Section 5, DSP Subsystem</a> , in <a href="#">Chapter 5, DSP Subsystem</a> .
	MAIL_U2_M3_IRQ	MM_IRQ_34	Cortex-M3	System mailbox user 2 interrupt request. For information about Cortex-M3 MPU interrupt mapping, see <a href="#">Section 17.3.2, Interrupt Requests to the Cortex-M3 MPU Interrupt Controller</a> , in <a href="#">Chapter 17, Interrupt Controllers</a> .
	MAIL_U3_C2C_IRQ	C2C_SSCM_GPI_1	C2C INTC	Interrupt to the SSCM of C2C
No DMA Requests				

**NOTE:** For information about interrupt source description, see [Section 19.3.4, Interrupt Requests](#).

## 19.2.2 IVA-HD Mailbox Integration

[Figure 19-3](#) shows the IVA-HD mailbox integration.

Figure 19-3. IVA-HD Mailbox Integration

**NOTE:** For more information about the IDLE hardware handshake, see [Section 3.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**NOTE:** The two imaging controllers - ICONT1 and ICONT2, are mapped on a shared interrupt line. The choice between them is done by masking mailbox interrupt on ICONT1 or ICONT2. For more information, see [IVA-HD Imaging Controller](#) in [Chapter 6, IVA-HD Subsystem](#).

Table 19-4 through Table 19-6 summarize the IVA-HD mailbox integration in the device.

Table 19-4. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
IVAHD_MAILBOX	PD_IVAHD	NA	IVA-HD local interconnect

Table 19-5. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
IVAHD_MAILBOX	IVAHD_MAILBOX_FCLK	IVAHD_CLK	PRCM	IVA-HD mailbox functional/interface clock.

IVAHD_MAILBOX	IVAHD_MAILBOX_IRQ_0	MA_IRQ_107	Cortex-A9	IVA-HD mailbox user 0 interrupt request

**Table 19-6. Hardware Requests (continued)**

IVAHD_MAILBOX_IRQ_1	D_IRQ_45	DSP	IVA-HD mailbox user 1 interrupt request
IVAHD_MAILBOX_IRQ_2	MM_IRQ_22	Cortex-M3	IVA-HD mailbox user 2 interrupt request
IVAHD_MAILBOX_IRQ_3	IRQ#11	ICONT1/ICONT2	IVA-HD mailbox user 3 interrupt request. For information about ICONT1/ICONT2 interrupt mapping, see , <i>ICONT</i> .
<b>No DMA Requests</b>			

**NOTE:** For information about interrupt source description, see [Section 19.3.4, Interrupt Requests](#).

## 19.3 Mailbox Functional Description

**NOTE:** In the mailbox functional description,  $u$  is the user number and  $m$  is the mailbox number as follows:

- for the system mailbox module instance,  $u=0$  to 2 and  $m=0$  to 7
- for the IVA-HD mailbox module instance,  $u=0$  to 3 and  $m=0$  to 5

The mailbox module provides a means of communication through message queues among the users (depending on the mailbox module instance). The individual mailbox modules (8 for the system mailbox instance, 6 for the IVA-HD mailbox instance), or FIFOs, can associate (or de-associate) with any of the processors using the [MAILBOX\\_IRQENABLE\\_SET\\_u](#) (or [MAILBOX\\_IRQENABLE\\_CLR\\_u](#)) register.

### CAUTION

For the IVA-HD mailbox instance, communication is possible only if one of the users is ICONT1 or ICONT2.

The mailbox module includes the following user subsystems:

- User 0: Cortex-A9 MPU subsystem ( $u = 0$ )
- User 1: DSP subsystem ( $u = 1$ )
- User 2: Cortex-M3 MPU subsystem ( $u = 2$ )
- User 3:
  - IVA-HD subsystem ( $u = 3$ ) - only available to the IVA-HD mailbox instance
  - Mailbox subsystem - only available to SSCM module of C2C interface

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers.

Each [MAILBOX\\_IRQSTATUS\\_RAW\\_u](#)/[MAILBOX\\_IRQSTATUS\\_CLR\\_u](#) interrupt status register corresponds to a particular user.

For the system mailbox instance, a user can query its interrupt status register through the L4\_CFG interconnect.

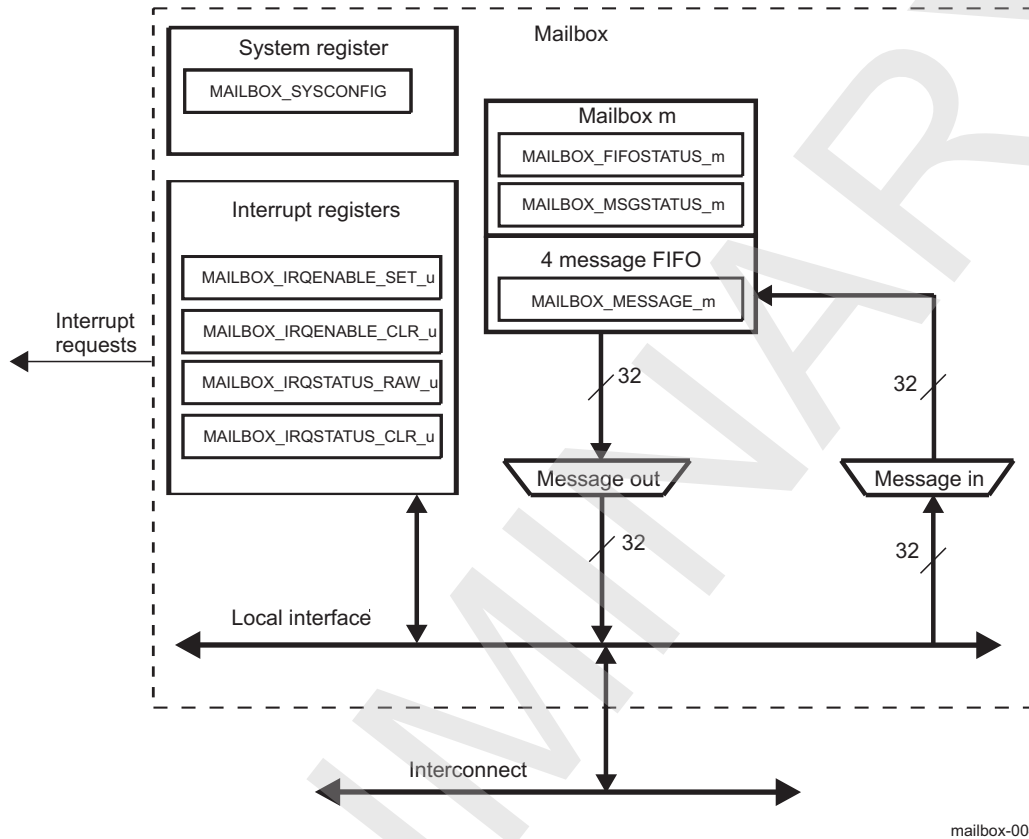

For the IVA-HD mailbox instance, a user can query its interrupt status register as follows:

- Cortex-A9 MPU and Cortex-M3 MPU - through the L3 interconnect
- ICONT1/ICONT2 and DSP - private access (directly through the IVA-HD local interconnect)

### 19.3.1 Mailbox Block Diagram

Figure 19-4 shows the mailbox block diagram.

Figure 19-4. Mailbox Block Diagram

**NOTE:** The interrupt requests and the interconnect depend on the mailbox module instance. For more information, see [Section 19.2, Mailbox Integration](#).

### 19.3.2 Mailbox Software Reset

The mailbox module supports a software reset through the [MAILBOX\\_SYSCONFIG\[0\] SOFTRESET](#) bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the [MAILBOX\\_SYSCONFIG\[0\] SOFTRESET](#) bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

### 19.3.3 Mailbox Power Management

[Table 19-7](#) describes power-management features available for the mailbox module.

**NOTE:**

- For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.4, Clock Domain Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**Table 19-7. Local Power Management Features**

Feature	Registers	Description
Clock autogating	NA	Feature not available
Slave idle modes	<a href="#">MAILBOX_SYSCONFIG[3:2]</a> SIDLEMODE bit field	Force-idle, no-idle and smart-idle modes are available
Clock activity	NA	Feature not available
Master standby modes	NA	Feature not available
Global wake-up enable	NA	Feature not available
Wake-up sources enable	NA	Feature not available

The mailbox module can be configured using the [MAILBOX\\_SYSCONFIG\[3:2\]](#) SIDLEMODE bit field to one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE = 0x0): The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (SIDLEMODE = 0x1): The mailbox module never enters the idle state.
- Smart-idle mode (SIDLEMODE = 0x2): After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

### 19.3.4 Mailbox Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

**NOTE:** For more information about interrupt requests, see [Section 19.2, Mailbox Integration](#).

[Table 19-8](#) lists the event flags, and their mask, that can cause module interrupts.

**Table 19-8. Interrupt Events**

Non-Maskable Event Flag <sup>(1)</sup>	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
<a href="#">MAILBOX_IRQSTATUS_RAW_u[0+m*2]</a> NEWMSGSTATUSUUM Bm	<a href="#">MAILBOX_IRQSTATUS_CLR_u[0+m*2]</a> NEWMSGSTATUSUUM Bm	<a href="#">MAILBOX_IRQENABLE_CLR_u[0+m*2]</a> NEWMSGSTATUSUUM Bm	<a href="#">MAILBOX_IRQENABLE_SET_u[0+m*2]</a> NEWMSGSTATUSUUM Bm	Mailbox <i>m</i> receives a new message.
<a href="#">MAILBOX_IRQSTATUS_RAW_u[1+m*2]</a> NOTFULLSTATUSUUM Bm	<a href="#">MAILBOX_IRQSTATUS_CLR_u[1+m*2]</a> NOTFULLSTATUSUUM Bm	<a href="#">MAILBOX_IRQENABLE_CLR_u[1+m*2]</a> NOTFULLSTATUSUUM Bm	<a href="#">MAILBOX_IRQENABLE_SET_u[1+m*2]</a> NOTFULLSTATUSUUM Bm	Mailbox <i>m</i> message queue is not full.

<sup>(1)</sup> MAILBOX.MAILBOX\_IRQSTATUS\_RAW\_u register is mostly used for debug purposes.

**CAUTION**

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the [MAILBOX\\_IRQSTATUS\\_CLR\\_u](#) register.

Writing a logical 1 in a bit of the [MAILBOX\\_IRQSTATUS\\_CLR\\_u](#) register will also clear to 0 the corresponding bit in the appropriate [MAILBOX\\_IRQSTATUS\\_RAW\\_u](#) register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the [MAILBOX\\_IRQENABLE\\_SET\\_u](#) register. Events are reported in the appropriate [MAILBOX\\_IRQSTATUS\\_CLR\\_u](#) and [MAILBOX\\_IRQSTATUS\\_RAW\\_u](#) registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the [MAILBOX\\_IRQENABLE\\_CLR\\_u](#) register. Events are only reported in the appropriate [MAILBOX\\_IRQSTATUS\\_RAW\\_u](#) register.

In case of the [MAILBOX\\_IRQSTATUS\\_RAW\\_u](#) register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

### 19.3.5 Mailbox Assignment

#### 19.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the [MAILBOX\\_IRQENABLE\\_SET\\_u](#) register. The receiver reads the [MAILBOX\\_MESSAGE\\_m](#) register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the [MAILBOX\\_FIFOSTATUS\\_m](#) and/or [MAILBOX\\_MSGSTATUS\\_m](#) registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the [MAILBOX\\_IRQENABLE\\_SET\\_u](#) register, where *u* is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the [MAILBOX\\_FIFOSTATUS\\_m](#) or [MAILBOX\\_MSGSTATUS\\_m](#) registers
- Write the message to the corresponding [MAILBOX\\_MESSAGE\\_m](#) register, if space is available.

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate [MAILBOX\\_IRQENABLE\\_SET\\_u](#) register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the [MAILBOX\\_IRQSTATUS\\_CLR\\_u](#) register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the [MAILBOX\\_IRQSTATUS\\_CLR\\_u](#) register acknowledges, and subsequently clears, an interrupt.

**CAUTION**

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

## 19.3.6 Sending and Receiving Messages

### 19.3.6.1 Description

When a 32-bit message is written to the [MAILBOX\\_MESSAGE\\_m](#) register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

Queue overflow can be avoided by first reading the [MAILBOX\\_FIFOSTATUS\\_m](#) register to check that the mailbox message queue is not full before writing a new message to it.

Reading the [MAILBOX\\_MESSAGE\\_m](#) register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the [MAILBOX\\_MESSAGE\\_m](#) register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the [MAILBOX\\_MSGSTATUS\\_m](#) register.

## 19.3.7 16-Bit Register Access

### 19.3.7.1 Description

So that 16-bit processors can access the mailbox module, the module allows 16-bit register read and write access, with restrictions for the [MAILBOX\\_MESSAGE\\_m](#) registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02).

All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the [MAILBOX\\_MESSAGE\\_m](#) registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

#### CAUTION

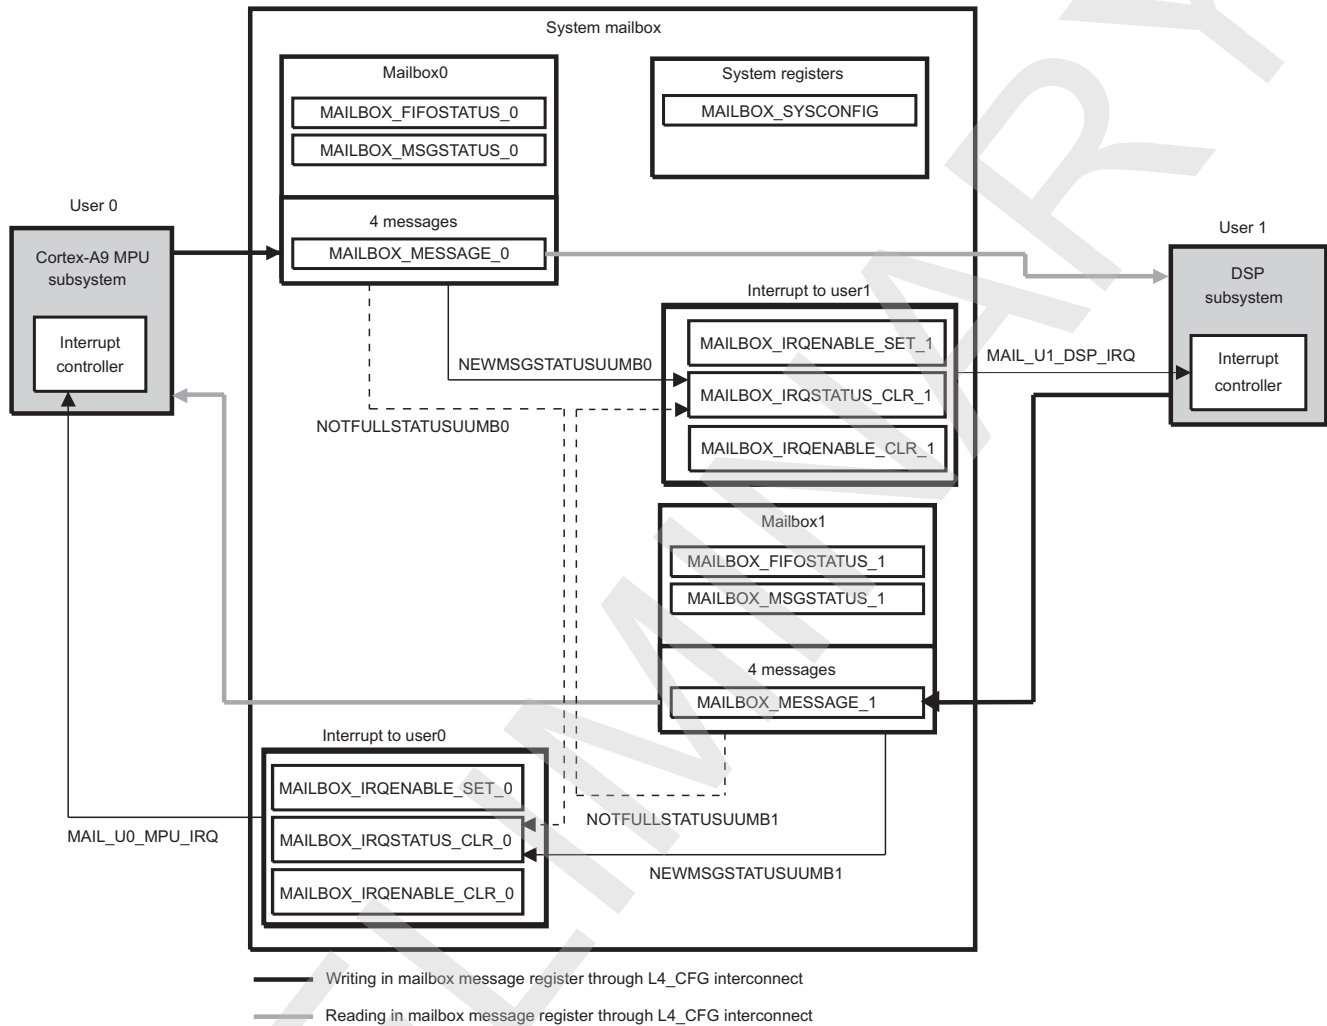

When using 16-bit accesses, it is critical to ensure that the mailbox used has only one assigned receiver and only one assigned sender.

When using 16-bit accesses to the [MAILBOX\\_MESSAGE\\_m](#) registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is because of the update operation by the message FIFO of the [MAILBOX\\_MSGSTATUS\\_m](#) registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a [MAILBOX\\_MESSAGE\\_m](#) are accessed.

### 19.3.8 Example of Communication

Figure 19-5 shows an example of communication between Cortex-A9 MPU and DSP subsystems.

Figure 19-5. Example of Communication

mailbox-005

## 19.4 Mailbox Programming Guide

### 19.4.1 Mailbox Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

#### 19.4.1.1 Global Initialization

##### 19.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See [Section 19.2, Mailbox Integration](#), for further information.

**Table 19-9. Global Initialization of Surrounding Modules for System Mailbox**

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled. For more information, see <a href="#">Section 3.6.14</a> , <i>CD_L4_CFG Clock Domain</i> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Interrupt Controllers	Cortex-A9 MPU, or Cortex-M3 MPU, or DSP interrupt controller must be configured to enable the interrupt request generation to the Cortex-A9 MPU, or Cortex-M3 MPU, or DSP subsystem. For information about enabling interrupts in Cortex-A9 MPU INTC, see the <i>ARM Cortex™-A9 MPCore Technical Reference Manual</i> . For information about enabling interrupts in Cortex-M3 MPU INTC, see the <i>ARM Cortex™-M3 Technical Reference Manual</i> . For information about enabling interrupts in DSP INTC, see <a href="#">Chapter 5, DSP Subsystem</a> .
Interconnect	For information about L4-CFG interconnect configuration, see <a href="#">Section 13.3, L4 Interconnects</a> , in <a href="#">Chapter 13, Interconnect</a> .

**Table 19-10. Global Initialization of Surrounding Modules for IVA-HD Mailbox**

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled. For more information, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Interrupt Controllers	Cortex-A9 MPU, or Cortex-M3 MPU, or DSP, or ICONT1/ICONT2 interrupt controller must be configured to enable the interrupt request generation to the Cortex-A9 MPU, or Cortex-M3 MPU, or DSP, or IVA-HD subsystem. For information about enabling interrupts in Cortex-A9 MPU INTC, or Cortex-M3 MPU INTC, or DSP INTC, see <a href="#">Table 19-9, Global Initialization of Surrounding Modules for System Mailbox</a> . For information about enabling interrupts in ICONT1/ICONT2, see <i>ICONT</i> in <a href="#">Chapter 6, IVA-HD Subsystem</a> .
Interconnect	For information about L3 interconnect configuration, see <a href="#">Section 13.2, L3 Interconnects</a> , in <a href="#">Chapter 13, Interconnect</a> .

##### 19.4.1.1.2 Mailbox Global Initialization

###### 19.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

**Table 19-11. Mailbox Global Initialization**

Step	Register/ Bit Field / Programming Model	Value
Perform a software reset	<a href="#">MAILBOX_SYSCONFIG</a> [0] SOFTRESET	0x1
Wait until reset is complete	<a href="#">MAILBOX_SYSCONFIG</a> [0] SOFTRESET	= 0x0
Set idle mode configuration	<a href="#">MAILBOX_SYSCONFIG</a> [3:2] SIDLEMODE	0x-

## 19.4.1.2 Mailbox Operational Modes Configuration

### 19.4.1.2.1 Mailbox Processing modes

#### 19.4.1.2.1.1 Main Sequence - Sending a Message (Polling Method)

**Table 19-12. Sending a Message (Polling Method)**

Step	Register/ Bit Field / Programming Model	Value
<b>IF</b> : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x1
Wait until at least one message slot is available	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x0
<b>ELSE</b>		
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
<b>ENDIF</b>		

#### 19.4.1.2.1.2 Main Sequence - Sending a Message (Interrupt Method)

**Table 19-13. Sending a Message (Interrupt Method)**

Step	Register/ Bit Field / Programming Model	Value
<b>IF</b> : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x1
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[1+ m*2]	0x1
User (processor) can perform another task until interrupt occurs See <a href="#">Section 19.4.1.3.1</a> for interrupt handling in sending mode		
<b>ELSE</b>		
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
<b>ENDIF</b>		

#### 19.4.1.2.1.3 Main Sequence - Receiving a Message (Polling Method)

**Table 19-14. Receiving a Message (Polling Method)**

Step	Register/ Bit Field / Programming Model	Value
<b>IF</b> : Number of messages is not equal to 0	MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB	!= 0x0
Read message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
<b>ENDIF</b>		

#### 19.4.1.2.1.4 Main Sequence - Receiving a Message (Interrupt Method)

**Table 19-15. Receiving a Message (Interrupt Method)**

Step	Register/ Bit Field / Programming Model	Value
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[0 + m*2]	0x1
User (processor) can perform another task until interrupt occurs See <a href="#">Section 19.4.1.3.2</a> for interrupt handling in receiving mode		

### 19.4.1.3 Mailbox Events Servicing

#### 19.4.1.3.1 Events Servicing in Sending Mode

Table 19-16 describes the events servicing in sending mode.

**Table 19-16. Events Servicing in Sending Mode**

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1

#### 19.4.1.3.2 Events Servicing in Receiving Mode

Table 19-17 describes the events servicing in receiving mode.

**Table 19-17. Events Servicing in Receiving Mode**

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	0x1
<b>IF</b> : Number of messages is not equal to 0 ?	MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB	!= 0x0
Read message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
<b>ELSE</b>		
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	0x1
<b>ENDIF</b>		

## 19.5 Mailbox Register Manual

### 19.5.1 Mailbox Instance Summary

**Table 19-18. System Mailbox Instance Summary**

Module Name	Base Address L4_CFG Interconnect	Size
System Mailbox	0x4A0F 4000	4KB

**Table 19-19. IVAHD Mailbox Instance Summary**

Module Name	Base Address L3 Interconnect	Base Address DSP Subsystem Private Access	Base Address Private Access	Size
IVAHD Mailbox	0x5A05 A800	0x01E5 A800	0x008D A800	4KB

**NOTE:** Private access is an access that does not use the L3/L4 interconnects.

### 19.5.2 Mailbox Registers

#### 19.5.2.1 Mailbox Register Summary

## Memory Management Units

This chapter describes the memory management units (MMUs).

Topic	Page
<b>20.1 MMU Overview .....</b>	<b>3908</b>
<b>20.2 MMU Integration .....</b>	<b>3909</b>
<b>20.3 MMU Functional Description .....</b>	<b>3912</b>

## 20.1 MMU Overview

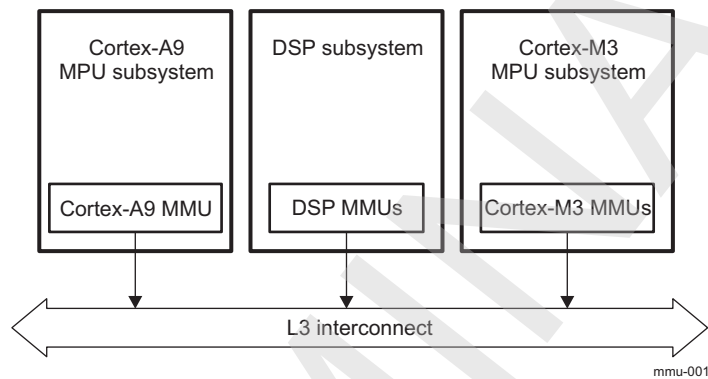

A memory management unit (MMU) is a hardware component responsible for handling accesses to memory requested by a processing unit. MMU functions include translation of virtual addresses to physical addresses (that is, virtual memory management) and cache control.

The device contains the following MMUs:

- In DSP - L1 Shared cache MMU and attribute MMU.
- In Dual Cortex-M3 MPU Subsystem - L1 Shared cache MMU and L2 MMU
- Cortex-A9 MMU

Figure 20-1 shows the MMU instances in the device.

**Figure 20-1. Device MMU Instances**

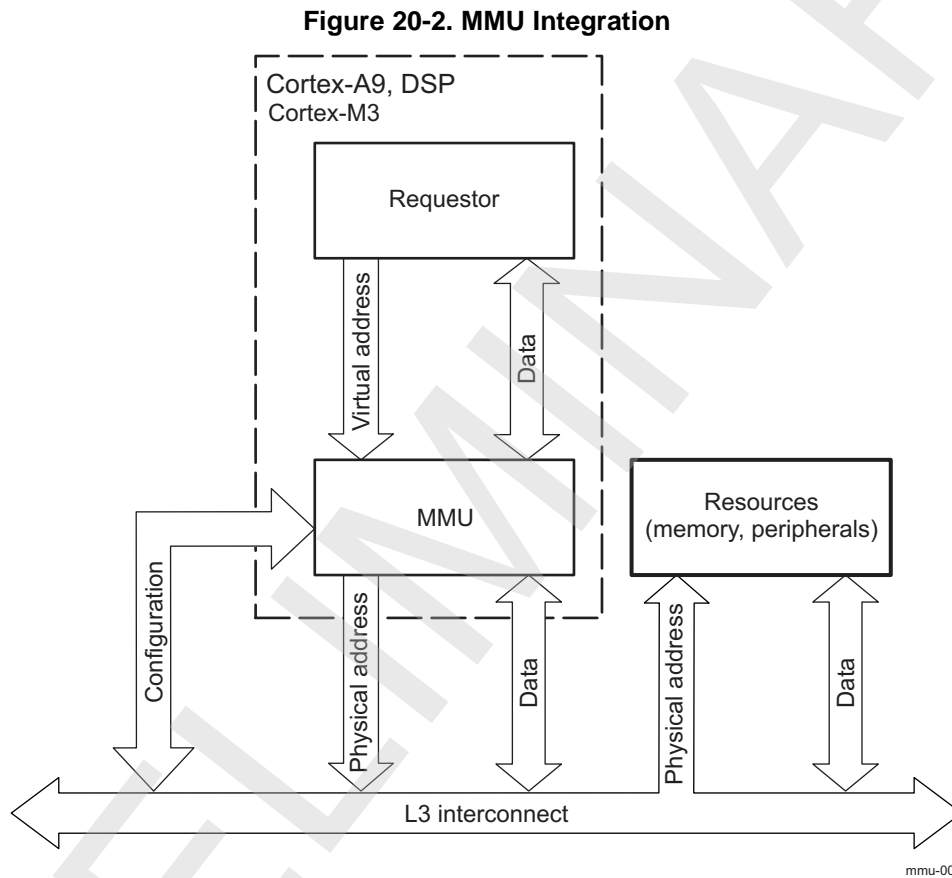

## 20.2 MMU Integration

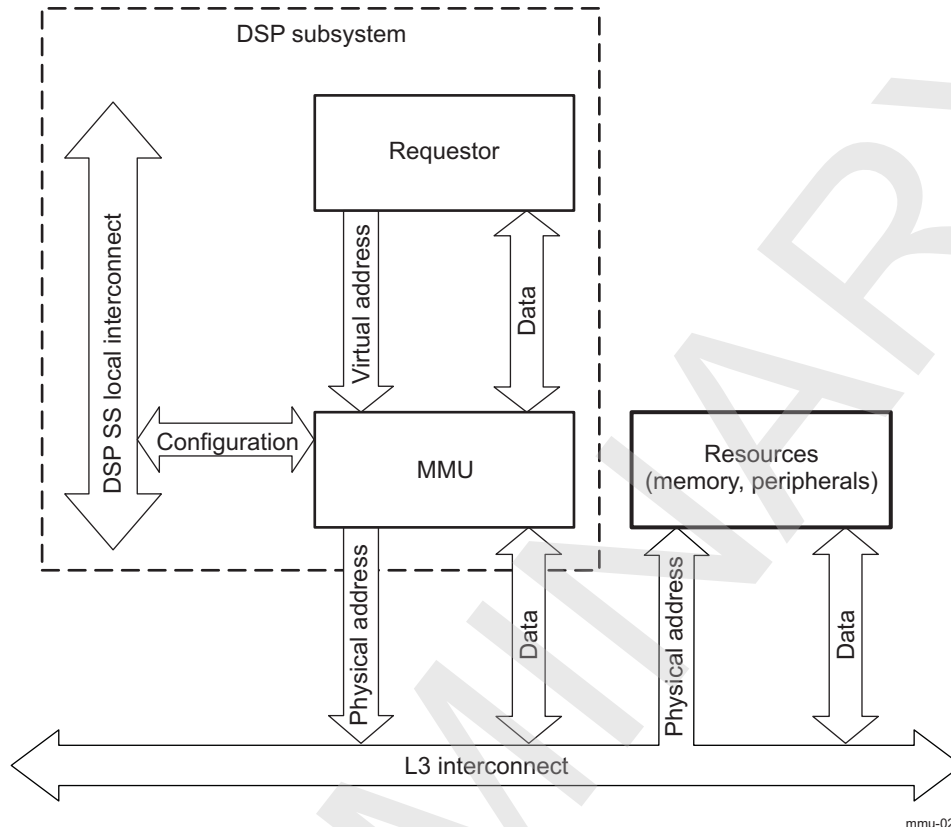

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

The MMU communicates accesses from the requestor (DSP, Cortex-M3 microprocessor unit (MPU), or Cortex-A9 MPU) to the L3 main interconnect, performing virtual to physical address translation. Although all MMUs are programmed (configured) through the L3 interconnect, the DSP MMU can be programmed both through the L3 interconnect or through the DSP local interconnect. DSP MMU and Cortex-M3 MMU error conditions are signaled as interrupts to the system main processor Cortex-A9 MPU.

Figure 20-2 shows typical MMU integration.

**NOTE:** All MMUs are programmed through the L3 interconnect.

**Figure 20-3. DSP MMU Integration**

**NOTE:** The DSP MMU can be programmed from both the DSP local interconnect and from the L3 interconnect.

Table 20-1 through Table 20-3 summarize the MMU integration in the various modules of the device.

**Table 20-1. Integration Attributes**

Module Instance	Power Domain
CORTEXM3_L2MMU and CORTEXM3_SCACHE_MMU	PD_CORE
CORTEXA9_MMU	PD_MPU

**Table 20-2. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
CORTEXA9_MMU	ARM_FCLK	MPU_DPLL_CLK	MPU DPLL	Internal clock in the Cortex-A9 MPU subsystem; supplies the MMU in Cortex-A9.
CORTEXM3_L2MMU and CORTEXM3_SCACHE_MMU	MPU_M3_CLK	MPU_M3_CLK	PRCM	External clock from the power, reset, and clock management (PRCM) module; supplies the shared cache MMU and L2 MMU in Cortex-M3.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
CORTEXM3_L2MMU	CORTEXM3_PWRON_RST	CORTEXM3_PWRON_RST	PRCM	Power-on reset signal for the Cortex-M3 MPU subsystem
	CORTEXM3_RST3	CORTEXM3_RST3	PRCM	Reset signal to the L2 MMU

**Table 20-2. Clocks and Resets (continued)**

CORTEXM3_SCACHE_MMU	CORTEXM3_RST3	CORTEXM3_RST3	PRCM	Reset signal for the shared cache MMU
	CORTEXM3_RET_RST	CORTEXM3_RET_RST	PRCM	Retention reset signal for the Cortex-M3 MPU subsystem
CORTEXA9_MMU	MPU_PWRON_RST	MPU_PWRON_RST	PRCM	Power-on reset signal to the MMU and the rest of the Cortex-A9 MPU subsystem
	MPU_RST	MPU_RST	PRCM	Reset signal to the MMU and the rest of the Cortex-A9 MPU subsystem

**Table 20-3. Hardware Requests**

Module Instance	Source Signal Name	Interrupt Requests		Description
		Destination Signal Name	Destination	
CORTEXM3_L2MMU	CORTEXM3_MMU_IRQ	MA_IRQ_100	MPU_INT C	Cortex-M3 MPU L2MMU interrupt to the main MPU subsystem
	XLATE_MMU_FAULT	MM_IRQ_0	CortexM3_INT C	Internal interrupt from the L2MMU to the Cortex-M3 interrupt controller (INTC)
CORTEXM3_SCACHE_MMU	SHARED_CACHE_MMU_C PU_INT	MM_IRQ_1	CortexM3_INT C	Internal interrupt from the shared cache MMU to the CortexM3 INTC

**NOTE:**

- For a description of the interrupt source, see [Section 20.3.5, Interrupt Requests](#).

There are 5 MMU modules in the device:

- Shared cache MMU – there are two Share cache MMUs, one in the Cortex-M3 MPU and other in DSP subsystem. Refer to the corresponding chapters for more information.
- L2 MMUs – there are two L2 MMUs, one in the Cortex-M3 MPU and other in DSP subsystem. The L2 MMUs are directly operating with the L3 interconnect (shared device memory space). These L2 MMUs are described in this chapter.
- Cortex-A9 MMU – this MMU is located in the ARM Cortex-A9 processor. For information about this MMU, see the ARM® Cortex™-A9 MPCore Technical Reference Manual.

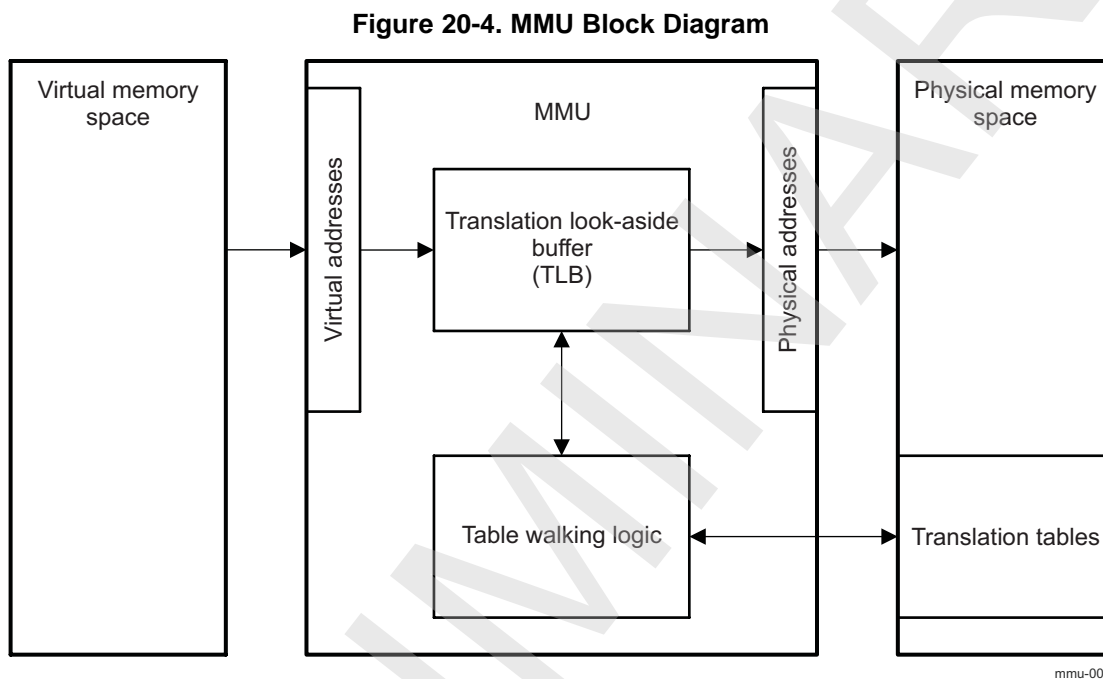

**NOTE:** There is PAT module in the Dynamic Memory Manager, which has similar to the MMU functionality. Refer to the DMM chapter, for more information.

## 20.3 MMU Functional Description

### 20.3.1 MMU Block Diagram

The MMU manages the virtual to physical address translation for external addresses, as well as endianness conversion. The MMU can be programmed through the L3 interconnect. MMU programming is expected to be accomplished by the Cortex-A9 MPU, except for the DSP MMU, of which the configuration can be accomplished through the DSP local interconnect.

Figure 20-4 is the MMU block diagram.

Each table entry describes the translation of one contiguous memory region. For a description of the structure of these tables, see [Section 20.3.1.2, Translation Tables](#).

Two major functional units exist in the MMU to provide address translation automatically based on the table entries:

- The table walker automatically retrieves the correct translation table entry for a requested translation. If two-level translation is used (for the translation of small memory pages), the table walker also automatically reads the required second-level translation table entry. The two-level translation is described later in the chapter.
- The translation look-aside buffer (TLB) stores recently used translation entries, acting like a cache of the translation table.

#### 20.3.1.1 MMU Address Translation Process

Whenever an address translation is requested (that is, for every access with the MMU enabled), the MMU first checks whether the translation is contained in the TLB, which acts like a cache storing recent translations. The TLB can also be programmed manually to ensure that time-critical data can be translated without delay.

If the requested translation is not in the TLB, the table-walking logic retrieves this translation from the translation table(s), and then updates the TLB. The address translation is then performed. [Figure 20-5](#) summarizes the process.

Figure 20-5. Translation Process

mmu-007

### 20.3.1.2 Translation Tables

The translation of virtual to physical addresses is based on entries in translation tables that define the following properties:

- Address translation, that is, the correspondence between virtual and physical addresses
- Size of the memory region the entry translates
- Endianness, data access size, and the mixed property of this memory region

The virtual addresses index the translation tables. Each virtual address corresponds to exactly one entry in the translation table.

#### 20.3.1.2.1 Translation Table Hierarchy

When developing a table-based address translation scheme, one of the most important design parameters is the memory page size described by each translation table entry. MMU instances support 4KB and 64KB pages, a 1MB section, and a 16MB supersection. Using bigger page sizes means a smaller translation table.

Using a smaller page size greatly increases the efficiency of dynamic memory allocation and defragmentation. That is why many operating systems (OSs) can operate on memory blocks as small as 4KB; however, the smaller size implies a more complex table structure.

A quick calculation shows that using 4KB memory pages with one translation table would require one million entries to span the entire 4GB address range. The table itself would be 32MB, a size that is not feasible.

However, using bigger pages greatly reduces the functionality of the OS memory management. Implementing a two-level hierarchy reconciles these two requirements. Within this hierarchy, one first-level translation table describes the translation properties based on 1MB memory regions.

Each of the entries in this first-level translation table can specify the following:

- The translation properties for a big memory section. This memory section can be either 1MB (section) or 16MB (supersection). In this case, all translation parameters are specified in the first-level translation table entry.

- A pointer to a second-level translation table that specifies individual translation properties based on smaller pages within the 1MB page of memory. These pages can be either 64KB (large page) or 4KB (small page). In this case, the actual translation parameters are specified in the second-level translation table entry. The first-level translation table entry specifies only the base address of the second-level translation table.

This hierarchical approach means that additional translation information for smaller pages must be provided only when the pages are actually used. [Figure 20-6](#) shows the hierarchy.

**Figure 20-6. Translation Hierarchy**

mmu-008

The structure of the first and second-level translation tables and their entries are described in more detail in [Section 20.3.1.2.2, First-Level Translation Table](#), and [Section 20.3.1.2.3, Two-Level Translation](#).

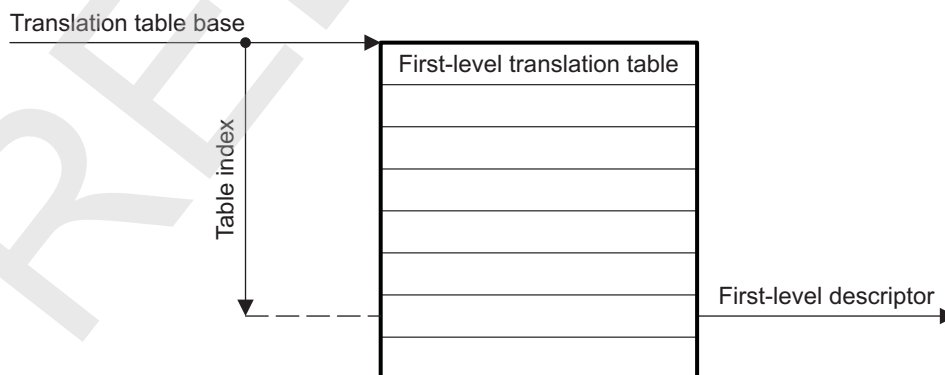

### 20.3.1.2.2 First-Level Translation Table

The first-level translation table describes the translation properties for 1MB sections. To describe a 4GB address range requires 4096 32-bit entries (so-called first-level descriptors).

The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table; that is, at least the last fourteen address bits must be zero.

The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address. [Figure 20-7](#) shows this mechanism.

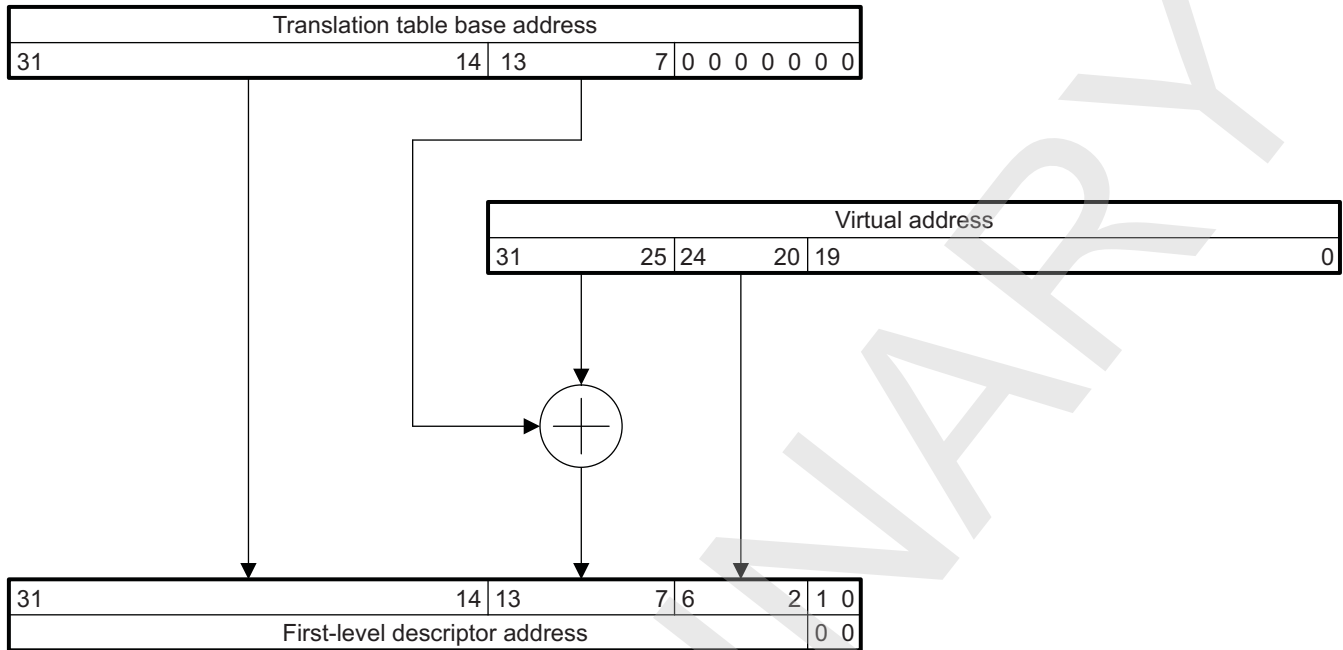

**Figure 20-7. First-level Descriptor Address Calculation**

mmu-009

To summarize, the translation table base and the translation table index together define the first-level descriptor address. [Figure 20-8](#) outlines the precise mechanism used to calculate this address.

Figure 20-8. Detailed First-level Descriptor Address Calculation

mmu-010

As an example of this mechanism, consider a translation table base address of 0x8000:0000 and a virtual address of 0x1234:5678. In this case, the first-level descriptor address is 0x8000:0000 + (0x123 <<2) = 0x8000:048C.

### 20.3.1.2.2.1 First-Level Descriptor Format

Each first-level descriptor provides either the complete address translation for 1MB or 16MB sections or provides a pointer to a second-level translation table for 4KB or 64KB pages. Table 20-4 shows the first-level descriptor format.

Table 20-4. First-Level Descriptor Format

First-Level Descriptor Format												
31:24	23:20	19	18	17	16	15	14:12	11:10	9:2	1	0	
X										0	0	Fault
Second-Level Translation Table Base Address									X	0	1	Page
Section Base Address		X	0	M	X	E <sup>(1)</sup>	X	ES	X	1	0	Section
Supersection Base Address		X	1	M	X	E	X	ES	X	1	0	Supersection
X										1	1	Fault

<sup>(1)</sup> See Table 20-42 for endianness limitations.

M = Mixed region: 0 = Page-based endianness, 1 = Access-based endianness

E = Endianness: 0 = Little endian, 1 = Big endian (endianness is locked on little endian)

ES = Element Size: 00 = 8-bit, 01 = 16-bit, 10 = 32-bit, 11 = No endianness conversion

X = Don't care

### 20.3.1.2.2.2 First-Level Page Descriptor Format

If a translation granularity smaller than 1MB is required, a two-level translation process is used. In this case, the first-level block descriptor specifies only the start address of a second-level translation table. The second-level translation table entries specify the actual translation properties.

### 20.3.1.2.2.3 First-Level Section Descriptor Format

Each section descriptor in the first-level translation table specifies the complete translation properties for a 1MB section or a 16MB supersection.

**NOTE:** Supersection descriptors must be repeated 16 times, because each descriptor in the first-level translation table describes 1MB of memory. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

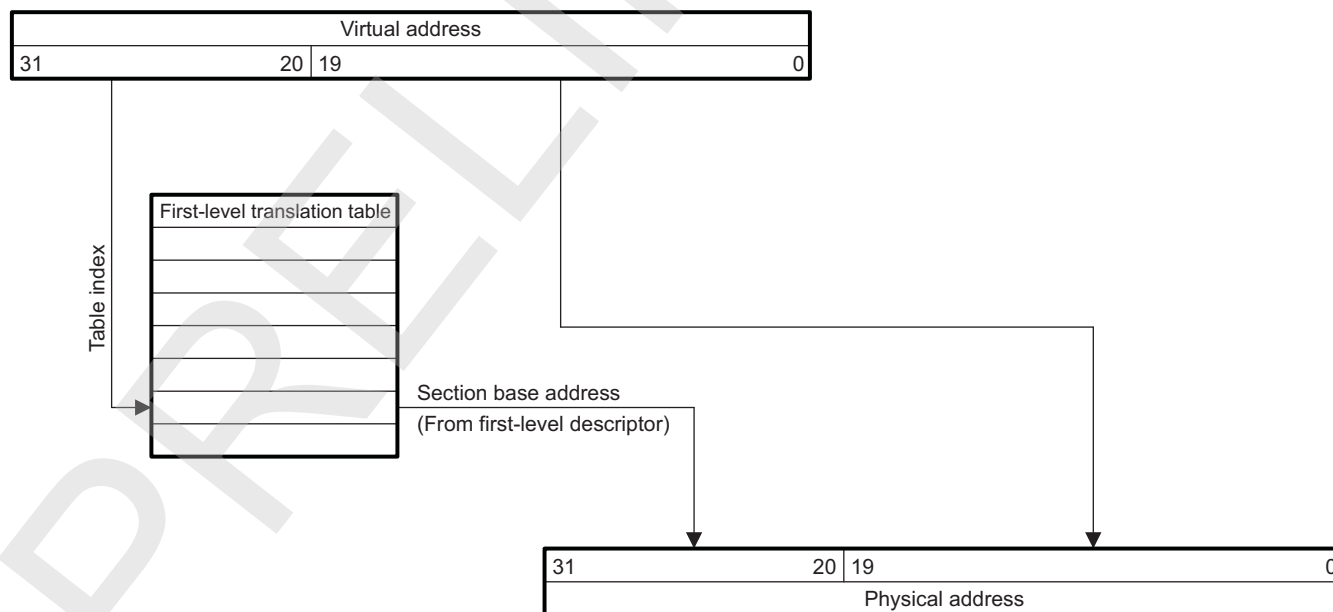

In addition to the address translation itself, three parameters are specified in the section descriptors:

- **Endianness**  
The *endianness* parameter specifies whether the memory section uses a big- or little-endian data format. This parameter is locked to little endian. See [Table 20-42](#) for more information.
- **Element size**  
The *element size* parameter can optionally specify the data access size (8, 16, or 32 bits) for all data items in the defined section.
- **Mixed region**  
The *mixed region* parameter specifies whether the information about the data access size is detected from the access itself (access-based detection) or if the specified element size parameter is used (page-based detection). For example, the specified element size parameter can be used when several smaller sized accesses are packed into a bigger sized access, such as two 16-bit accesses packed into one 32-bit access. In this case, with no specified data access size, 32 bits would be the access size detected, leading to an incorrect result. To avoid this problem, specify the data access size for the memory section.

### 20.3.1.2.2.4 Section Translation Summary

Sections and supersections can be translated based solely on the information in the first-level translation table. [Figure 20-9](#) summarizes the address translation process for a section.

**Figure 20-9. Section Translation Summary**

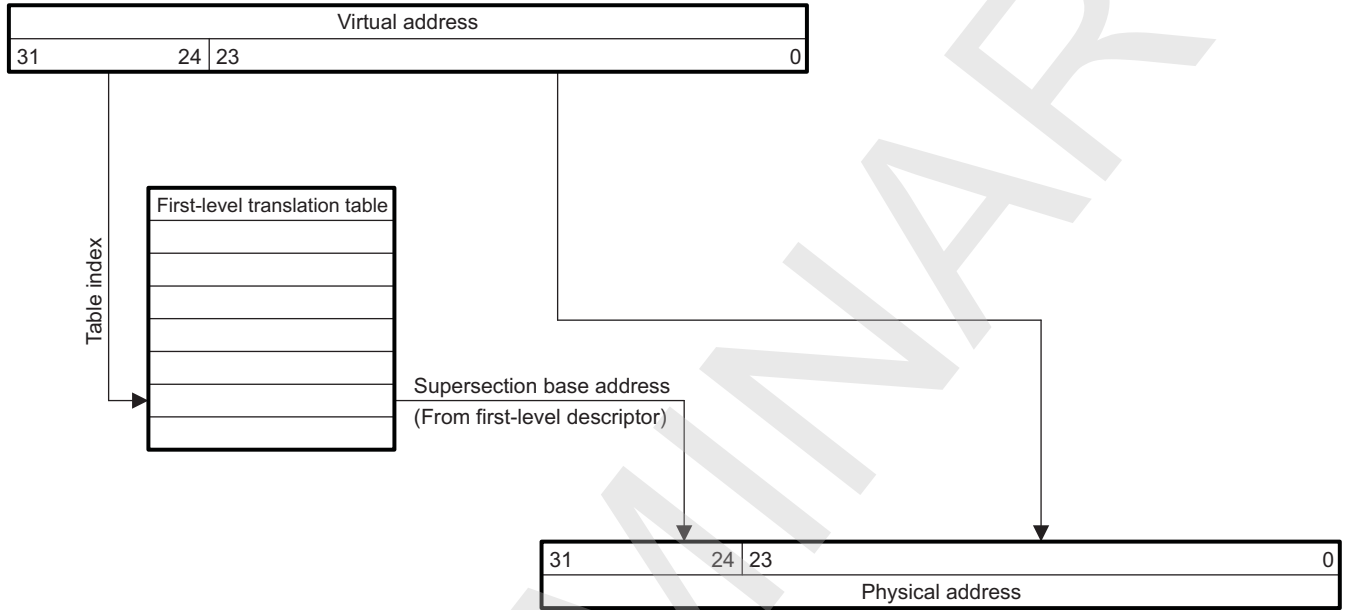

mmu-011

**20.3.1.2.2.5 Supersection Translation Summary**

The translation of a supersection is similar to the translation of a section. The difference is that for a supersection only bits 31 to 24 index into the first-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a supersection.

Figure 20-10 shows the translation mechanism for a supersection.

**Figure 20-10. Supersection Translation Summary**

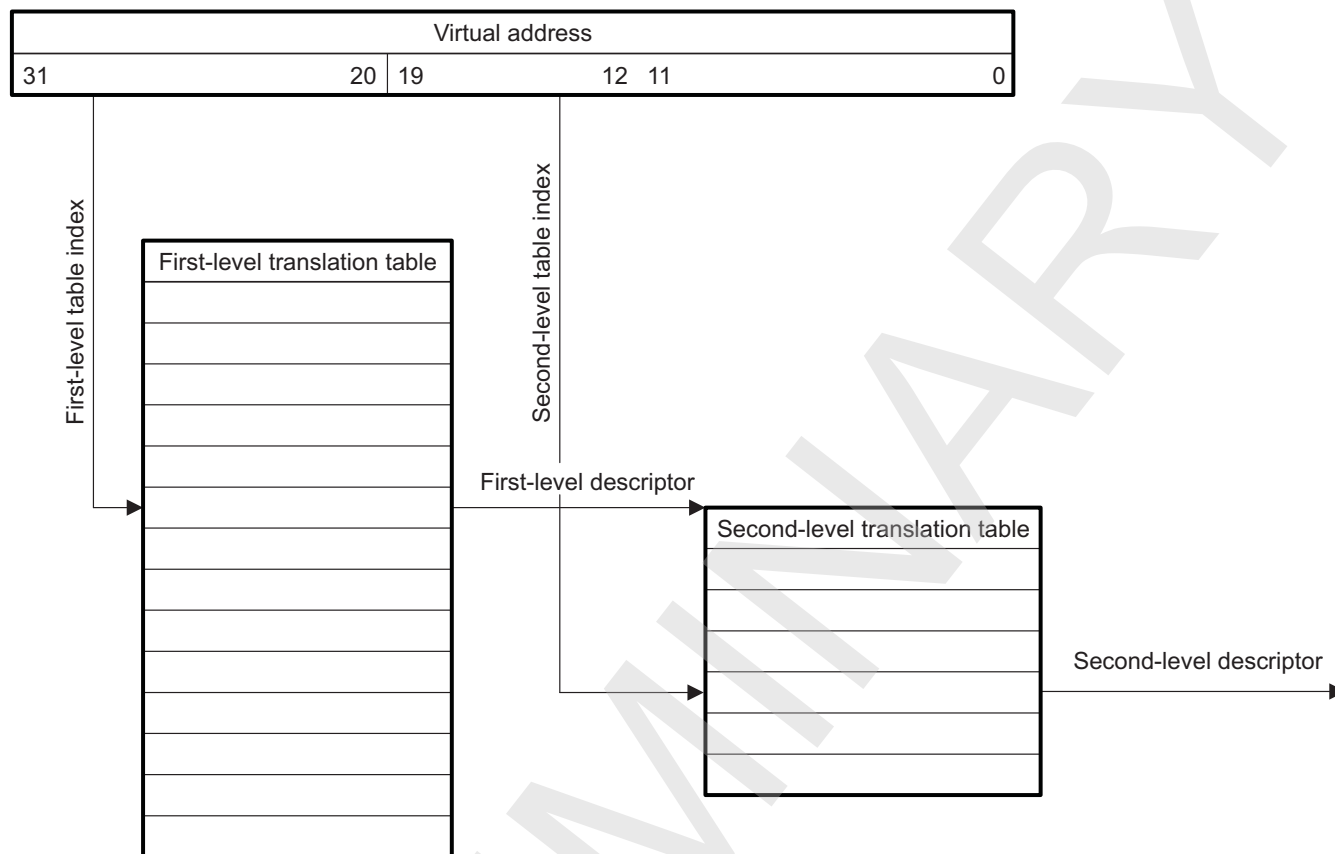

mmu-012

**20.3.1.2.3 Two-Level Translation**

Two-level translation is used when fine-grain granularity is required, that is, when memory sections smaller than 1MB are needed. In this case, the first-level descriptor provides a pointer to the base address of a second-level translation table. This second-level table is indexed by bits 19 to 12 of the virtual address. Figure 20-11 shows this indexing mechanism.

**Figure 20-11. Two-Level Translation**

mmu-013

Each second-level translation table describes the translation of 1MB of address space in pages of 64KB (large page) or 4KB (small page). It consists of 256 second-level descriptors describing 4KB each.

**NOTE:** In the case of a large page, the same descriptor must be repeated 16 times. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

**20.3.1.2.3.1 Second-Level Descriptor Format**

Similar to first-level section descriptors, second-level descriptors provide all of the necessary information for the translation of a large or small page. Table 20-5 shows the format of second-level descriptors. The translation parameters (endianness, element size, and mixed region) have the same meaning as those for sections.

**Table 20-5. Second-Level Descriptor Format**

Second-Level Descriptor Format											
31:16	15:12	11	10	9	8:6	5:4	3:2	1	0		
X									0	0	Fault
Large Page Base Address	X	M	X	E <sup>(1)</sup>	X	ES	X	0	1	Large Page	
Small Page Base Address		M	X	E	X	ES	X	1	X	Small Page	

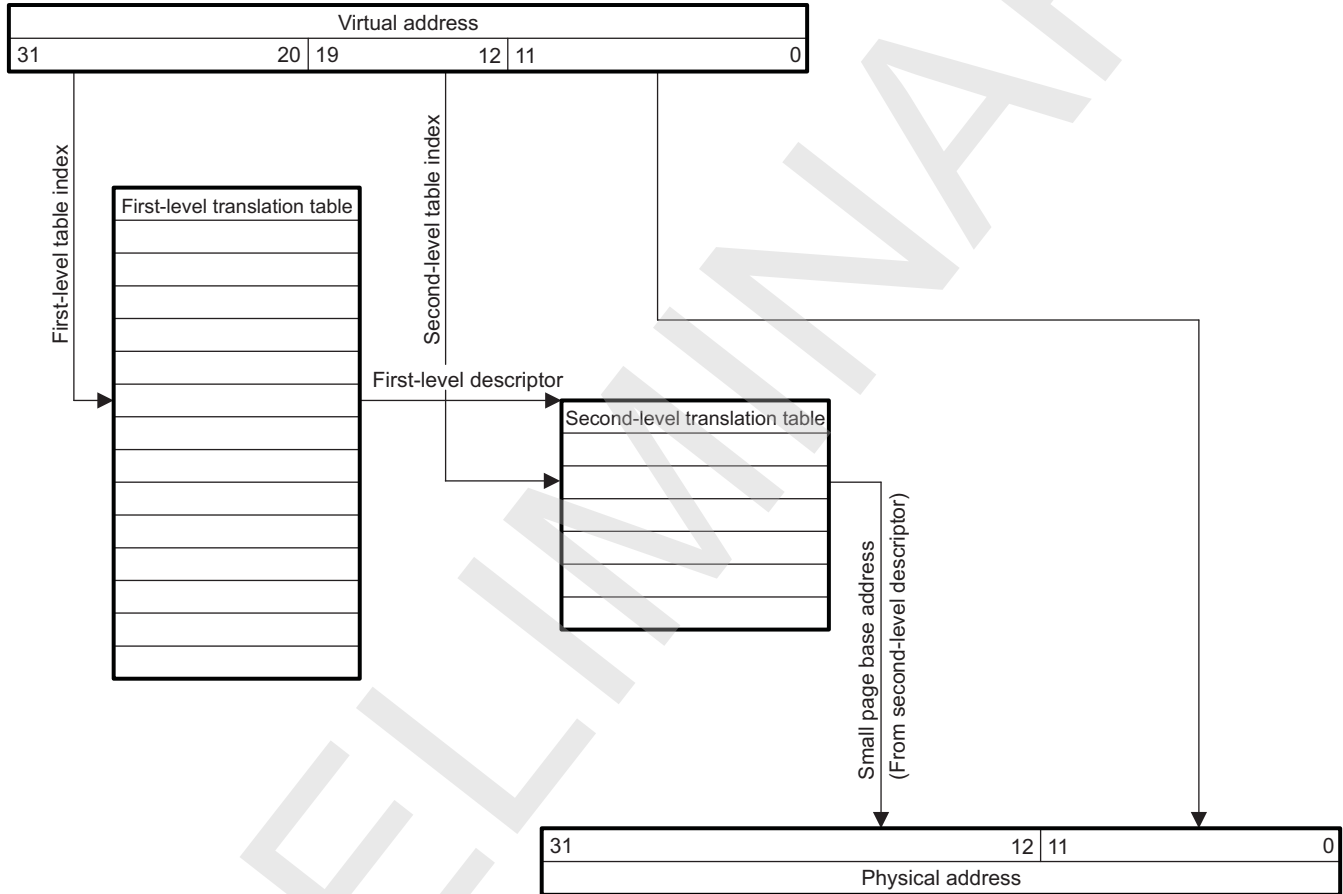

<sup>(1)</sup> See Table 20-42 for endianness limitations.

- M = Mixed region: 0 = Page-based endianness, 1 = Access-based endianness
- E = Endianness: 0 = Little-endian, 1 = Big-endian (endianness is locked on little endian)
- ES = Element Size: 00 = 8-bit, 01 = 16-bit, 10 = 32-bit, 11 = No endianness conversion
- X = Don't care

**20.3.1.2.3.2 Small Page Translation Summary**

Figure 20-12 summarizes the translation process for small pages.

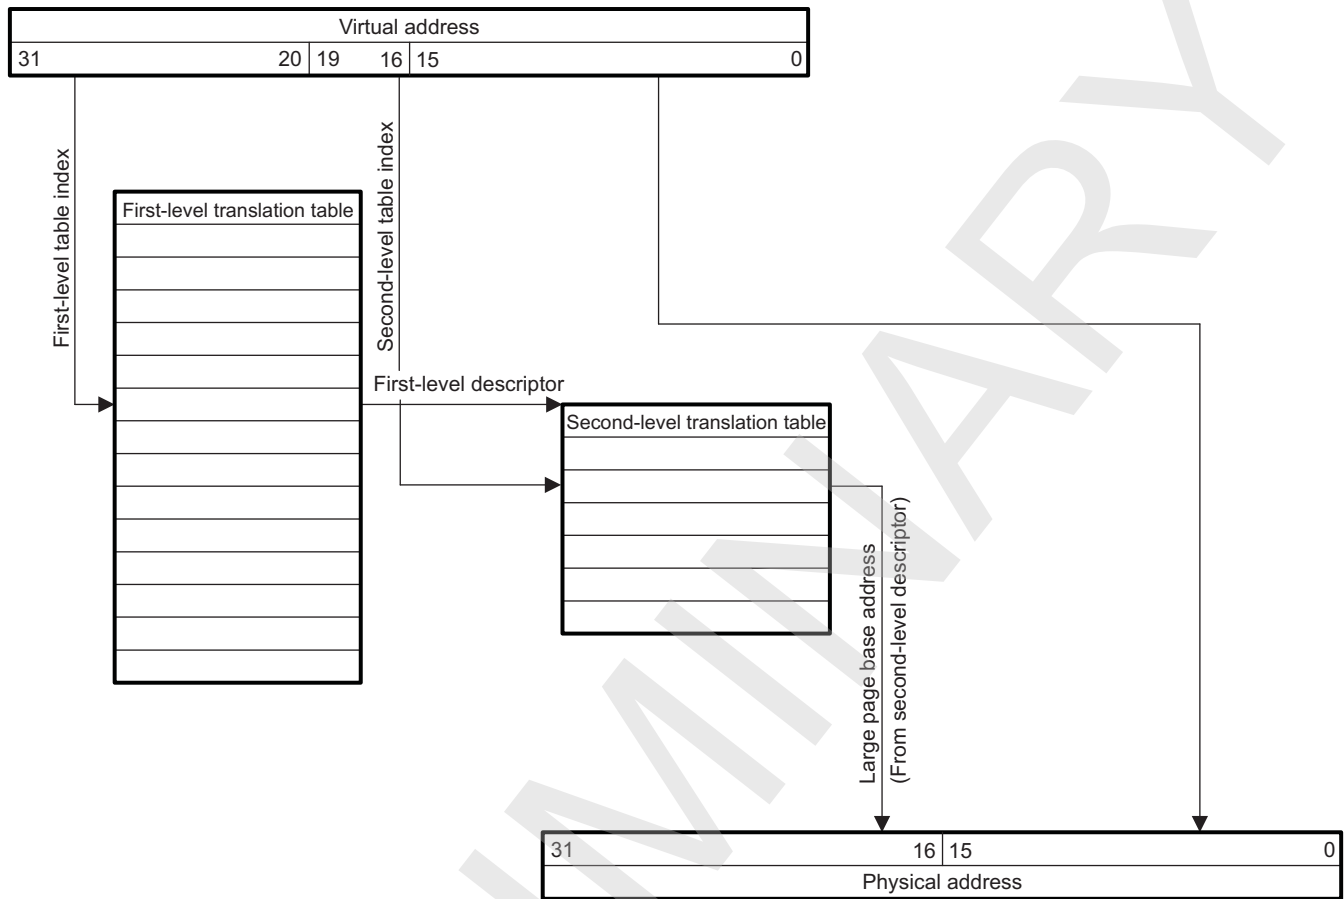

**Figure 20-12. Small Page Translation Summary**

mmu-014

**20.3.1.2.3.3 Large Page Translation Summary**

The translation of a large page is similar to the translation of a small page. The difference is that, for a large page, only bits 19 to 16 index into the second-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a large page. This is shown in Figure 20-13.

**Figure 20-13. Large Page Translation Summary**

mmu-015

### 20.3.1.3 Translation Lookaside Buffer

Translating virtual addresses to physical addresses is required for each memory access in systems using an MMU. To accelerate this translation process, a cache, or TLB, holds the result of recent translations.

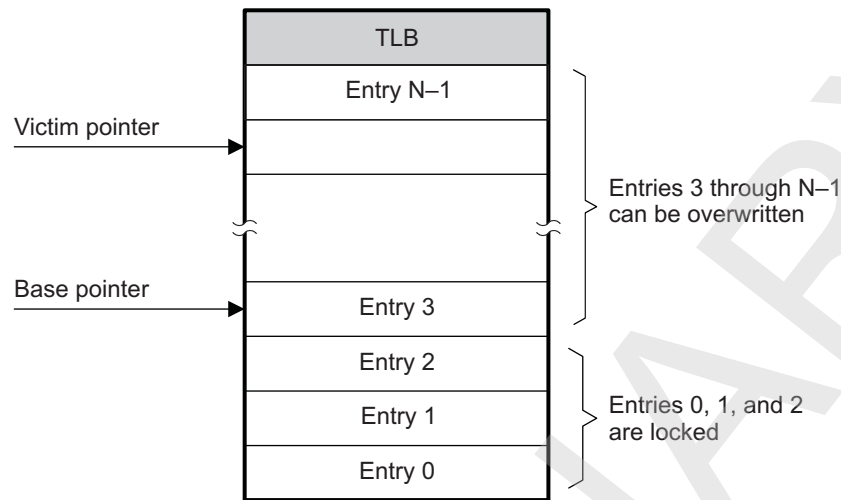

For every translation, the MMU internal logic first checks whether the requested translation is already cached in the TLB. If the translation is cached, this translation is used; otherwise the translation is retrieved from the translation tables and the TLB is updated. If the TLB is full, one of its entries must be replaced. This entry is selected on a random basis.

The first  $n$  TLB entries, where  $n < \text{Total Number } N \text{ of TLB Entries}$ , can be protected (locked) against being overwritten by setting the TLB base pointer to  $n$ . When this mechanism is used, only unprotected entries can be overwritten. The victim pointer indicates the next TLB entry to be written. Figure 20-14 shows an example of the TLB with  $N$  TLB entries (ranging from 0 to  $N-1$ ). The base pointer contains the value "3" protecting Entry 0, Entry 1, and Entry 2 and the victim pointer points to the next TLB entry to be updated.

**NOTE:** The last TLB entry (Entry  $N-1$ ) always remains unprotected.

Figure 20-14. TLB Entry Lock Mechanism

The table walking logic automatically writes the TLB entries. The entries can also be manually written, which is done typically to ensure that the translation of time-critical data accesses is already present in the TLB so that they execute as fast as possible. The entries must be locked to prevent them from being overwritten.

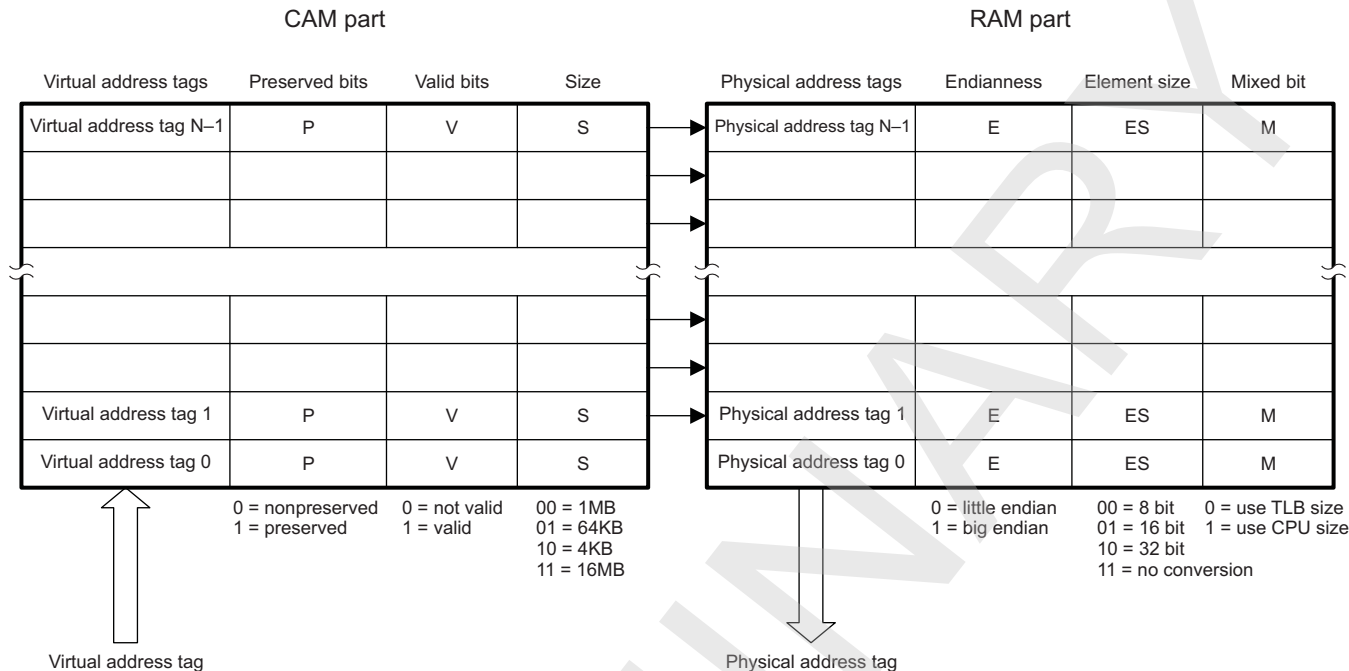

### 20.3.1.3.1 TLB Entry Format

TLB entries consist of two parts:

- The CAM part contains the virtual address tag used to determine if a virtual address translation is in the TLB. The TLB acts like a fully associative cache addressed by the virtual address tag. The CAM part also contains the section/page size, as well as the preserved and the valid parameters. See the [MMU\\_CAM](#) register table for more details.
- The RAM part contains the address translation that belongs to the virtual address tag as well as the endianness, element size, and mixed parameters described in [Section 20.3.1.2.2, First-Level Translation Table](#). See the [MMU\\_RAM](#) register table for more details.

The valid parameter specifies whether an entry is valid or not. The preserved parameter determines the behavior of an entry in the event of a TLB flush. If an entry is set as preserved, it is not deleted when a TLB is flushed, that is, when [MMU\\_GFLUSH\[0\] GLOBALFLUSH](#) is set to 1. Preserved entries must be deleted manually. [Section 20.3.1.2.2](#) describes the procedure to delete TLB entries.

[Figure 20-16](#) shows the TLB entry structure.

**Figure 20-15. TLB Entry Structure**

mmu-017

### 20.3.2 MMU Clock Configuration

There are two clock domains: The functional clock domain for the MMU, which is synchronous to the clock for the interconnect slave and master access ports; and the clock domain for the interconnect slave configuration port. As these clocks are matched, there is a single input clock with enables for each of the clock domains. If a clock domain should run at the same frequency as the input clock, that enable can be tied high.

Two clock enable signals exist, one to enable the interconnect data master and slave ports, and the other to enable the clock on the configuration L3 interconnect port. The clock signals are configured through the [MMU\\_SYSCONFIG](#) register. This is a system configuration register that controls the various parameters of the L3 interface.

### 20.3.3 MMU Software Reset

This section describes the software reset feature of the module. The MMU instances are reset together with their respective reset domains. See [Table 20-2](#) for information about the reset domains of the different MMU instances.

To perform a software reset, write 1 in the [MMU\\_SYSCONFIG\[1\]](#) SOFTRESET bit. The [MMU\\_SYSSTATUS\[0\]](#) RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the [MMU\\_SYSCONFIG\[1\]](#) SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before doing MMU operations. When an MMU instance is released from reset, its TLB is empty and the MMU is disabled.

### 20.3.4 MMU Power Management

As part of the device system-wide power management scheme, each MMU instance supports a communication protocol with the PRCM module that allows the PRCM module to request an MMU instance to enter a low-power state. When the MMU instance acknowledges a low-power mode request from the PRCM module, the clock to the instance is gated off at the PRCM clock generator. Because the clock is disabled at the source, the low-power mode offers lower power consumption than the internal clock gating method in the local power management.

[Table 20-6](#) describes the power-management features available for the MMU modules.

**NOTE:**

- For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**Table 20-6. MMU Local Power Management Features**

Feature	Register
Idle modes	MMU_SYSCONFIG[4:3] IDLEMODE
Clock activity	MMU_SYSCONFIG[9:8] CLOCKACTIVITY
Clock autogating	MMU_SYSCONFIG[0] AUTOIDLE

**NOTE:** The MMU\_SYSCONFIG[9:8] CLOCKACTIVITY bits are read only.

**20.3.5 MMU Interrupt Requests**

Table 20-7 lists the event flags and their masks that can cause module interrupts.

**Table 20-7. Events**

Event Flag	Event Mask	Synchrono- us	Sensitivit- y	Map to	Description
MMU_IRQSTATUS[4] MULTIHITFAULT	MMU_IRQENABLE[4] MULTIHITFAULT	Yes	Level	M3_IRQ_0	Error in the L2 MMU due to multiple matches in the TLB
MMU_IRQSTATUS[3] TABLEWALKFAULT	MMU_IRQENABLE[3] TABLEWALKFAULT	Yes	Level	M3_IRQ_0	Error in the L2 MMU due to error response received during a Table Walk
MMU_IRQSTATUS[2] EMUMISS	MMU_IRQENABLE[2] EMUMISS				For more information about emulation and debug features, see <a href="#">Chapter 28, On-Chip Debug Support</a> .
MMU_IRQSTATUS[1] TRANSLATIONFAULT	MMU_IRQENABLE[1] TRANSLATIONFAULT	Yes	Level	M3_IRQ_0	Error in the L2 MMU due to invalid descriptor in the translation tables (translation fault)
MMU_IRQSTATUS[0] TLBMISS	MMU_IRQENABLE[0] TLBMISS	Yes	Level	M3_IRQ_0	Error in L2 MMU due to unrecoverable TLB miss (hardware TWL disabled)

**20.3.6 MMU Error Handling**

Table 20-8 summarizes the intended operation for real and potential error conditions.

**Table 20-8. Error Handling**

Item	Condition	Action
1	Table-walk read has an error response.	Treat generally the same as a translation fault, but set the TableWalkFault interrupt status bit to aid in diagnosis
2	MMU is disabled during table-walk.	Not permitted; can result in loss of the current transaction but must not deadlock the MMU.  Avoid this condition by first disabling the table-walk logic and then polling the TWLRunning bit to ensure that no table walk is pending
3	MMU is disabled during an address translation.	Not permitted; can result in access to an unintended location, but must not deadlock MMU.  This condition should be avoided by ensuring that no accesses are pending.
4	TLB is accessed during an address translation or a table walk.	Reading permitted; write should be done with care to ensure that the TLB is self-consistent at all times that a translation can occur.

**Table 20-8. Error Handling (continued)**

Item	Condition	Action
5	TLB is flushed during address translation or a table walk.	Permitted; the flush is processed first, followed by the TWL update.
6	MMU is disabled while an interrupt is pending.	Not permitted; all pending interrupts should be processed before disabling the MMU.

L3 Interconnect configuration port: Accesses to undecoded register addresses must not give an error response.

To protect against changes to the address translation between a READEX and the corresponding write or during a burst the following configuration operations are protected against writes during these processes:

- TLB update
- Global flush
- Flush entry
- MMU disable

The protection is implemented by stalling the configuration interconnect transaction until the write can proceed safely.

## 20.4 MMU Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

### 20.4.1 Global Initialization

#### 20.4.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the MMU module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMU. For more information, see Section [Section 20.2, MMU Module Integration](#).

**Table 20-9. Global Initialization of Surrounding Modules**

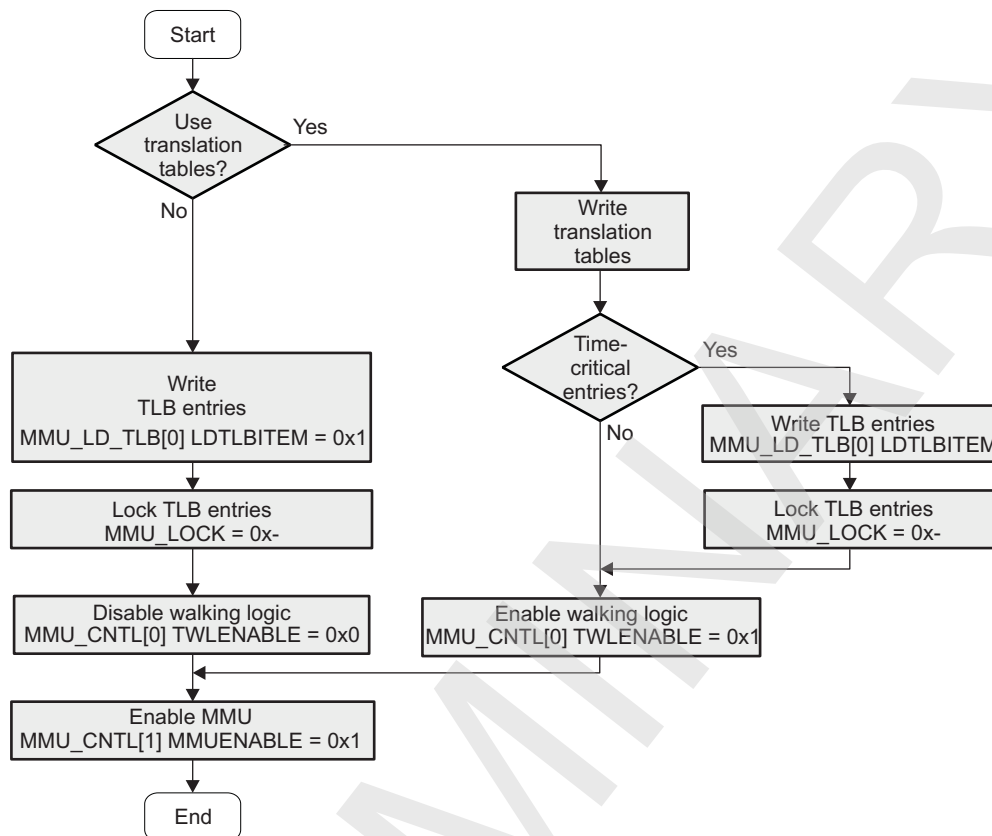

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
(optional) MPU INTC or DSP INTC or Cortex-M3 INTC	MPU, DSP, and Cortex-M3 interrupt controller configuration must be done to enable the interrupts from module.
Interconnect	For more information about the L3 interconnect configuration, see <a href="#">Section 13.2, L3 Interconnect</a> .

**NOTE:** If the interrupt-based communication mode is used, the MPU, DSP, and Cortex-M3 interrupt controllers configurations are required.

#### 20.4.1.2 MMU Global Initialization

##### 20.4.1.2.1 Main Sequence—MMU Global Initialization

[Figure 20-16](#) shows the procedure to initialize the MMU after a power-on or software reset.

**Figure 20-16. MMU Global Initialization**

mmu-018

**Table 20-10. Register Call Summary for Main Sequence—MMU Global Initialization**

Register Name	Register Name	Register Name
MMU_LD_TLB	MMU_LOCK	MMU_CNTL

#### 20.4.1.2.2 Subsequence—Configure a TLB entry

**Table 20-11. Configure a TLB Entry**

Step	Register / Bit Field / Programming Model	Value
Load the Virtual Address Tag	MMU_CAM[31:12] VATAG	0x-
Protect the TLB entry against flush	MMU_CAM[3] P	0x1
Validate the TLB entry	MMU_CAM[2] V	0x1
Define the page size	MMU_CAM[1:0] PAGESIZE	0x-

### 20.4.1.3 Operational Modes Configuration

#### 20.4.1.3.1 Main Sequence—Writing TLB Entries Statically

Writing TLB entries statically avoids the need to write translation tables in memory and is commonly used for relatively small address spaces. This method ensures that the translation of time-critical data accesses execute as fast as possible with entries already present in the TLB. These entries must be locked to prevent them from being overwritten.

**Table 20-12. MMU Writing TLB Entries Statically**

Step	Register/ Bit Field / Programming Model	Value
Execute software reset	MMU_SYSCONFIG[1] SOFTRESET	0x1
Wait for reset to complete	MMU_SYSSTATUS[0] RESETDONE	=0x1
Enable power saving via automatic interface clock gating	MMU_SYSCONFIG[0] AUTOIDLE	0x1
Configure TLB entries	See Table 20-11	
Load the physical Address of the page	MMU_RAM[31:12] PHYSICALADDRESS	0x-
Define the endianness of the page (little endian or big endian)	MMU_RAM[9] ENDIANNES	0x-
Select the element size	MMU_RAM[8:7] ELEMENTSIZE	0x-
Define mixed page attribute	MMU_RAM[6] MIXED	0x-
Specify the TLB entry you want to write	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Load the specified entry in the TLB	MMU_LD_TLB[0] LDTLBITEM	0x1
Enable multihit fault and TLB miss	MMU_IRQENABLE[4] MULTIHITFAULT	0x1
	MMU_IRQENABLE[0] TLBMISS	0x1
Enable memory translations	MMU_CNTL[1] MMUENABLE	0x1

#### 20.4.1.3.2 Main Sequence—Protecting TLB Entries

The first  $n$  TLB entries (with  $n <$  total number of TLB entries) can be protected from being overwritten with new translations. This is useful to ensure that certain commonly used or time-critical translations are always in the TLB and do not require retrieval using the table walking process.

**Table 20-13. Protecting TLB Entries**

Step	Register/Bit Field/Programming Model	Value
Locks the TLB entries	MMU_LOCK[14:10] BASEVALUE	0x-

#### 20.4.1.3.3 Main Sequence—Deleting TLB Entries

Two mechanisms exist to delete TLB entries. All unpreserved TLB entries, that is, TLB entries written with the preserved bit set to zero, can be deleted by invoking a TLB flush. The preserved bit should only be used on protected TLB entries, as it does not prevent replacement by the table walking logic.

**Table 20-14. Deleting TLB Entries**

Step	Register / Bit Field / Programming Model	Value
Flush all nonprotected TLB entries	MMU_GFLUSH[0] GLOBALFLUSH	0x1
Flush all TLB entries specified by the CAM register	MMU_FLUSH_ENTRY[0] FLUSHENTRY	0x1

#### 20.4.1.3.4 Main Sequence—Read TLB Entries

TLB entries can be read by the programmer to determine the TLB content at runtime.

**Table 20-15. Read TLB Entries**

Step	Register / Bit Field / Programming Model	Value
Set the current victim pointer	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Read RAM parts of the TLB entry	MMU_READ_RAM	
Read CAM parts of the TLB entry	MMU_READ_CAM	

## 20.5 MMU Register Manual

### 20.5.1 MMU Instance Summary

Table 20-16. MMU Instance Summary

Module Name	Base Address	Size
CORTEXM3_L2MMU	0x5508 2000	4KB
DSP MMU	0x4A06 6000	4KB

### 20.5.2 MMU Registers

#### 20.5.2.1 CORTEXM3\_L2MMU and DSP MMU Register Summary

Table 20-17. CORTEXM3\_L2MMU and DSP MMU Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	CORTEXM3_L2M MU Base Address	DSP MMU Base Address
MMU_REVISION	R	32	0x0000 0000	0x5508 2000	0x4A06 6000

PRELIMINARY

# Spinlock

This chapter describes the Spinlock module of the device.

Topic	Page
21.1 Spinlock Overview .....	3946
21.2 Spinlock Integration .....	3947
21.3 Spinlock Functional Description .....	3948
21.4 Spinlock Programming Guide .....	3951
21.5 Spinlock Register Manual .....	3954

## 21.1 Spinlock Overview

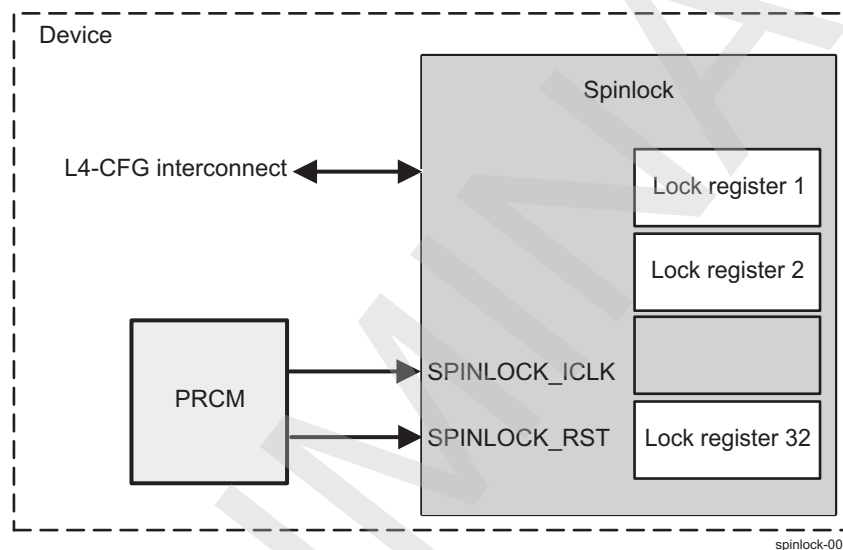

The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device:

- Cortex-A9 microprocessor unit (MPU) subsystem
- Digital signal processor (DSP) subsystem
- Cortex-M3 MPU subsystem

The Spinlock module implements 32 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 21-1 shows the Spinlock module.

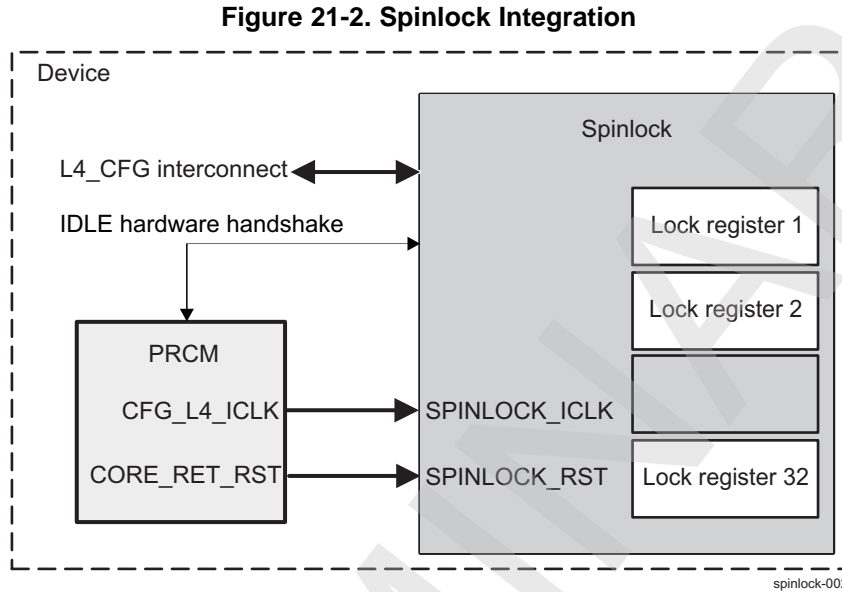

**Figure 21-1. Spinlock Module**

## 21.2 Spinlock Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 21-2 shows the Spinlock integration.

**NOTE:** For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module Level Clock Management, Chapter 3, Power, Reset, and Clock Management](#).

Table 21-1 and Table 21-2 summarize the integration of the module in the device.

**Table 21-1. Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
SPINLOCK	PD_CORE	L4_CFG

**Table 21-2. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SPINLOCK	SPINLOCK_ICLK	CFG_L4_ICLK	PRCM	Spinlock interface clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SPINLOCK	SPINLOCK_RST	CORE_RET_RST	PRCM	Spinlock hardware reset. This reset is asynchronously applied to the Spinlock internal registers.

The Spinlock module does not support any interrupt and DMA requests.

## 21.3 Spinlock Functional Description

### 21.3.1 Spinlock Software Reset

The Spinlock module can be reset by software through the `SPINLOCK_SYSCONFIG[1]` `SOFTRESET` bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. The `SPINLOCK_SYSTATUS[0]` `RESETDONE` bit can be polled to check the reset status (reading 1 indicates that reset sequence is done; reading 0 indicates that reset sequence is in progress). The software must ensure that the software reset completes before doing Spinlock operations.

### 21.3.2 Spinlock Power Management

Table 21-3 describes power-management features available to the Spinlock module.

**NOTE:**

- For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.4, Clock Domain Level Clock Management, Chapter 3, Power, Reset, and Clock Management](#).
- For descriptions of `EnaWakeUp`, `IdleMode`, `ClockActivity`, and `StandbyMode` features, see [Section 3.1.1.1.2, Module Level Clock Management, Chapter 3, Power, Reset, and Clock Management](#).

**Table 21-3. Local Power Management Features**

Feature	Registers	Description
Clock auto gating	<code>SPINLOCK_SYSCONFIG[0]</code> <code>AUTOGATING</code> bit	This bit indicates that the module uses an automatic internal interface clock gating strategy, based on interface activity.
Slave idle modes	<code>SPINLOCK_SYSCONFIG[4:3]</code> <code>SIDLEMODE</code> bit field	This bit field indicates that the module uses smart-idle mode.
Clock activity	<code>SPINLOCK_SYSCONFIG[8]</code> <code>CLOCKACTIVITY</code> bit	This bit indicates that the interface clock is not required by the module during idle mode and may be switched off.
Global wake-up enable	<code>SPINLOCK_SYSCONFIG[2]</code> <code>ENAWAKEUP</code> bit	This bit indicates that the wake-up generation feature (at module level) is disabled.

**NOTE:** All the local power management features are non-configurable (that is, their respective bits or bit fields are read-only).

**CAUTION**

The PRCM module has no hardware means of reading `CLOCKACTIVITY` settings. Thus, software must ensure consistent programming between the `CLOCKACTIVITY` bit and Spinlock clock PRCM control bits.

The Spinlock module is normally idle, except when processing a request from its slave interface port. The smart-idle mode acknowledges idle requests from the PRCM only when the module is prepared to go idle. The Spinlock module is always ready to go idle if it does not have any request that it is processing.

The Spinlock module uses retention flops to retain state including the Taken state of each lock register. This means that the module can be placed in retention at any time when it is not processing a request and it is known that the system will not need to access the module.

Software must ensure to only power off the Spinlock module when no locks would be lost. In general, the steps to powering down the Spinlock module are:

- Check that all masters which might use the Spinlock module are either:
  - (a) Already powered off, or
  - (b) Notified that Spinlock is not available and the notification is acknowledged.

- If desired, check that no locks are currently held in the Spinlock module. The status of each bank of 32 locks can be read from the [SPINLOCK\\_SYSTATUS](#) register. If any locks are held, they are orphaned because they are not held by any master that is still active. Alternatively, you may decide to wait a timeout period to allow any active master to clean up its locks before powering down.
- The Spinlock module can now be powered off by writing the appropriate status to the PRCM.

In the case of powering off the whole system, these steps are unnecessary.

### 21.3.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

1. The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
2. The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
3. The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

### 21.3.4 Spinlock Functional Operation

The Spinlock module supports 32 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the [SPINLOCK\\_LOCK\\_REG\\_i\[0\]](#) TAKEN bit. There are two states: Taken ([SPINLOCK\\_LOCK\\_REG\\_i\[0\]](#) TAKEN = 1) or Not Taken ([SPINLOCK\\_LOCK\\_REG\\_i\[0\]](#) TAKEN = 0).

When the status of lock *i* (where *i* = 0 to 31) is Not Taken (free), a read from the [SPINLOCK\\_LOCK\\_REG\\_i](#) register returns 0 and sets the lock to Taken (locked). When the status of lock *i* is Taken, a read returns 1 and does not change the state of the lock.

A write to the [SPINLOCK\\_LOCK\\_REG\\_i](#) register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

#### CAUTION

Only 32-bit reads and writes are supported.

Figure 21-3 shows the [SPINLOCK\\_LOCK\\_REG\\_i](#) register state diagram.

Figure 21-3. Lock Register State Diagram

**NOTE:**

- There is no support to ensure that a lock register is locked and unlocked by the same process. This must be ensured in software.
- There is no support to check that the same initiator that acquired the lock is the one that is freeing the lock.

## 21.4 Spinlock Programming Guide

### 21.4.1 Spinlock Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

#### 21.4.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

**Table 21-4. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	Spinlock interface clock must be enabled. For more information, see <a href="#">Section 3.6.14</a> , <a href="#">CD_L4_CFG Clock Domain</a> , <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Interconnect	For more information about the L4-CFG interconnect configuration, see <a href="#">Section 13.3, L4 Interconnects</a> .

#### 21.4.1.2 Basic Spinlock Operations

The main spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

##### 21.4.1.2.1 Spinlocks Clearing After a System Bug Recovery

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the [SPINLOCK\\_LOCK\\_REG\\_i](#) registers at system startup to insure that all locks are initialized to Not Taken.

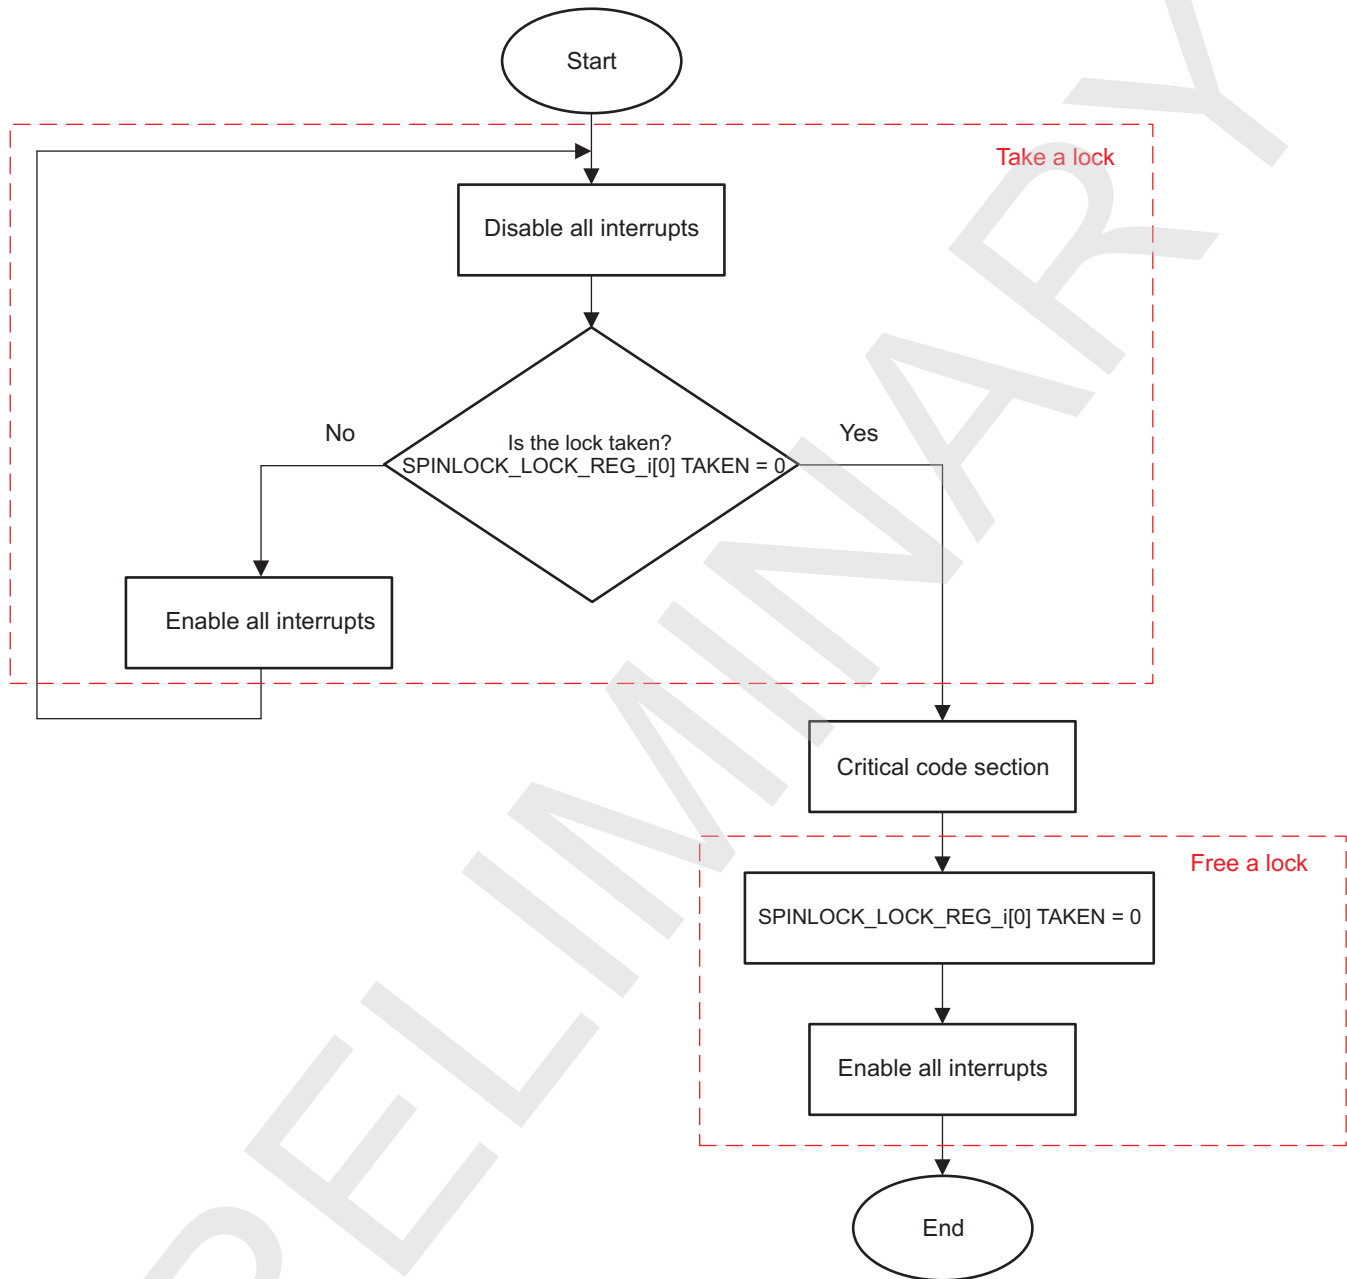

**Table 21-5. Spinlock System Bug Recovery**

Step	Register	Value
IF: <a href="#">SPINLOCK_SYSTATUS[0] IU0</a> == 1?	<a href="#">SPINLOCK_SYSTATUS[0] IU0</a>	
Free the 32 locks	<a href="#">SPINLOCK_LOCK_REG_i[0] TAKEN</a> (i=0 to 31)	0x0
END		

##### 21.4.1.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software should disable interrupts. Then it should read the [SPINLOCK\\_LOCK\\_REG\\_i\[0\] TAKEN](#) bit to attempt to obtain the lock. If it succeeds, it should proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition should be reattempted. To prevent unknown interrupt disabled time, interrupts should be re-enabled and then disabled before reattempting to acquire the lock. [Figure 21-4](#) shows the described above procedure.

# Timers

---

---

---

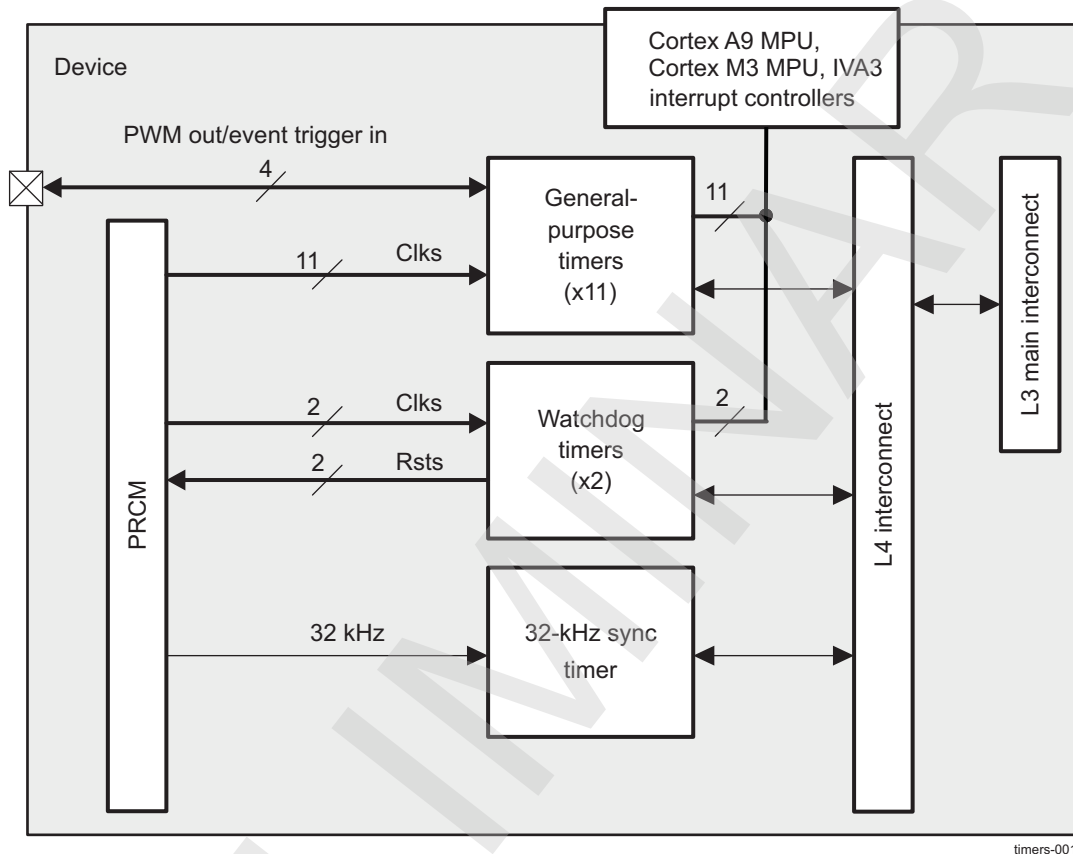

This chapter describes the timer modules for the device.

Topic	Page
22.1 Timers Overview .....	3960
22.2 General-Purpose Timers .....	3961
22.3 Watchdog Timers .....	4011
22.4 32-kHz Synchronized Timer .....	4037

## 22.1 Timers Overview

The device includes several types of timers used by the system software, including 11 general-purpose (GP) timers, two watchdog timers, and a 32-kHz synchronized timer (sync timer). Figure 22-1 is a high-level block diagram of the device timers.

**Figure 22-1. Timers**

The two watchdog timers are clocked with 32-kHz clocks. The 32-kHz sync timer, which is reset only at power up, provides the operating system (OS) with a stable timing source that stores the relative time since the last power cycle of the product. Finally, 11 GP timers, which are useful simply as basic timers, are included to generate time-stamp-based interrupts to the system software or to use as a source of pulse-width modulation (PWM) signals.

## 22.2 General-Purpose Timers

### 22.2.1 General-Purpose Timers Overview

The device has 11 general-purpose (GP) timers: GPTIMER1 through GPTIMER11.

Each timer can be clocked from either the system clock (12, 16.8, 19.2, 26, or 38.4 MHz) or the 32-kHz clock. The selection of clock source is made at the power, reset, and clock management (PRCM) module level. For more information, see [Section 3.6.3.1, PRM Clock Source](#).

GPTIMER1 has its GPT1\_EVENT\_CAPTURE pin tied to the 32-kHz clock and can be used to gauge the system clock input; it detects its frequency among 12, 16.8, 19.2, 26, or 38.4 MHz.

Each timer can provide an interrupt to the microprocessor unit (MPU) subsystem. In addition, GPTIMER5 through GPTIMER8 also have interrupts connected to the IVA3 subsystem.

GPTIMER1, GPTIMER2, and GPTIMER10 include specific functions to generate accurate tick interrupts to the operating system. GPTIMER8 through GPTIMER11 are connected to external pins by their PWM output or their event capture input pin (for external timer triggering). [Figure 22-2](#) is an overview of the GP timers.

Figure 22-2. GP Timers Overview

#### 22.2.1.1 GP Timer Features

The following are the main features of the GP timer controllers:

- L4 slave interface support:

- 32-bit data bus width
- 32-/16-bit access supported
- 8-bit access not supported
- 10-bit address bus width
- Burst mode not supported
- Write nonposted transaction mode supported
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source ( $2^n$  where  $n = [0:8]$ )
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated GP output signal for using the GPTi\_GPOCFG signal
- On-the-fly read/write register (while counting)
- 1-ms tick with 32,768-Hz functional clock generated (only GPTIMER1, GPTIMER2, and GPTIMER10)

## 22.2.2 GP Timer Environment

### 22.2.2.1 GP Timer External System Interface

Four of the 11 GP timers can send or receive stimulus to/from the external (off-chip) system. In the device; however, only GPTIMER8 through GPTIMER11 are configured to output a pulse-width modulation (PWM) pulse or receive an external event signal used as a trigger to capture the current timer count. GPTIMER1 is also configured to receive an event trigger input (GPT1\_EVENT\_CAPTURE) tied to the internal 32-kHz clock. This event signal gauges the system clock input; detecting its frequency among 12, 16.8, 19.2, 26, or 38.4 MHz.

Figure 22-3 shows the external system interface for the GP timers, and Table 22-1 describes the GP timer inputs and outputs.

**NOTE:** Software control must ensure that MUX mode is configured to select the dmtimerx\_pwm\_evt (where x = 8 to 11) signal on only one pad. Other pads on which the same signal is multiplexed must be configured in safe mode or non-dmtimer mode to avoid two different pads driving the same signal.

For more information about the configuration of the dmtimer8\_pwm\_evt through dmtimer11\_pwm\_evt I/O pads, see Section 18.4.8, *PAD Functional Multiplexing and Configuration*.

Figure 22-3. GP Timers External System Interface

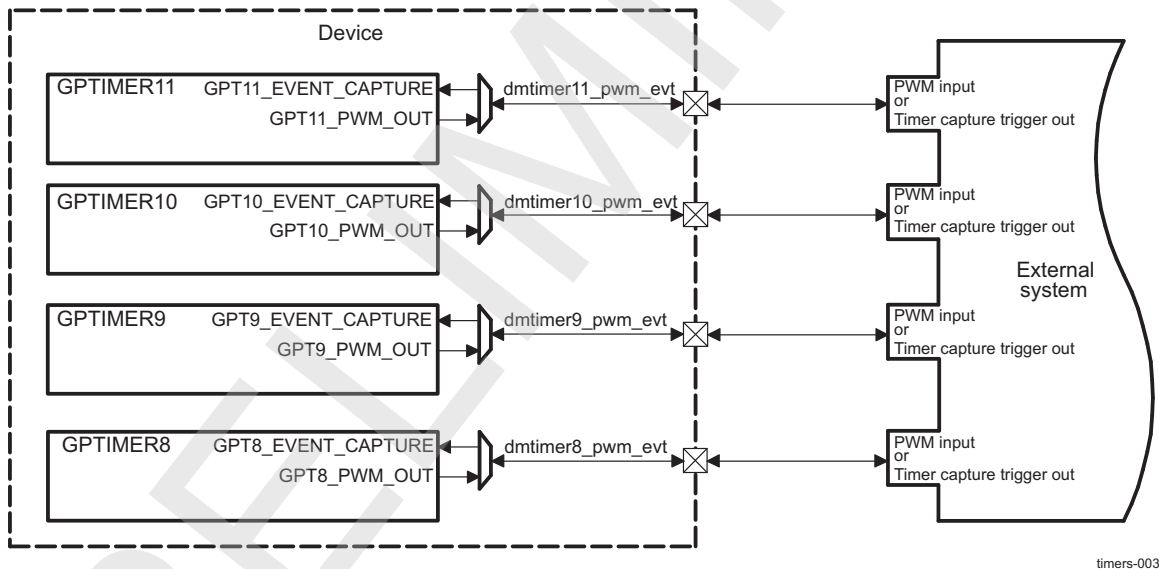

Table 22-1. Input/Output Description

Pin Name	Type <sup>(1)</sup>	Reset Value	Signal Name	Description
dmtimer8_pwm_evt	I/O	0	GPT8_EVENT_CAPTURE GPT8_PWM_OUT	GPTIMER8 trigger input/ PWM output
dmtimer9_pwm_evt	I/O	0	GPT9_EVENT_CAPTURE GPT9_PWM_OUT	GPTIMER9 trigger input/ PWM output
dmtimer10_pwm_evt	I/O	0	GPT10_EVENT_CAPTURE GPT10_PWM_OUT	GPTIMER10 trigger input/ PWM output
dmtimer11_pwm_evt	I/O	0	GPT11_EVENT_CAPTURE GPT11_PWM_OUT	GPTIMER11 trigger input/ PWM output

<sup>(1)</sup> When configured for that function; I = input, O = output

---

**NOTE:** The event trigger input (GPTi\_EVENT\_CAPTURE) for GPTIMER2 through GPTIMER7 is internally tied low, and the PWM output (GPTi\_PWM\_OUT) is not connected.

---

**NOTE:** For GPTIMER8 through GPTIMER11, the GPTi\_PORGPOCFG signal selects to connect the GPT pwm output or the GPT capture input to the dmtimerx\_pwm\_evt (where x = 8 to 11) pad at the top level. When the TCLR[14] GPO\_CFG bit = 0b1, the dmtimerx\_pwm\_evt functions as a capture input. When the TCLR[14] GPO\_CFG bit = 0b0, the dmtimerx\_pwm\_evt functions as a pwm output (GPO\_CFG = 0b0).

---

### 22.2.3 GP Timer Integration

Figure 22-4 shows the integration of the GP timer in the device.

Figure 22-4. GP Timer Integration

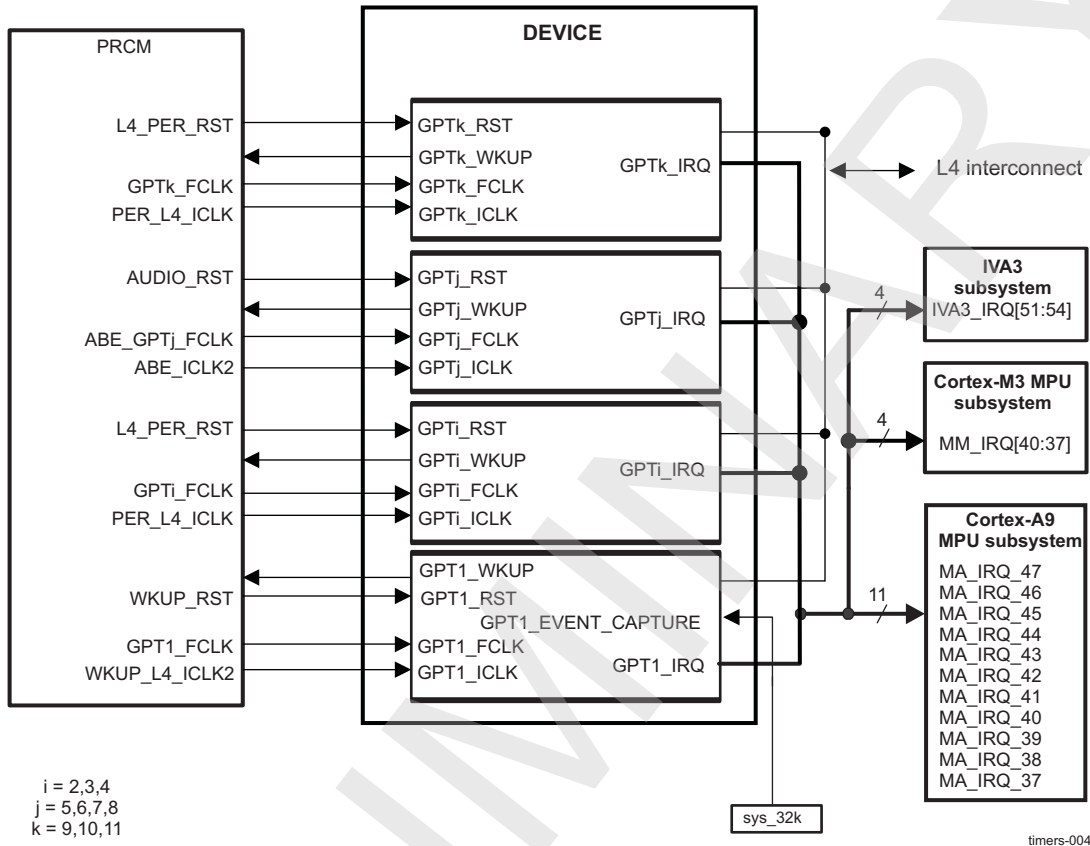

Table 22-2 through Table 22-4 summarize the integration of the module in the device.

Table 22-2. Integration Attributes

<b>No DMA Requests</b>				

**NOTE:** For the description of the interrupt source description, see [Section 22.2.4.5, GP Timer Interrupts](#).

## 22.2.4 GP Timer Functional Description

Each GP timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each GP timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line.

Each internal interrupt source can be independently enabled/disabled with a dedicated bit of the [GPT\\_TIER](#) register for the interrupt features, and a dedicated bit of the [GPT\\_TWER](#) register for the wake-up of GPTIMER1, GPTIMER2, and GPTIMER10. In addition, these timers have a mechanism implemented to generate an accurate tick interrupt.

For the other GP Timers, each internal interrupt source can be independently enabled/disabled through the [GPT\\_IRQENABLE\\_SET](#) and [GPT\\_IRQENABLE\\_CLR](#) register bit fields.

For each GP timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

Selection of the input clock source is done in the registers in the PRCM configuration (see [Section 22.2.1, GP Timer Overview](#)).

Each GP timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

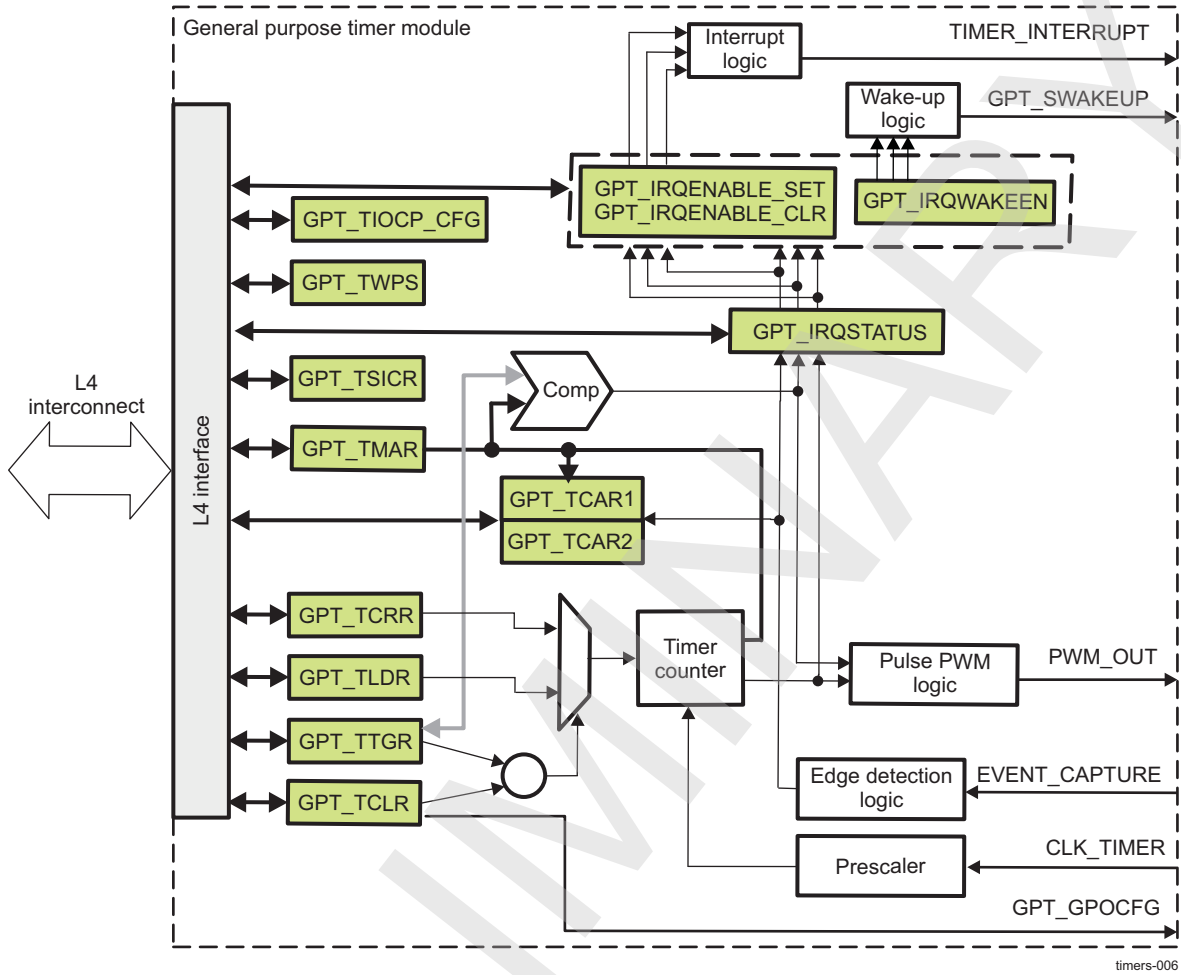

The capture and compare modes are disabled by default after core reset.

### 22.2.4.1 GP Timer Block Diagram

[Figure 22-5](#) is a block diagram of the common GP timers, and [Figure 22-6](#) is a block diagram of the GP timers with 1-ms tick generation module.

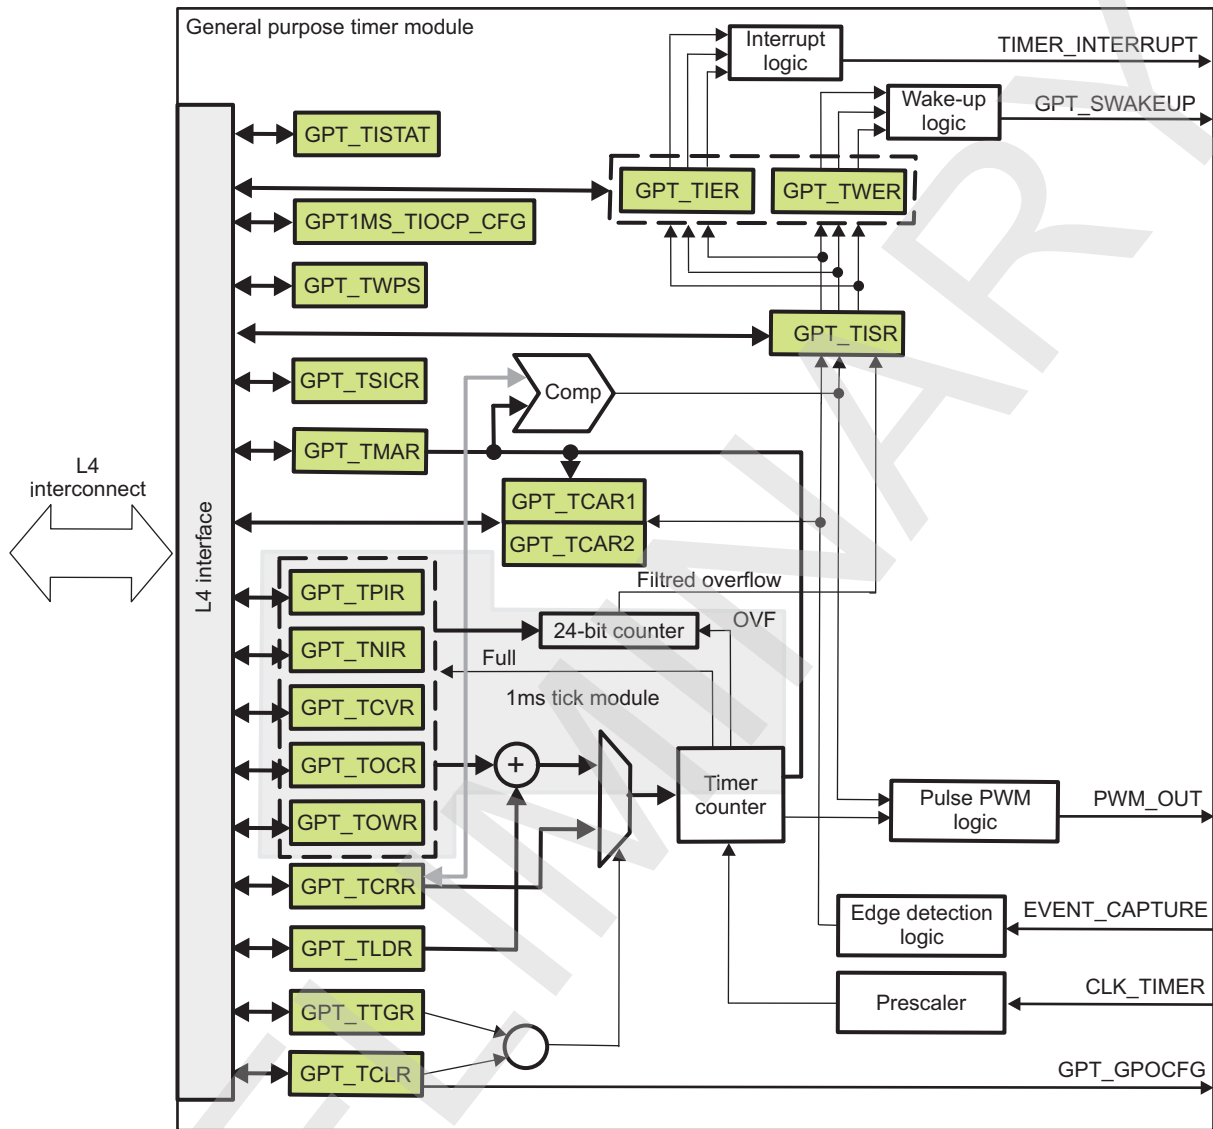

Figure 22-5. Block Diagram of GPTIMER3 Through GPTIMER9, and GPTIMER11

timers-006

Figure 22-6. Block Diagram of GPTIMER1, GPTIMER2, and GPTIMER10

timers-007

### 22.2.4.2 GPTIMER1, GPTIMER2, and GPTIMER10 Power Management

The GP timer modules have an internal bit, `GPT1MS_TIOCP_CFG[0]` AUTOIDLE, that is used to apply an internal interface clock gating strategy.

At the PRCM module level, when all conditions to shut off the PRCM module functional or interface output clocks are met (see [Section 3.1.1.1.4, Clock Domain Level Clock Management](#)), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the `GPT1MS_TIOCP_CFG[4:3]` IDLEMODE bit field.

[Table 22-7](#) lists the IDLEMODE settings and the related acknowledgment modes.

**Table 22-5. IDLEMODE Settings**

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Reserved	

When configured in smart-idle mode, the GP timer also offers an additional granularity on `GPTi_FCLK` and `GPTi_ICLK` gating. The `GPT1MS_TIOCP_CFG[9:8]` CLOCKACTIVITY bit field is used to determine which clock is shut down (`GPTi_FCLK`, `GPTi_ICLK`, neither, or both clocks).

The CLOCKACTIVITY setting is used internally to the GP timer to determine the part of the module on which the conditions to acknowledge the PRCM IDLE request are tested. For example, if `GPTi_FCLK` is not to be shut down on a PRCM IDLE request, the GP timer considers only `GPTi_ICLK` and associated pending activities before acknowledging the request.

Some GP timer features are associated with `GPTi_ICLK` and others are associated with `GPTi_FCLK`. Using the CLOCKACTIVITY setting along with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if the GP timer acknowledges an IDLE request.

[Table 22-6](#) lists the CLOCKACTIVITY settings and associated features.

**Table 22-6. CLOCKACTIVITY Settings**

CLOCKACTIVITY Value	GPTi_ICLK Effects	GPTi_FCLK Effects	Description	Associated Features
00	OFF	OFF	<code>GPTi_ICLK</code> and <code>GPTi_FCLK</code> are considered for generating the acknowledge. This setting also means <code>GPTi_FCLK</code> and <code>GPTi_ICLK</code> are likely to be shut down on PRCM IDLE request.	The idle acknowledge signal is asserted when there are no pending activities on the functional clock domain (improved latency in assertion of idle acknowledge). The wake-up capability of the GP timer is disabled.
01	ON	OFF	<code>GPTi_ICLK</code> is not shut down on PRCM IDLE request; only <code>GPTi_FCLK</code> is affected.	

**Table 22-6. CLOCKACTIVITY Settings (continued)**

CLOCKACTIVITY Value	GPTi_ICLK Effects	GPTi_FCLK Effects	Description	Associated Features
10	OFF	ON	GPTi_FCLK is not shut down on PRCM IDLE request; only GPTi_ICLK is affected.	The idle acknowledge signal is asserted when there are no pending activities on the interface clock domain, without evaluating the pending activities on the functional clock domain (the GP timer enters into sleep mode, and if a pending interrupt event is completed during idle mode, the wake-up signal is asserted). The wake-up signal is enabled.
11	ON	ON	None of the clocks are shut down. Therefore, the GP timer can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clocks.	

**CAUTION**

The PRCM module does not have any hardware means to read the CLOCKACTIVITY settings. The software must ensure consistent programming between the GP timer CLOCKACTIVITY and the PRCM module functional clock and interface clock control bits. If the GP timer is disabled in the CM\_FCLKEN and CM\_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the GP timer clocks. This can lead to unpredictable behavior.

**22.2.4.2.1 Wake-Up Capability**

If the `GPT1MS_TIOCP_CFG[4:3]` IDLEMODE bit field sets the smart-idle mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the `GPT1MS_TIOCP_CFG[2]` ENAWAKEUP bit enables the timer wake-up capability.

Figure 22-7 shows the wake-up request generation. For more information on the GP timer clock control, see Section 3.6, *Clock Management Functional Description* in Chapter 3, *Power, Reset and Clock Management*.

**Figure 22-7. Wake-Up Request Generation**

timers-005

For GPTIMER1, GPTIMER2, and GPTIMER10, the timer wake-up enable-register (**GPT\_TWVER**) allows masking the expected source of the wake-up event that generates a wake-up request. The **GPT\_TWVER** register is synchronously programmed with the interface clock before the PRCM module sends an idle mode request. The expected source of the wake-up event is an overflow (**GPT\_TCRR**), a timer match (the compare result of **GPT\_TCRR** and **GPT\_TMAR** matches the counter value), and a timer capture (detection of an external pulse transition of the correct polarity on the **GPT\_EVENT\_CAPTURE**).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (**GPT\_TISR**). The pending wake-up event is reset when the set status bit is overwritten with 1.

**NOTE:** The status bit must be reset to re-enter idle mode.

### 22.2.4.3 Power Management of Other GP Timers

At the PRCM module level, when all conditions to shut off the PRCM module functional or interface output clocks are met (see [Section 3.1.1.1.4, Clock Domain Level Clock Management](#)), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the **GPT\_TIOCP\_CFG[3:2]** IDLEMODE bit field.

[Table 22-7](#) lists the IDLEMODE settings and the related acknowledgment modes.

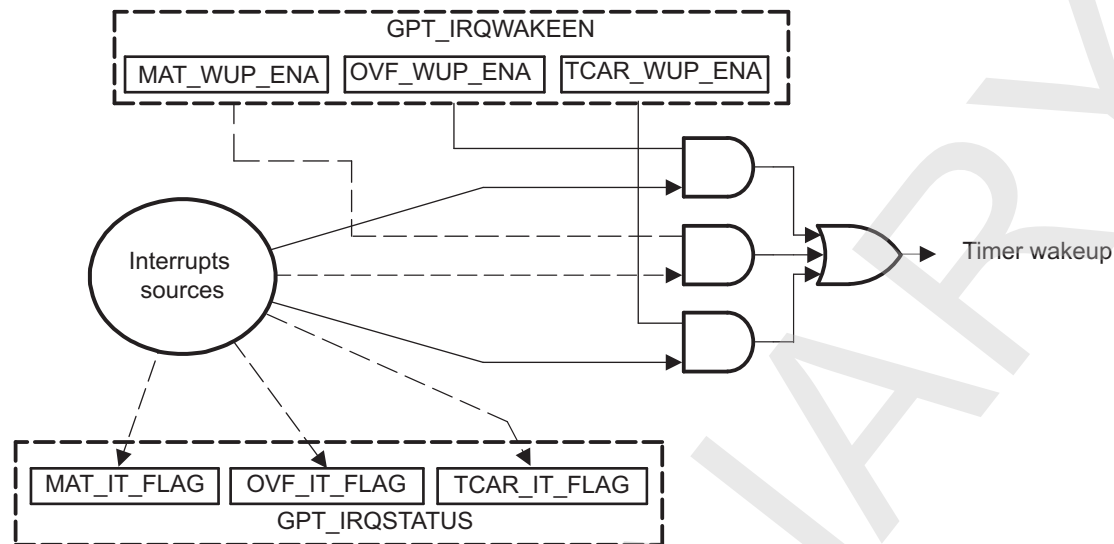

**Table 22-7. IDLEMODE Settings**

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Reserved	

#### 22.2.4.3.1 Wake-Up Capability

If the **GPT\_TIOCP\_CFG[3:2]** IDLEMODE bit field sets the smart-idle mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the **GPT\_IRQWAKEEN[2:0]** bit field enables the timer wake-up capability.

[Figure 22-8](#) shows the wake-up request generation. For more information on the GP timer clock control, see [Section 3.6, Clock Management Functional Description](#) in [Chapter 3, Power, Reset and Clock Management](#).

**Figure 22-8. Wake-Up Request Generation**

timers-014

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register ([GPT\\_IRQSTATUS](#)). The pending wake-up event is reset when the set status bit is overwritten with 1.

---

**NOTE:** The status bit must be reset to re-enter idle mode.

---

#### 22.2.4.4 Software Reset

Two bit fields can generate a software reset of the GP timer:

- [GPT1MS\\_TIOCP\\_CFG\[1\]](#) SOFTRESET for GPTIMER1, GPTIMER2, and GPTIMER10, and [GPT\\_TIOCP\\_CFG\[0\]](#) SOFTRESET for other timers
- [GPT\\_TSICR\[1\]](#) SFT for all timers

For both bits, all read accesses return 0.

The [GPT1MS\\_TIOCP\\_CFG\[1\]](#) SOFTRESET/[GPT\\_TIOCP\\_CFG\[0\]](#) SOFTRESET bit allows resetting the functional and interface domains. The [GPT\\_TSICR\[1\]](#) SFT bit allows resetting the functional part of the GP timer.

Before accessing or using the GP timer, the local host must ensure that both internal resets are released by reading the [GPT\\_TISTAT\[0\]](#) RESETDONE (for GPTIMER1, GPTIMER2, and GPTIMER10), or the [GPT\\_TIOCP\\_CFG\[0\]](#) SOFTRESET bit (for other timers). This bit monitors the internal reset status.

#### 22.2.4.5 GP Timer Interrupts

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled/disabled in the interrupt-enable register ([GPT\\_TIER](#) for GPTIMER1, GPTIMER2, and GPTIMER10), or, for other timers, enable in the interrupt-enable register ([GPT\\_IRQENABLE\\_SET](#)) and disable in the interrupt disable register ([GPT\\_IRQENABLE\\_CLR](#)). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register ([GPT\\_TISR](#) for GPTIMER1, GPTIMER2, and GPTIMER10, and [GPT\\_IRQSTATUS](#) for other timers).

#### 22.2.4.6 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register ([GPT\\_TCLR\[0\]](#) ST bit). The timer counter register ([GPT\\_TCRR](#)) can be loaded when stopped or on-the-fly (while counting). [GPT\\_TCRR](#) can be loaded directly by a [GPT\\_TCRR](#) write access with a new

timer value. The `GPT_TCR` register can also be loaded with the value held in the timer-load register `GPT_TLDR` by a trigger register (`GPT_TTGR`) write access. Loading of `GPT_TCR` is done regardless of the `GPT_TTGR` written value. The timer counter register `GPT_TCR` value can be read when stopped, or captured on-the-fly by a `GPT_TCR` read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the `GPT_TCLR[1]` AR bit set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

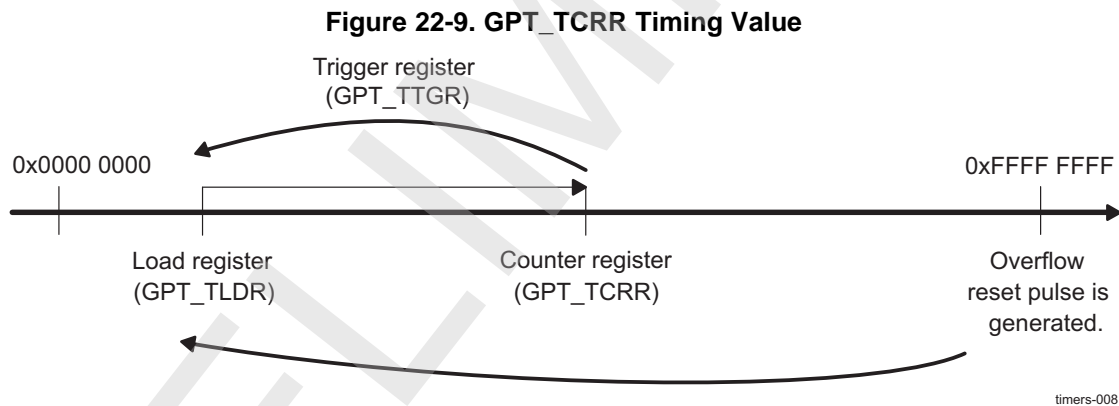

When the autoreload mode is enabled (the `GPT_TCLR[1]` AR bit set to 1), the `GPT_TCR` register is reloaded with the timer-load register (`GPT_TLDR`) value after a counting overflow occurs.

**CAUTION**

Do not put the overflow value (0xFFFF FFFF) in the `GPT_TLDR` register because it can lead to undesirable results.

An interrupt can be issued on overflow if the overflow interrupt-enable bit is set in the timer interrupt-enable register (`GPT_TIER[1]` OVF\_IT\_ENA bit set to 1 for GPTIMER1, GPTIMER2, and GPTIMER10, or `GPT_IRQENABLE_SET[1]` OVF\_IT\_FLAG bit set to 1 for other timers). A dedicated output pin (timer PWM) can be programmed in `GPT_TCLR[12]` through `GPT_TCLR[11:10]` (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The `GPT_TCLR[12]` PT bit selects pulse/toggle modulation (`GPT_TCLR[11:10]` TRG bit field selects trigger mode).

Figure 22-9 shows the `GPT_TCR` timing value.

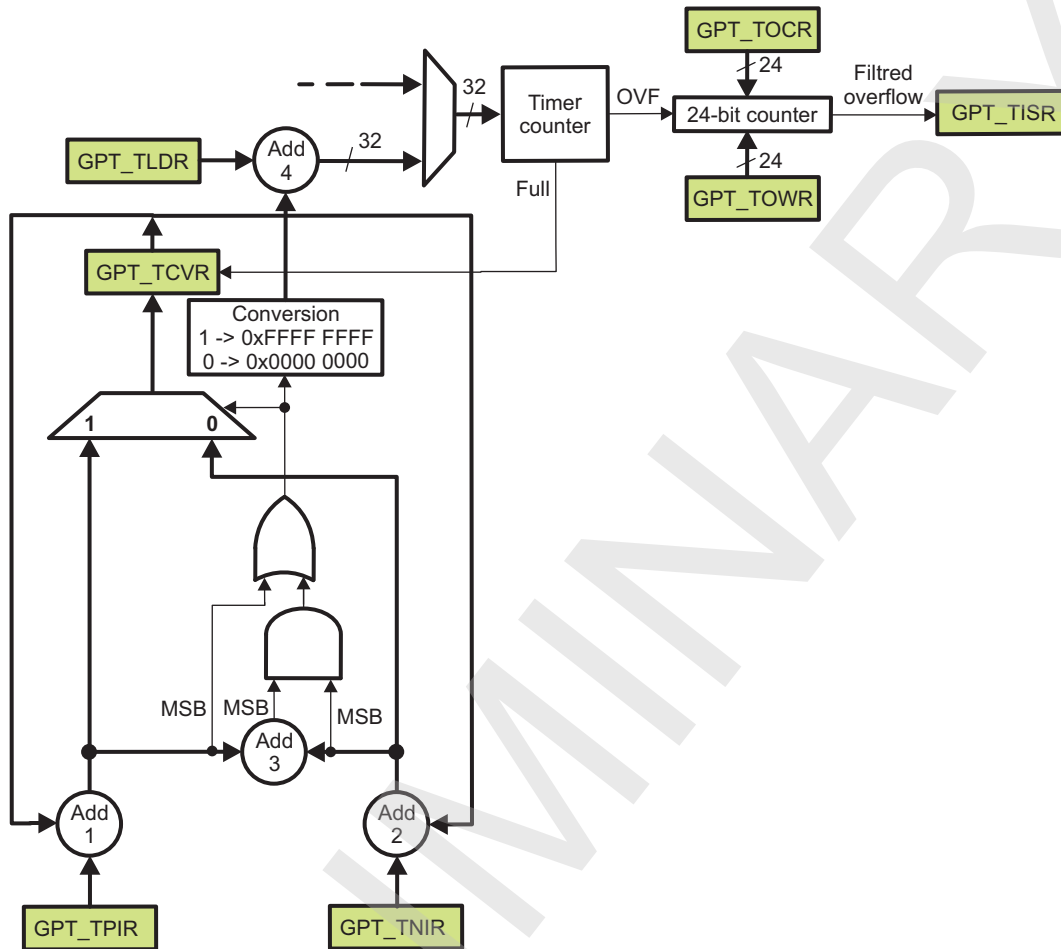

#### 22.2.4.6.1 1-ms Tick Generation (Only GPTIMER1, GPTIMER2, and GPTIMER10)

The interrupt period is not exactly 1 ms because the timer input clock is 32,768 Hz. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations from the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32,768 Hz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. See Figure 22-10.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (`GPT_TPIR[31:0]` POSITIVE\_INC\_VALUE bit field) and the timer negative increment register (`GPT_TNIR[31:0]` NEGATIVE\_INC\_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

Figure 22-10. Block Diagram of the 1-ms Tick Module

timers-009

The **GPT\_TPIR**, **GPT\_TNIR**, and **GPT\_TCRV** registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (**GPT\_TCRV[31:0]** **TIMER\_COUNTER** bit field) is the value of the **GPT\_TLDR[31:0]** **LOAD\_VALUE** bit field (period less than 1 ms) or the value of **GPT\_TLDR[31:0]** **LOAD\_VALUE** –1 (period greater than 1 ms).

Table 22-8 lists the value loaded in the **GPT\_TCRV** register according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value, MSB = 1: Negative value

Table 22-8. Value Loaded in **GPT\_TCRV** to Generate 1-ms Tick

Add1 MSB	Add2 MSB	Add3 MSB	Value of <b>GPT_TCRV</b> Register
0	0	0	<b>GPT_TLDR[31:0]</b> <b>LOAD_VALUE</b> bit field
0	0	1	<b>GPT_TLDR[31:0]</b> <b>LOAD_VALUE</b> bit field
0	1	0	<b>GPT_TLDR[31:0]</b> <b>LOAD_VALUE</b> bit field
0	1	1	<b>GPT_TLDR[31:0]</b> <b>LOAD_VALUE</b> –1
1	0	0	N/A
1	0	1	N/A
1	1	0	<b>GPT_TLDR[31:0]</b> <b>LOAD_VALUE</b> –1
1	1	1	<b>GPT_TLDR[31:0]</b> <b>LOAD_VALUE</b> –1

The values of the **GPT\_TPIR** and **GPT\_TNIR** registers are calculated using the following formula:

- Positive increment value =  $(\text{INTEGER}[F_{\text{clk}} * T_{\text{tick}}] + 1) * 1\text{e}6) - (F_{\text{clk}} * T_{\text{tick}} * 1\text{e}6)$
- Negative increment value =  $(\text{INTEGER}[F_{\text{clk}} * T_{\text{tick}}] * 1\text{e}6) - (F_{\text{clk}} * T_{\text{tick}} * 1\text{e}6)$

---

**NOTE:** Fclk clock frequency (kHz)

Ttick tick period (ms)

---

The timer overflow counter register (**GPT\_TOCR**) and the timer overflow wrapping register **GPT\_TOWR** are used to filter interrupts. When the timer overflows, it increments the 24-bit **GPT\_TOCR** register. When the 24-bit **GPT\_TOCR** register values match the value in the 24-bit **GPT\_TOWR** register and the timer overflow is asserted, the **GPT\_TOCR** register is reset and an interrupt is generated to the **GPT\_TISR** register.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of GPTIMER1, GPTIMER2, and GPTIMER10 remain unchanged.

For 1-ms tick with a 32,768-Hz clock:

- **GPT\_TPIR**[31:0] POSITIVE\_INC\_VALUE = 232000
- **GPT\_TNIR**[31:0] NEGATIVE\_INC\_VALUE = -768000
- **GPT\_TLDR**[31:0] LOAD\_VALUE = 0xFFFF FFE0

---

**NOTE:** Any value of the tick period can be generated with the appropriate value of the **GPT\_TPIR**, **GPT\_TNIR**, and **GPT\_TLDR** registers.

By default, the **GPT\_TPIR**, **GPT\_TNIR**, **GPT\_TCVR**, **GPT\_TOCR**, and **GPT\_TOWR** registers and the associated logic are in reset mode (all 0s) and have no action on the programming model.

---

#### 22.2.4.7 Capture Mode Functionality

When a transition is detected on the module input pin (**EVENT\_CAPTURE**), the timer value in the **GPT\_TCRR** register can be captured and saved in the **GPT\_TCAR1** or **TCAR2** register function of the mode selected in the **GPT\_TCLR**[13] **CAPT\_MODE** bit. The edge detection circuitry monitors transitions on the input pin (**EVENT\_CAPTURE**).

The rising edge, falling edge, or both, can be selected in the **GPT\_TCLR**[9:8] **TCM** bit field to trigger the timer counter capture. The module sets the **GPT\_TISR**[2] **TCAR\_IT\_FLAG** bit for GPTIMER1, GPTIMER2, or GPTIMER10, and the **GPT\_IRQSTATUS**[2] **TCAR\_IT\_FLAG** bit for other timers, when an active edge is detected, and at the same time, the counter value **GPT\_TCRR** is stored in timer capture register **GPT\_TCAR1** or **GPT\_TCAR2**, as follows:

- If the **GPT\_TCLR**[13] **CAPT\_MODE** bit is 0, on the first enabled capture event, the value of the counter register is saved in the **GPT\_TCAR1** register, and all the next events are ignored (no update on the **GPT\_TCAR1** register and no interrupt triggering) until the detection logic is reset or the **GPT\_TISR**[2] **TCAR\_IT\_FLAG** bit (or **GPT\_IRQSTATUS**[2] **TCAR\_IT\_FLAG**, depending on the timer) is cleared by writing 1 to it.
- If the **GPT\_TCLR**[13] **CAPT\_MODE** bit is 1, on the first enabled capture event, the value of the counter register is saved in the **GPT\_TCAR1** register, and on the second enabled capture event, the value of the counter register is saved in the **GPT\_TCAR2** register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on **GPT\_TCAR1**/**GPT\_TCAR2** and no interrupt triggering) until the detection logic is reset or **GPT\_TISR**[2] **TCAR\_IT\_FLAG** bit (or **GPT\_IRQSTATUS**[2] **TCAR\_IT\_FLAG**, depending on the timer) is cleared by writing 1 to it. This mechanism is useful for period calculation of a clock, if that clock is connected to the **EVENT\_CAPTURE** input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The **GPT\_TISR**[2] **TCAR\_IT\_FLAG** bit or the **GPT\_IRQSTATUS**[2] **TCAR\_IT\_FLAG** (previously 1) is cleared by writing 1 to it or when the edge detection mode bits (the **GPT\_TCLR**[9:8] **TCM** bit field) are

changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (EVENT\_CAPTURE). A negative or positive pulse input can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt-enable bit is set in the `GPT_TIER[2]` `TCAR_IT_ENA` bit (for GPTIMER1, GPTIMER2, or GPTIMER10), or in the `GPT_IRQENABLE_SET[2]` `TCAR_EN_FLAG` bit (for other timers). See the examples in [Figure 22-11](#) and [Figure 22-12](#).

In [Figure 22-11](#), the `GPT_TCLR[9:8]` TCM bit field value is 0b01, and `GPT_TCLR[13]` `CAPT_MODE` bit is 0. Only the rising edge of `EVENT_CAPTURE` triggers a capture in the `GPT_TCAR1` and `GPT_TCAR2` registers, and only the `GPT_TCAR1` register updates.

**Figure 22-11. Capture Wave Example for `GPT_TCLR[13]` `CAPT_MODE` = 0**

In [Figure 22-12](#), the value of the `GPT_TCLR[9:8]` TCM bit field is 0b01, and the `GPT_TCLR[13]` `CAPT_MODE` bit is 1. Only the rising edge of `EVENT_CAPTURE` triggers a capture in the `GPT_TCAR1` register on the first enabled event, and the `GPT_TCAR2` register updates on the second enabled event.

**Figure 22-12. Capture Wave Example for `GPT_TCLR[13]` `CAPT_MODE` = 1**

#### 22.2.4.8 Compare Mode Functionality

When compare enable-register `GPT_TCLR[6]` `CE` bit is set to 1, the timer value (`GPT_TCR[31:0]`)

TIMER\_COUNTER bit field) is continuously compared to the value held in the timer match register (GPT\_TMAR). The GPT\_TMAR[31:0] COMPARE\_VALUE bit field value can be loaded at any time (timer counting or stopped). When the GPT\_TCRR and the GPT\_TMAR values match, an interrupt is issued, if the GPT\_TIER[0] MAT\_IT\_ENA (for GPTIMER1, GPTIMER2, and GPTIMER10), or GPT\_IRQSTATUS\_SET[0] MAT\_EN\_FLAG bit (for other timers) is set.

The right programming way is to write a compare value to the GPT\_TMAR register before setting the GPT\_TCLR[6] CE bit to prevent any unwanted interrupts due to a reset value matching effect.

The dedicated output pin (timer PWM) can be programmed in the GPT\_TCLR[12] PT bit through the GPT\_TCLR[11:10] TRG bit field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

### 22.2.4.9 Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the GPT\_TCLR[5] PRE bit is set. The GPT\_TCLR[4:2] PTV bit field sets the second prescaler ratio. The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 22-9 lists the prescaler/timer reload values versus contexts.

**Table 22-9. Prescaler/Timer Reload Values Versus Contexts**

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	GPT_TLDR[31:0]
GPT_TCRR write	Reset	GPT_TCRR[31:0]
GPT_TTGR write	Reset	GPT_TLDR[31:0]
Stop	Reset	Frozen

### 22.2.4.10 Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM output pin can be configured to toggle on an event. The GPT\_TCLR[11:10] TRG bit field determines on which register value the PWM pin toggles. Either overflow alone or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

**CAUTION**

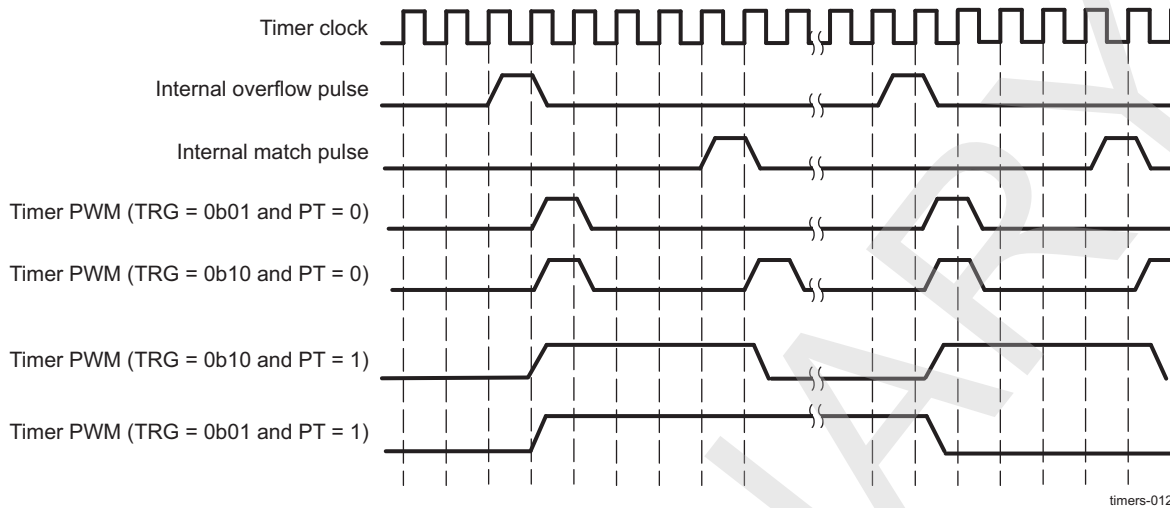

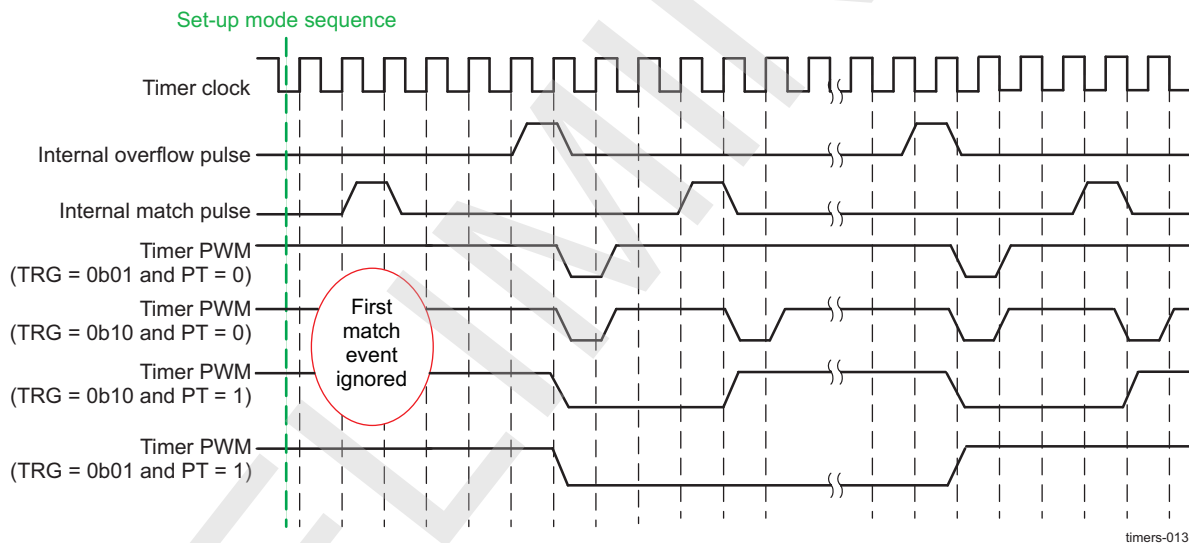

In toggle mode, when GPT\_TCLR[11:10] TRG = 0x2 (overflow and match), the first event that toggles the PWM line is an overflow event. If a match event occurs first; it does not toggle the PWM line (see Figure 22-14).

The GPT\_TCLR[7] SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the GPT\_TCLR[11:10] TRG bit field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In Figure 22-13, the internal overflow pulse is set each time (0xFFFF FFFF - GPT\_TLDR[31:0] LOAD\_VALUE + 1) the value is reached, and the internal match pulse is set when the counter reaches the GPT\_TMAR register value. Depending on the value of the GPT\_TCLR[12] PT bit and GPT\_TCLR[11:10] TRG bit field, the timer provides pulse or PWM event on the output pin (timer PWM).

The GPT\_TLDR and GPT\_TMAR registers must keep values below the overflow value (0xFFFF FFFF) by at least two units. In case the PWM trigger events are both overflow and match, the difference between the values kept in the GPT\_TMAR register and the value in the GPT\_TLDR register must be at least two units. When match event is used, the compare mode GPT\_TCLR[6] CE bit must be set.

In Figure 22-13, the GPT\_TCLR[7] SCPWM bit is set to 0. In Figure 22-14, the GPT\_TCLR[7] SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (GPT\_TCLR[7] SCPWM bit).

**Figure 22-13. Timing Diagram of PWM With GPT\_TCLR[7] SCPWM Bit = 0****Figure 22-14. Timing Diagram of PWM With GPT\_TCLR[7] SCPWM Bit = 1**

### 22.2.4.11 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (the [GPT\\_TCLR\[5\] PRE](#) bit and the [GPT\\_TCLR\[4:2\] PTV](#) bit field)
- Value loaded into the timer-load register ([GPT\\_TLDR](#))

[Table 22-10](#) lists the prescaler clock ratio values.

**Table 22-10. Prescaler Clock Ratio Values**

<a href="#">GPT_TCLR[5] PRE</a>	<a href="#">GPT_TCLR[4:2] PTV</a>	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32

**Table 22-10. Prescaler Clock Ratio Values (continued)**

GPT_TCLR[5] PRE	GPT_TCLR[4:2] PTV	Divisor (PS)
1	5	64
1	6	128
1	7	256

Thus, the timer overflow rate is expressed as:

$$OVF\_Rate = (0xFFFF FFFF - GPT\_TLDR + 1) * (\text{timer-functional clock period}) * PS$$

With (timer-functional clock period) = 1/(timer-functional clock frequency) and PS = 2<sup>(PTV + 1)</sup> if prescaler is enabled, or PS = 1 if prescaler is disabled.

**CAUTION**

Internal resynchronization causes any write to the GPT\_TCLR[1] ST bit to have some latency before the register is updated:

2.5 \* functional clock cycles write\_GPT\_TCLR\_latency 3.5 \* functional clock cycles

Remember to consider this latency whenever the timer must be started or stopped by a software change to the GPT\_TCLR[1] ST bit.

**CAUTION**

- In the non-PWM mode, GPT\_TLDR must be maintained at less than or equal to 0xFFFF FFFE.
- In the PWM mode, GPT\_TLDR must be maintained at less than or equal to 0xFFFF FFFD.

For example, with a timer clock input of 32 kHz and the GPT\_TCLR[5] PRE bit set to 0, the timer output period is as listed in Table 22-11.

**Table 22-11. Value and Corresponding Interrupt Period**

GPT_TLDR[31:0] LOAD_VALUE	Interrupt Period
0x0000 0000	39 h
0xFFFF 0000	2.1 s
0xFFFF FFF0	524 μs
0xFFFF FFFE	65.5 μs

**22.2.4.12 Timer Under Emulation**

During emulation mode, the timer continues to run according to the value of the GPT1MS\_TIOCP\_CFG[5]/GPT\_TIOCP\_CFG[1] EMUFREE bit.

If the GPT1MS\_TIOCP\_CFG[5]/GPT\_TIOCP\_CFG[1] EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the GPT1MS\_TIOCP\_CFG[5]/GPT\_TIOCP\_CFG[1] EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (dmtimer\_i\_pwm\_evt, with i=[8:11]) is internally synchronized on two timer-clock rising edges.

**22.2.4.13 Accessing GP Timer Registers**

All accesses are nonposted until software reconfiguration. All registers are 32 bits wide, accessible through the L4 interface with 16-bit or 32-bit access (read/write).

Any 16-bit write access must be least-significant bit (LSB) first, and the second write access must be most-significant bit (MSB) first. Write operations to the following GP timer registers can skip the MSB access if it is not necessary to update the 16 MSBs of the register:

- GPT\_TIDR
- GPT\_TIOCP\_CFG
- GPT1MS\_TIOCP\_CFG
- GPT\_IRQSTATUS\_RAW
- GPT\_IRQSTATUS
- GPT\_IRQENABLE\_SET
- GPT\_IRQENABLE\_CLR
- GPT\_IRQWAKEEN
- GPT\_TISR
- GPT\_TIER
- GPT\_TWER
- GPT\_TSICR

Write operations to the following functional registers must be complete (the MSB must be written even if the MSB data is not used):

- GPT\_TCLR
- GPT\_TCRR
- GPT\_TLDR
- GPT\_TTGR
- GPT\_TMAR
- GPT\_TPIR
- GPT\_TNIR
- GPT\_TCVR
- GPT\_TOCR
- GPT\_TOWR

The following L4 synchronous registers are not affected by the posted/nonposted mode selection; the write/read operation is effective and acknowledged (command accepted) after one L4 clock cycle from command assertion:

- GPT\_TIDR
- GPT\_TIOCP\_CFG
- GPT1MS\_TIOCP\_CFG
- GPT\_TISTAT
- GPT\_IRQSTATUS
- GPT\_IRQSTATUS\_RAW
- GPT\_IRQENABLE\_SET
- GPT\_IRQENABLE\_CLR
- GPT\_IRQWAKEEN
- GPT\_TWPS
- GPT\_TSICR

#### 22.2.4.13.1 Writing to Timer Registers

The host uses the L4 interface to write to the following registers synchronously with the timer interface clock:

- GPT\_TLDR
- GPT\_TCRR
- GPT\_TCLR
- GPT\_TIOCP\_CFG

- [GPT1MS\\_TIOCP\\_CFG](#)
- [GPT\\_IRQSTATUS](#)
- [GPT\\_IRQENABLE\\_SET](#)
- [GPT\\_IRQENABLE\\_CLR](#)
- [GPT\\_IRQWAKEEN](#)
- [GPT\\_TTGR](#)
- [GPT\\_TSICR](#)
- [GPT\\_TMAR](#)

GPTIMER1, GPTIMER2, and GPTIMER10 also have the following registers:

- [GPT\\_TPIR](#)
- [GPT\\_TNIR](#)
- [GPT\\_TCVR](#)
- [GPT\\_TOCR](#)
- [GPT\\_TOWR](#)
- [GPT\\_TIER](#)
- [GPT\\_TISR](#)
- [GPT\\_TWER](#)

In 16-bit access mode, the 16 LSBs must be written before writing to the 16 MSBs.

#### **22.2.4.13.1.1 Write Posting Synchronization Mode**

This mode is used if the [GPT\\_TSICR](#)[2] POSTED bit is set to 1.

This mode uses a posted write scheme to update any internal register ([GPT\\_TCLR](#), [GPT\\_TCRR](#), [GPT\\_TLDR](#), [GPT\\_TTGR](#), [GPT\\_TMAR](#), and [GPT\\_TPIR](#), [GPT\\_TNIR](#), [GPT\\_TCVR](#), [GPT\\_TOCR](#), and [GPT\\_TOWR](#) for GPTIMER1, GPTIMER2, and GPTIMER10). Therefore, the write transaction is immediately acknowledged on the L4 interface, although the effective write operation occurs later due to a resynchronization in the timer clock domain. The advantage is that neither the interconnect nor the device that requested the write transaction are stalled.

For each register, a status bit is provided in the timer write-posted status register [GPT\\_TWPS](#). In this mode, it is mandatory that the software checks this status bit prior to any write access. In case a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the timer counter register value synchronously with the L4 clock. Consequently, any read access to the timer counter register [GPT\\_TCRR](#) does not add any resynchronization latency; the current value is always available.

---

**NOTE:** Since the overflow IRQ is generated, when the TCRR value reaches 0xFFFF FFFF, and not when it changes its value to the value after overflow, one must wait a delay of (1 \* PS \* timer-functional clock period) before any read access to the timer counter register [GPT\\_TCRR](#) to ensure a correct reading of its content.

---

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

The drawback of this automatic update mechanism is that it assumes a given relationship between the timer interface frequency and the timer clock frequency.

Functional frequency range:  $\text{freq}(\text{timer clock}) < \text{freq}(\text{L4 interface clock})/4$ .

### 22.2.4.13.1.2 Write Nonposting Synchronization Mode

This mode is used if the `GPT_TSICR[2]` POSTED bit is set to 0. It uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the L4 interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that both the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the L4 interface frequency and the timer clock frequency.

### 22.2.4.13.2 Reading From Timer Counter Registers

In 16-bit access mode, reading the 16 LSBs from the timer counter registers (`GPT_TCRR`, `GPT_TCAR1`, and `GPT_TCAR2`) captures the current timer counter value. This must be followed by reading the 16 MSBs.

IVA3 subsystem 16-bit accesses can be interleaved with MPU subsystem 32-bit accesses.

---

**NOTE:** LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

---

## 22.2.5 GP Timer Low-Level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

### 22.2.5.1 Global Initialization

#### 22.2.5.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the GP timer module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the GP timer. For more information, see [Section 22.2.3 GP Timers Integration](#) and [Section 22.2.2 GP Timers Environment](#).

**Table 22-12. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. For more information about the module configuration, see <a href="#">Section 3.1.1.1.2, Module Level Clock Management</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Control Module	The module specific pad muxing must be set in the control module. For more information about the module configuration, see <a href="#">Section 18.4.8 PAD Functional Multiplexing and Configuration</a> , in <a href="#">Chapter 18, Control Module</a> .
MPU INTC	The MPU INTC configuration must be done to enable the interrupts from the GP timer module. See <a href="#">Interrupt Controller Registers</a> , in <a href="#">Chapter 4, Cortex-A9 MPU Subsystem</a> .
DSP INTC	The DSP INTC configuration must be done to enable the interrupts from GP timer module. See <a href="#">INTC</a> , in <a href="#">Chapter 5, DSP Subsystem</a> .

#### 22.2.5.1.2 GP Timer Module Global Initialization

##### 22.2.5.1.2.1 Main Sequence – GP Timer Module Global Initialization

This section identifies the main steps for initializing the GP timer module when the module is to be used for the first time.

**Table 22-13. GP Timer Module Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	GPT_TIOCP_CFG[0]SOFTRESET <sup>(1)</sup> or GPT1MS_TIOCP_CFG[0] SOFTRESET <sup>(2)</sup>	0x1
Wait until reset release?	GPT_TIOCP_CFG[0] SOFTRESET <sup>(1)</sup> or GPT1MS_TIOCP_CFG[0] SOFTRESET <sup>(2)</sup>	0x0
Configure Idle mode.	GPT_TIOCP_CFG[3:2] IDLEMODE <sup>(1)</sup> or GPT1MS_TIOCP_CFG[4:3] IDLEMODE <sup>(2)</sup>	xx
Configure clock activity.	GPT1MS_TIOCP_CFG[9:8] CLOCKACTIVITY <sup>(2)</sup>	xx
Configure wake-up feature.	GPT1MS_TIOCP_CFG[2] ENAWAKEUP <sup>(2)</sup>	x
Enable wake-up interrupt events.	GPT_IRQWAKEEN[2:0] <sup>(1)</sup> or GPT_TWERR[2:0] <sup>(2)</sup>	x
Select posted mode.	GPT_TSICR[2] POSTED	x

<sup>(1)</sup> Applies only to GPTIMER3 through GPTIMER9, and GPTIMER11

<sup>(2)</sup> Applies only to GPTIMER1, GPTIMER2, and GPTIMER10

## 22.2.5.2 Operational Mode Configuration

### 22.2.5.2.1 GP Timer Mode

#### 22.2.5.2.1.1 Main Sequence – GP Timer Mode Configuration

**Table 22-14. GP Timer Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode	GPT_TCLR[1] AR	x
Set prescale timer value.	GPT_TCLR[4:2] PTV	xxx
Enable prescaler.	GPT_TCLR[5] PRE	0x1
Enable overflow interrupt.	GPT_TIER[1] OVF_IT_ENA <sup>(1)</sup> or GPT_IRQENABLE_SET[1] OVF_EN_FLAG <sup>(2)</sup>	0x1
Load timer counter value.	GPT_TCRR	xxx
Load timer load value.	GPT_TLDR	xxx
Start the timer.	GPT_TCLR[0] ST	0x1

<sup>(1)</sup> Applies only to GPTIMER1, GPTIMER2, and GPTIMER10.

<sup>(2)</sup> Applies only to GPTIMER3 through GPTIMER 9, and GPTIMER11.

### 22.2.5.2.2 GP Timer Compare Mode

#### 22.2.5.2.2.1 Main Sequence – GP Timer Compare Mode Configuration

**Table 22-15. GP Timer Compare Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	GPT_TCLR[1] AR	x
Set prescale timer value.	GPT_TCLR[4:2] PTV	xxx
Enable prescaler.	GPT_TCLR[5] PRE	0x1
Enable match interrupt.	GPT_TIER[0] MAT_IT_ENA <sup>(1)</sup> or GPT_IRQENABLE_SET[0] MAT_EN_FLAG <sup>(2)</sup>	0x1
Load timer counter value.	GPT_TCRR	xxx
Load timer compare value.	GPT_TMAR	xxx
Enable Compare mode.	GPT_TCLR[6] CE	0x1
Start the timer.	GPT_TCLR[0] ST	0x1

<sup>(1)</sup> Applies only to GPTIMER1, GPTIMER2, and GPTIMER10.

<sup>(2)</sup> Applies only to GPTIMER3 through GPTIMER9, and GPTIMER11.

### 22.2.5.2.3 GP Timer Capture Mode

#### 22.2.5.2.3.1 Main Sequence – GP Timer Capture Mode Configuration

**Table 22-16. GP Timer Capture Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Initialize capture mode.	See <a href="#">Section 22.2.5.2.3.2</a> .	
Enable capture interrupt.	<a href="#">GPT_TIER[2]</a> TCAR_IT_ENA <sup>(1)</sup> or <a href="#">GPT_IRQENABLE_SET[2]</a> TCAR_EN_FLAG <sup>(2)</sup>	0x1
Start the timer.	<a href="#">GPT_TCLR[0]</a> ST	0x1
Detect event.	See <a href="#">Section 22.2.5.2.3.3</a> .	

<sup>(1)</sup> Applies only to GPTIMER1, GPTIMER2, and GPTIMER10.

<sup>(2)</sup> Applies only to GPTIMER3 through GPTIMER9, and GPTIMER11.

#### 22.2.5.2.3.2 Subsequence – Initialize Capture Mode

**Table 22-17. Initialize Capture Mode**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	<a href="#">GPT_TCLR[1]</a> AR	x
Set prescale timer value.	<a href="#">GPT_TCLR[4:2]</a> PTV	xxx
Enable prescaler.	<a href="#">GPT_TCLR[5]</a> PRE	0x1
Select GPTx (where x = 8 to 11). Capture input at device pin dmtimerx_pwm_evt.	<a href="#">GPT_TCLR[14]</a> GPO_CFG <sup>(1)</sup>	0x1
Select single or second event capture.	<a href="#">GPT_TCLR[13]</a> CAPT_MODE	x
Select transition capture mode.	<a href="#">GPT_TCLR[9:8]</a> TCM	xx

<sup>(1)</sup> Applies only to GPTIMER8 through GPTIMER11

#### 22.2.5.2.3.3 Subsequence – Detect Event

**Table 22-18. Detect Event**

Step	Register/Bit Field/Programming Model	Value
Wait until event detected?	<a href="#">GPT_TISR[2]</a> TCAR_IT_FLAG <sup>(1)</sup> or <a href="#">GPT_IRQSTATUS[2]</a> TCAR_IT_FLAG <sup>(2)</sup>	= 0x1
Read Timer capture value.	<a href="#">GPT_TCAR1</a> and/or <a href="#">GPT_TCAR2</a>	
Clear capture interrupt request.	<a href="#">GPT_TISR[2]</a> TCAR_IT_FLAG <sup>(1)</sup> or <a href="#">GPT_IRQSTATUS[2]</a> TCAR_IT_FLAG <sup>(2)</sup>	0x1

<sup>(1)</sup> Applies only to GPTIMER1, GPTIMER2, and GPTIMER10.

<sup>(2)</sup> Applies only to GPTIMER3 through GPTIMER9, and GPTIMER11.

### 22.2.5.2.4 GP Timer PWM Mode

#### 22.2.5.2.4.1 Main Sequence – GP Timer PWM Mode Configuration

**Table 22-19. GP Timer PWM Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	<a href="#">GPT_TCLR[1]</a> AR	x
Set prescale timer value.	<a href="#">GPT_TCLR[4:2]</a> PTV	xxx
Enable prescaler.	<a href="#">GPT_TCLR[5]</a> PRE	0x1
Select trigger output mode.	<a href="#">GPT_TCLR[11:10]</a> TRG	xx

**Table 22-19. GP Timer PWM Mode Configuration (continued)**

<b>Step</b>	<b>Register/Bit Field/Programming Model</b>	<b>Value</b>
Select pulse or toggle modulation PWM mode.	<a href="#">GPT_TCLR</a> [12] PT	x
Select GPTx (where x = 8 to 11) pwm output at device pin dmtimerx_pwm_evt.	<a href="#">GPT_TCLR</a> [14] GPO_CFG <sup>(1)</sup>	0x0
Configure PWM output pin default value.	<a href="#">GPT_TCLR</a> [7] SCPWM	x
Load timer load value.	<a href="#">GPT_TLDR</a>	xxx
Load timer compare value.	<a href="#">GPT_TMAR</a>	xxx
Enable compare.	<a href="#">GPT_TCLR</a> [6] CE	0x1
Start the timer.	<a href="#">GPT_TCLR</a> [0] ST	0x1

<sup>(1)</sup> Applies only to GPTIMER8 through GPTIMER11

## 22.2.6 GP Timer Register Manual

### 22.2.6.1 GP Timer Instance Summary

Table 22-20 lists the base address and block size for the GP timer module instances.

**Table 22-20. GP Timer Instance Summary**

Module Name	Base Address L4 Interconnect	Base Address L3 Interconnect	Base Address Cortex-A9 Private Access	Base Address DSP Private Access	Size
GPTIMER2	0x4803 2000	-	-	-	4 KB
GPTIMER3	0x4803 4000	-	-	-	4 KB
GPTIMER4	0x4803 6000	-	-	-	4 KB
GPTIMER9	0x4803 E000	-	-	-	4 KB
GPTIMER10	0x4808 6000	-	-	-	4 KB
GPTIMER11	0x4808 8000	-	-	-	4 KB
GPTIMER5	-	0x4903 8000	0x4013 8000	0x01D3 8000	4 KB
GPTIMER6	-	0x4903 A000	0x4013 A000	0x01D3 A000	4 KB
GPTIMER7	-	0x4903 C000	0x4013 C000	0x01D3 C000	4 KB
GPTIMER8	-	0x4903 E000	0x4013 E000	0x01D3 E000	4 KB
GPTIMER1	0x4A31 8000	-	-	-	4 KB

**NOTE:** Private Access is an access which is not using the L3/L4 interconnects.

### 22.2.6.2 GP Timer Registers

#### 22.2.6.2.1 GP Timer Register Summary

#### CAUTION

The GP timer registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 22-21 through Table 22-27 provide the register summary and associated offset addresses for the 11 GP timer internal registers.

**Table 22-21. GPTIMER1, GPTIMER2, and GPTIMER10 Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	GPTIMER1 Physical Address L4 Interconnect	GPTIMER2 Physical Address L4 Interconnect	GPTIMER10 Physical Address L4 Interconnect

RESERVED																												IDLEMODE	EMUFREE	SOFTRESET	

Bits	Field Name	Description	Type	Reset
31:4	RESERVED	Reserved	R	0x00000000
3:2	IDLEMODE	Power management, req/ack control  0x0: Force-idle mode: local target idle state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the IP module internal requirements. Back-up mode, for debug only.  0x1: No-idle mode: local target never enters idle state. Back-up mode, for debug only.  0x2: Smart-idle mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module should not generate (IRQ- or DMA-request-related) wake-up events.  0x3: Smart-idle wake-up-capable mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in idle state. Mode is only relevant if the appropriate IP module <i>wake-up</i> output(s) is (are) implemented.	RW	0x0
1	EMUFREE	Emulation mode  0x0: The timer is frozen in emulation mode (PINSUSPENDN signal active).  0x1: The timer runs free, regardless of PINSUSPENDN value.	RW	0
0	SOFTRESET	Software reset  0x0: Read 0: reset done, no pending action Write 0: No action  0x1: Read 1: initiate software reset Write 1: Reset ongoing	RW	0

<b>Address Offset</b>	0x0000 0038	<b>Instance</b>	GP TIMER
<b>Physical Address</b>	See <a href="#">Table 22-40</a> .		
<b>Description</b>	This register controls optional features specific to the timer functionality.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																GPO_CFG	CAPT_MODE	PT	TRG	TCM	SCPWM	CE	PRE	PTV	AR	ST					

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Reserved	R	0x00000
14	GPO_CFG	General-purpose output - this register directly drives the GPTi_PORGPOCFG output pin. For specific use of the GPO_CFG bit, see <a href="#">Section 22.2.2.1, GP Timer External System Interface</a> . 0x0: GPTi_PORGPOCFG drives 0. 0x1: GPTi_PORGPOCFG drives 1.	RW	0
13	CAPT_MODE	Capture mode select bit (first/second) 0x0: Single capture: Capture the first enabled capture event in TCAR1. 0x1: Capture on second event: Capture the second enabled capture event in TCAR2.	RW	0
12	PT	Pulse or toggle mode on GPTi_PWM_out output pin 0x0: Pulse modulation 0x1: Toggle modulation	RW	0
11:10	TRG	Trigger output mode on GPTi_PWM_out output pin 0x0: No trigger 0x1: Trigger on overflow. 0x2: Trigger on overflow and match. 0x3: Reserved	RW	0x0
9:8	TCM	Transition capture mode on GPTi_EVENT_CAPTURE input pin (When the TCM field passed from (00) to any other combination, the TCAR_IT_FLAG and the edge detection logic are cleared.) 0x0: No capture 0x1: Capture on rising edges of GPTi_EVENT_CAPTURE pin 0x2: Capture on falling edges of GPTi_EVENT_CAPTURE pin 0x3: Capture on both edges of GPTi_EVENT_CAPTURE pin	RW	0x0

## General-Purpose Timers

www.ti.com

Bits	Field Name	Description	Type	Reset
7	SCPWM	Pulse width modulation output pin default setting This bit must be set or clear while the timer is stopped or the trigger is off.  0x0: Clear the GPTi_PWM_out output pin and select positive pulse for pulse mode.  0x1: Set the GPTi_PWM_out output pin and select negative pulse for pulse mode.	RW	0
6	CE	Compare enable  0x0: Compare mode is disable.  0x1: Compare mode is enable.	RW	0
5	PRE	Prescaler enable  0x0: The TIMER clock input pin clocks the counter.  0x1: The divided input pin clocks the counter.	RW	0
4:2	PTV	Prescale clock timer value The timer counter is prescaled with the value $2^{(PTV+1)}$ . Example: PTV = 3, counter increases value (if started) after 16 functional clock periods.	RW	0x0
1	AR	Autoreload mode  0x0: One shot timer  0x1: Autoreload timer	RW	0
0	ST	Start/stop timer control  0x0: Stop timer: Only the counter is frozen. If one-shot mode selected (AR =0), this bit is automatically reset by internal logic when the counter is overflowed.  0x1: Start timer	RW	0

TIMER_COUNTER																																																																			

Bits	Field Name	Description	Type	Reset
31:0	TIMER_COUNTER	Value of TIMER counter	RW	0x0000 0000

**Table 22-47. Register Call Summary for Register GPT\_TCRR**

General-Purpose Timers

- Wake-Up Capability: [0] [1]
- Timer Mode Functionality: [2] [3] [4] [5] [6] [7] [8] [9] [10]
- 1-ms Tick Generation (Only GPTIMER1, GPTIMER2, and GPTIMER10): [11] [12] [13]
- Capture Mode Functionality: [14] [15]
- Compare Mode Functionality: [16] [17]
- Prescaler Functionality: [18] [19]
- Accessing GP Timer Registers: [20]
- Writing to Timer Registers: [21] [22] [23] [24]
- Reading From Timer Counter Registers: [25]
- GP Timer Mode: [26]
- GP Timer Compare Mode: [27]
- GP Timer Register Summary: [28] [29] [30] [31] [32] [33] [34]
- GP Timer Register Description: [35] [36]

**Table 22-48. GPT\_TLDR**

<b>Address Offset</b>	0x0000 0040	<b>Instance</b>	GP TIMER
<b>Physical Address</b>	See Table 22-40.		
<b>Description</b>	This register holds the timer load value.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LOAD_VALUE																															

Bits	Field Name	Description	Type	Reset
31:0	LOAD_VALUE	Timer counter value loaded on overflow in autoreload mode or on GPT_TTGR write access. LOAD_VALUE must be different than the timer overflow value (0xFFFF FFFF).	RW	0x0000 0000

**Table 22-49. Register Call Summary for Register GPT\_TLDR**

General-Purpose Timers

- Timer Mode Functionality: [0] [1] [2]
- 1-ms Tick Generation (Only GPTIMER1, GPTIMER2, and GPTIMER10): [3] [4] [5] [6] [7] [8] [9] [10] [11] [12]
- Prescaler Functionality: [13] [14]
- Pulse-Width Modulation: [15] [16] [17]
- Timer Counting Rate: [18] [19] [20] [21] [22]
- Accessing GP Timer Registers: [23]
- Writing to Timer Registers: [24] [25]
- GP Timer Mode: [26]
- GP Timer PWM Mode: [27]
- GP Timer Register Summary: [28] [29] [30] [31] [32] [33] [34]
- GP Timer Register Description: [35] [36]

**Table 22-50. GPT\_TTGR**

<b>Address Offset</b>	0x0000 0044	<b>Instance</b>	GP TIMER
<b>Physical Address</b>	See <a href="#">Table 22-40</a> .		
<b>Description</b>	The read value of this register is always 0xFFFF FFFF.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TTGR_VALUE																															

Bits	Field Name	Description	Type	Reset
31:0	TTGR_VALUE	Writing to the TTGR register causes the <a href="#">GPT_TCRR</a> to be loaded from <a href="#">GPT_TLDR</a> and the prescaler counter to be cleared. Reload is done regardless of the AR field value of the <a href="#">GPT_TCLR</a> register.	RW Rreturns 1s	0xFFFF FFFF
