## 22.3 Watchdog Timers

### 22.3.1 Watchdog Timers Overview

The device includes two instances of the 32-bit watchdog timer: WDT2 and WDT3. Figure 22-15 shows how each timer is connected in the device.

**NOTE:** WDT<sub>i</sub> (where *i* is the watchdog timer instance: *i* = 2 or 3) stands for the following:

- WDT2: Watchdog timer 2, also called MPU watchdog timer
- WDT3: Watchdog timer 3, also called IVA3 watchdog timer

Each watchdog timer is an upward counter capable of generating a pulse on the reset pin and an interrupt to the device system modules following an overflow condition. The MPU watchdog timer serves resets to the PRCM module (its interrupt outputs are unused), and the IVA3 watchdog timer serves watchdog interrupts to the MPU (its reset outputs are unused).

The watchdog timers can be accessed, loaded, and cleared by registers through the L4 interface. The MPU and IVA3 watchdog timers have the 32-kHz clock for their timer clock input.

The MPU watchdog timer directly generates a warm reset condition on overflow. The IVA3 watchdog timer generates an MPU interrupt condition on overflow, which can be used by the application software through the PRCM module to indirectly trigger a reset condition (that is, to the IVA3 subsystem).

The MPU watchdog timer connects to a single target agent port on the L4 interconnect.

**Figure 22-15. Watchdog Timers Block Diagram**

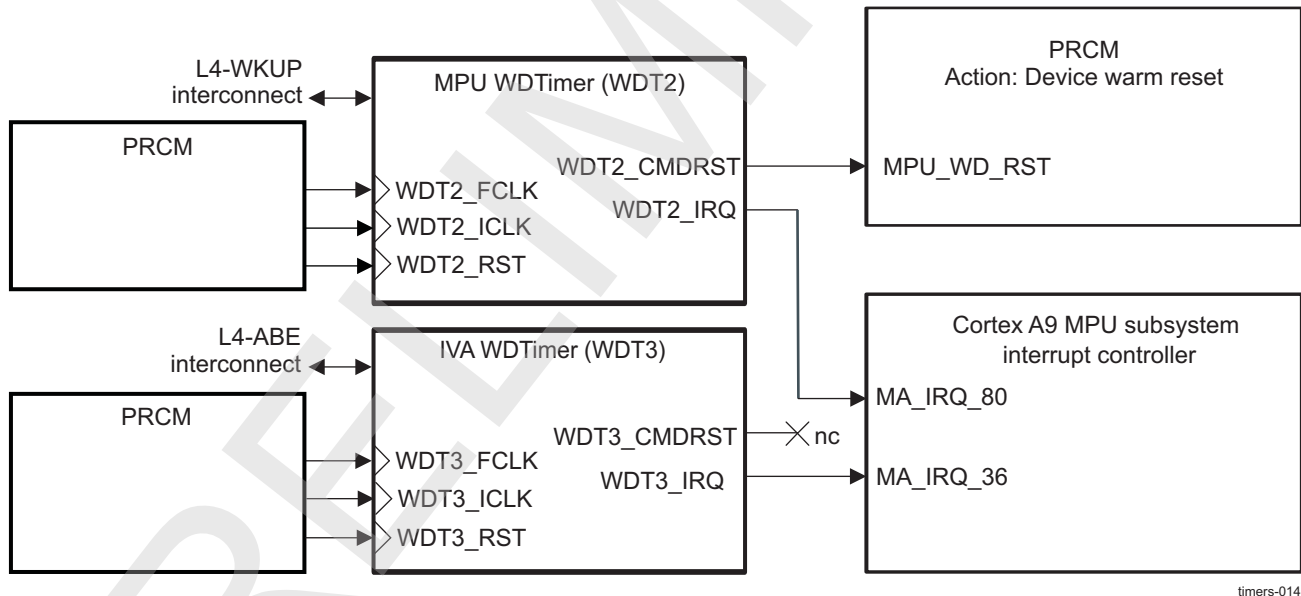

Table 22-80 lists the default state of the watchdog timers in the device.

**Table 22-80. Watchdog Timers Default State**

Timer	Default State	
MPU WDT2	Enabled	Not running
IVA3 WDT3	Enabled	Not running

---

**NOTE:** The default state of the watchdog timers described in [Table 22-80](#) is considered to be their state immediately after ROM code execution. For more information, see [Chapter 27, Initialization](#).

---

### 22.3.1.1 Watchdog Timers Features

The main features of the watchdog timer controllers are:

- L4 slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 11-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode only
- Free-running 32-bit upward counter
- Programmable divider clock source ( $2^n$  where  $n = [0:7]$ )
- On-the-fly read/write register (while counting)
- Subset programming model of the GP timer
- The watchdog timers are reset either on power-on or after a warm reset before they start counting.
- Reset or interrupt actions when a timer overflow condition occurs
- The watchdog timer generates a reset or an interrupt in its hardware integration (WDT2 or WDT3).

### 22.3.2 Watchdog Timer Environment

The watchdog timers are accessible through the L4 interface.

### 22.3.3 Watchdog Timer Integration

Figure 22-16 shows the integration of the watchdog timers in the device.

Figure 22-16. Watchdog Timers Integration

Table 22-81 through Table 22-83 summarize the integration of the module in the device.

Table 22-81. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
WDT2	PD_WKUP	Yes	L4_WKUP
WDT3	PD_AUDIO	Yes	L4_ABE

Table 22-82. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
WDT2	WDT2_FCLK	WKUP_32K_FCLK	PRCM	WDT2 functional clock
WDT2	WDT2_ICLK	WKUP_L4_ICLK2	PRCM	WDT2 interface clock
WDT3	WDT3_FCLK	ABE_ALWON_32K_CLK	PRCM	WDT3 functional clock
WDT3	WDT3_ICLK	ABE_ICLK2	PRCM	WDT3 interface clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
WDT2	WDT2_RST	WKUP_RST	PRM	Reset to WDT2
WDT2	MPU_WD_RST	WDT2_CMDRST	WDT2	Reset to PRCM
WDT3	WDT3_RST	AUDIO_RST	PRM	Reset to WDT3

**NOTE:** WDT2 is reset on power on or after a warm reset before it starts counting.

WDT3 is reset on power on or after a warm reset, and then it does not start counting.

**Table 22-83. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
WDT2	WDT2_IRQ	MA_IRQ_80	Cortex-A9 MPU	WDT2 interrupt to Cortex-A9 MPU
WDT3	WDT3_IRQ	MA_IRQ_36	Cortex-A9 MPU	IVA3 watchdog overflow
No DMA Requests				

**NOTE:**

- See [Section 22.3.4.2, Interrupts](#), for interrupt source description.

## 22.3.4 Watchdog Timers Functional Description

### 22.3.4.1 Power Management

There are two clock domains in the watchdog timers:

- Functional clock domain: WDTi\_FCLK is the watchdog timer functional clock. It is used to clock the watchdog timer internal logic.
- Interface clock domain: WDTi\_ICLK is the watchdog timer interface clock. It is used to synchronize the watchdog timer L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to WDTi\_ICLK.

Table 22-82 lists the source clocks for each watchdog timer in the device. For more information about clock control and domains, see Section 3.1.1.1, *Clock Management* in Chapter 3, *Power, Reset, and Clock Management*.

From a global system power-management perspective, when one or both of the watchdog timer clocks is no longer required, the watchdog timers can be deactivated at the PRCM module level in the corresponding registers.

At the PRCM module level, when the conditions to shut off the PRCM module functional or interface output clocks are met (for more information, see the Section 3.1.1.1.4, *Clock Domain Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the watchdog timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the watchdog timer.

Although this handshake is a hardware function and out of software control, the way the watchdog timer acknowledges the PRCM IDLE request is configurable through the WDT\_WDSC[4:3] IDLEMODE bit field. Table 22-84 lists the settings and related acknowledgment modes of the IDLEMODE bit field.

**Table 22-84. IDLEMODE Settings**

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The watchdog timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent loss of data when the clock is switched off.
01	No-idle	The watchdog timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM module output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The watchdog timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach for efficient system power management.
11	Smart-idle wakeup-capable mode	The watchdog timer acknowledges the IDLE request, basing its decision on its internal activity. The timer generates (IRQ-request-related) wake-up events when in IDLE state if the WDT_WIRQWAKEEN[1:0] bits are set to 1.

#### 22.3.4.1.1 Wake-Up Capability

If the WDT\_WDSC[4:3] IDLEMODE bit field sets smart-idle wakeup-capable mode (= 0 × 3), the timer evaluates its internal capability to have the interface clock switched off. When there is no more internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters into sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the WDT\_WIRQWAKEEN[0] OVF\_WK\_ENA and/or the WDT\_WIRQWAKEEN[1] DLY\_WK\_ENA bits enable the overflow and/or the delay wake-up capability.

#### 22.3.4.2 Interrupts

Table 22-85 list the event flags, and their masks, that cause module interrupts.

**Table 22-85. Watchdog Timer Events**

Event Flag	Event Mask	Mapping	Comments
WDT_WIRQSTAT[0] EVENT_OVF	WDT_WIRQENSET/WDT_WIRQENCLR[0] OVF_IT_ENA	WDTi_IRQ	Watchdog timer overflow
WDT_WIRQSTAT[1] EVENT_DLY	WDT_WIRQENSET/WDT_WIRQENCLR[1] DLY_IT_ENA	WDTi_IRQ	Watchdog delay value reached

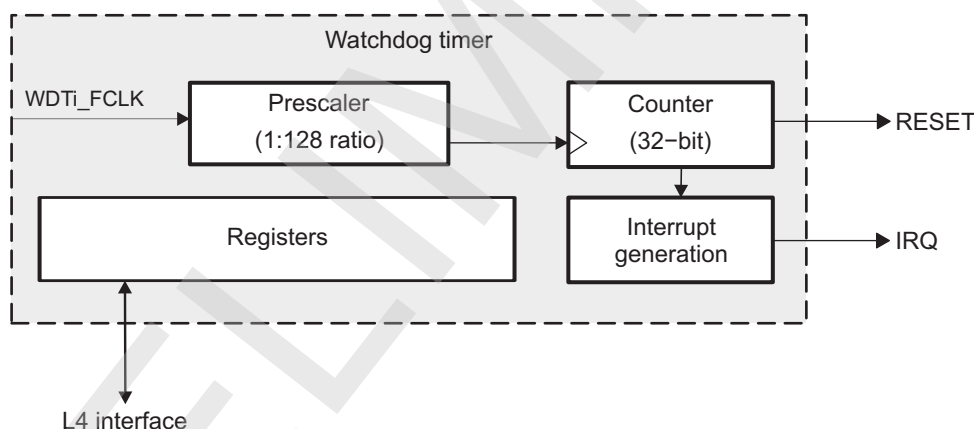

### 22.3.4.3 General Watchdog Timer Operation

The watchdog timers are based on an upward 32-bit counter coupled with a prescaler. The counter overflow is signaled through two independent signals: a simple reset signal and an interrupt signal, both active low. The use of these signals depends on whether they are connected or not. For this information, see [Figure 22-15](#). The interrupt generation mechanism is controlled through the [WDT\\_WIRQENSET/WDT\\_WIRQENCLR](#) and [WDT\\_WIRQSTAT](#) registers.

The prescaler ratio can be set from 1 to 128 by accessing the [WDT\\_WCLR\[4:2\]](#) PTV bit field and the [WDT\\_WCLR\[5\]](#) PRE bit of the watchdog control register ([WDT\\_WCLR](#)).

The current timer value can be accessed on-the-fly by reading the watchdog timer counter register ([WDT\\_WCRR](#)), modified by accessing the watchdog timer load register ([WDT\\_WLDR](#)) (no on-the-fly update), or reloaded by following a specific reload sequence on the watchdog timer trigger register ([WDT\\_WTGR](#)). A start/stop sequence applied to the watchdog timer start/stop register ([WDT\\_WSPR](#)) can start and stop the watchdog timers.

[Figure 22-17](#) is a functional block diagram of the watchdog timer.

**Figure 22-17. 32-Bit Watchdog Timer Functional Block Diagram**

timers-016

### 22.3.4.4 Reset Context

The watchdog timers are enabled after reset. [Table 22-86](#) lists the default reset values of the two watchdog timer load registers (the [WDT\\_WLDR](#)) and prescaler ratios (the [WDT\\_WCLR\[4:2\]](#) PTV bit field). To get these values, software must read the corresponding [WDT\\_WCLR\[4:2\]](#) PTV bit field and the 32-bit register to retrieve the static configuration of the module.

**Table 22-86. Count and Prescaler Default Reset Values**

Timer	WDT_WLDR Reset Value	PTV Reset Value
MPU WDT (WDT2)	0xFFFB 0000	0
IVA3 WDT (WDT3)	0xFFFB 0000	0

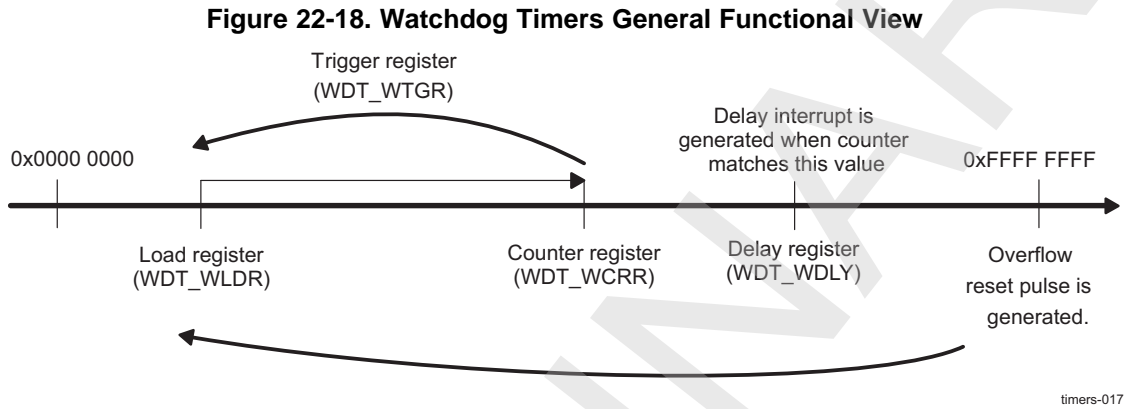

### 22.3.4.5 Overflow/Reset Generation

When the watchdog timer counter register ([WDT\\_WCRR](#)) overflows, an active-low reset pulse is generated to the PRCM module. This pulse is one prescaled timer clock cycle wide and occurs at the same time as the timer counter overflow.

After reset generation, the counter is automatically reloaded with the value stored in the watchdog load register ([WDT\\_WLDR](#)) and the prescaler is reset (the prescaler ratio remains unchanged). When the reset pulse output is generated, the timer counter begins incrementing again.

Figure 22-18 shows a general functional view of the watchdog timers.

### 22.3.4.6 Prescaler Value/Timer Reset Frequency

Each watchdog timer is composed of a prescaler stage and a timer counter.

The timer rate is defined by the following values:

- Value of the prescaler fields (the [WDT\\_WCLR\[5\]](#) PRE bit and the [WDT\\_WCLR\[4:2\]](#) PTV bit field)
- Value loaded into the timer load register ([WDT\\_WLDR](#))

The prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio is managed by accessing the ratio definition field (the [WDT\\_WCLR\[4:2\]](#) PTV bit field) and is enabled with the [WDT\\_WCLR\[5\]](#) PRE bit.

Table 22-87 lists the prescaler clock ratio values.

**Table 22-87. Prescaler Clock Ratio Values**

<a href="#">WDT_WCLR[5]</a> PRE	<a href="#">WDT_WCLR[4:2]</a> PTV	Clock Divider (PS)
0	X	1
1	0	1
1	1	2
1	2	4
1	3	8
1	4	16
1	5	32
1	6	64
1	7	128

Thus the watchdog timer overflow rate is expressed as:

$$\text{OVF\_Rate} = (0\text{x}\text{FFFF FFFF} - \text{WDT\_WLDR} + 1) \times (\text{wd-functional clock period}) \times \text{PS}$$

where wd-functional clock period =  $1/(\text{wd-functional clock frequency})$  and  $\text{PS} = 2^{(\text{PTV})}$

#### CAUTION

Internal resynchronization causes some latency in any software write to [WDT\\_WSPR](#) before [WDT\\_WSPR](#) is updated with the programmed value:

$1.5 \times \text{functional clock cycles} \leq \text{write\_WDT\_WSPR\_latency} \leq 2.5 \times \text{functional clock cycles}$

Remember to consider this latency whenever the watchdog timer must be started or stopped.

For example, for a timer clock input of 32 kHz with a prescaler ratio value of 0x1 (clock divided by 2) and [WDT\\_WCLR](#)[5] PRE = 1 (clock divider enabled), the reset period is as listed in [Table 22-88](#).

**Table 22-88. Reset Period Examples**

<a href="#">WDT_WLDR</a> Value	Reset Period
0x0000 0000	74 h 56 min
0xFFFF 0000	4 s
0xFFFF FFF0	1 ms
0xFFFF FFFF	62.5 us

#### CAUTION

- Ensure that the reloaded value allows the correct operation of the application. When a watchdog timer is enabled, software must periodically trigger a reload before the counter overflows. Hence, the value of the [WDT\\_WLDR](#)[31:0] bit field must be chosen according to the ongoing activity preceding the watchdog reload.
- Due to design reasons, [WDT\\_WLDR](#)[31:0] = 0xFFFF FFFF is a special case, although such a value of [WDT\\_WLDR](#) is meaningless. When [WDT\\_WLDR](#) is programmed with the overflow value, a triggering event generates a reset/interrupt one functional clock cycle later, even if the watchdog timer is stopped.

[Table 22-89](#) lists the default reset periods for the watchdog timers.

**Table 22-89. Default Watchdog Timer Reset Periods**

Watchdog Timers	Clock Source	Default Reset Period
MPU/IVA3 WDTs	32 kHz	10 s

### 22.3.4.7 Triggering a Timer Reload

To reload the timer counter and reset the prescaler before reaching overflow, a reload command is executed by accessing the watchdog timer trigger register ([WDT\\_WTGR](#)) using a specific reload sequence.

The specific reload sequence is performed whenever the written value on the [WDT\\_WTGR](#) register differs from its previous value. In this case, reload is executed in the same way as an overflow autoreload, but without the generation of a reset pulse.

The timer counter is loaded with the value of the watchdog timer load register (the [WDT\\_WLDR\[31:0\] TIMER\\_LOAD](#) bit field), and the prescaler is reset.

#### 22.3.4.8 Start/Stop Sequence for Watchdog Timers (Using the WDT\_WSPR Register)

To start and stop a watchdog timer, access must be made through the start/stop register ([WDT\\_WSPR](#)) using a specific sequence.

To disable the timer, follow this sequence:

1. Write 0xXXXX AAAA in [WDT\\_WSPR](#).
2. Write 0xXXXX 5555 in [WDT\\_WSPR](#).

To enable the timer, follow this sequence:

1. Write 0xXXXX BBBB in [WDT\\_WSPR](#).
2. Write 0xXXXX 4444 in [WDT\\_WSPR](#).

All other write sequences on the [WDT\\_WSPR](#) register have no effect on the start/stop feature of the module.

#### 22.3.4.9 Modifying Timer Count/Load Values and Prescaler Setting

To modify the timer counter value (the [WDT\\_WCRR](#) register), prescaler ratio (the [WDT\\_WCLR\[4:2\] PTV](#) bit field), delay configuration value (the [WDT\\_WDLY\[31:0\] DLY\\_VALUE](#) bit field), or the load value (the [WDT\\_WLDR\[31:0\] TIMER\\_LOAD](#) bit field), the watchdog timer must be disabled by using the start/stop sequence (the [WDT\\_WSPR](#) register).

After a write access, the load register value and prescaler ratio registers are updated immediately, but new values are considered only after the next consecutive counter overflow or after a new trigger command (the [WDT\\_WTGR](#) register).

#### 22.3.4.10 Watchdog Counter Register Access Restriction (WDT\_WCRR Register)

A 32-bit shadow register is implemented to read a coherent value of the [WDT\\_WCRR](#) register because the [WDT\\_WCRR](#) register is directly related to the timer counter value and is updated on the timer clock ([WDT\\_FCLK](#)). The shadow register is updated by a 16-bit LSB read command.

---

**NOTE:** Although the L4 clock ([WDT\\_ICLK](#)) is completely asynchronous with the timer clock ([WDT\\_FCLK](#)), some synchronization is performed to ensure that the value of the [WDT\\_WCRR](#) register is not read while it is being incremented.

---

When 32-bit read access is performed, the shadow register is not updated. Read access is performed directly from the accessed register.

To ensure that a coherent value is read inside [WDT\\_WCRR](#), the first read access is to the lower 16 bits (offset = 0x08), followed by read access to the upper 16 bits (offset = 0x0A).

#### 22.3.4.11 Watchdog Timer Interrupt Generation

When an interrupt source occurs, the interrupt status bit (the [WDT\\_WIRQSTAT\[0\] EVENT\\_OVF](#) or [WDT\\_WIRQSTAT\[1\] EVENT\\_DLY](#) bit) is set to 1. The output interrupt line ([WDTi\\_IRQ](#)) is asserted (active low) when status (the [EVENT\\_XXX](#) bit) and enable (the [XXX\\_IT\\_ENA](#) bit) flags are set to 1; the order is not relevant. Writing 1 to the enable bit (the status is already set at 1) also triggers the interrupt in the normal order (enable first, status next). The pending interrupt event is cleared when the set status bit is overwritten by a value of 1 by a write command in the [WDT\\_WIRQSTAT](#) register. Reading the [WDT\\_WIRQSTAT](#) register and writing the value back allows a fast interrupt acknowledge process.

The watchdog timer issues an overflow interrupt if this interrupt is enabled in the watchdog interrupt enable register ([WDT\\_WIRQENSET\[0\] OVF\\_IT\\_ENA](#) = 1). When the overflow occurs, the interrupt status bit (the [WDT\\_WIRQSTAT\[0\] EVENT\\_OVF](#) bit) is set to 1. The output interrupt line ([WDT\\_IRQ](#)) is asserted (active low) when status ([EVENT\\_OVF](#)) and enable ([OVF\\_IT\\_ENA](#)) flags are set to 1; the order is not relevant. This interrupt can be disabled by setting the [WDT\\_WIRQENCLR\[0\] OVF\\_IT\\_ENA](#) bit to 1.

The watchdog can issue the delay interrupt if this interrupt is enabled in the interrupt enable register ([WDT\\_WIRQENSET\[1\] DLY\\_IT\\_ENA = 1](#)). When the counter is running and the counter value matches the value stored in the delay configuration register ([WDT\\_WDLY](#)), the corresponding interrupt status bit is set in the watchdog status register ([WDT\\_WIRQSTAT](#)) and the output interrupt line is asserted (active low) when the flag ([EVENT\\_DLY](#)) and enable ([DLY\\_IT\\_ENA](#)) bits are 1 in the [WDT\\_WIRQSTAT](#) and [WDT\\_WIRQENSET](#) registers, respectively; the order (normally enable, then flag), is not relevant. This interrupt can be disabled by setting the [WDT\\_WIRQENCLR\[1\] DLY\\_IT\\_ENA](#) bit to 1.

---

**NOTE:** Writing 0 to the [WDT\\_WIRQSTAT\[0\] EVENT\\_OVF](#) bit or the [WDT\\_WIRQSTAT\[1\] EVENT\\_DLY](#) bit has no effect.

---

The two clock domains are resynchronized because the interrupt event is generated on the functional clock domain ([WDTi\\_FCLK](#)) during the updating of the interrupt status register ([WDT\\_WIRQSTAT](#)).

The [WDT\\_WDLY](#) register is used to specify the value of the delay configuration register. The delay time to interrupt is the difference between the reload value stored in the counter load register ([WDT\\_WLDR](#)) and the programmed value in this register ([WDT\\_WDLY](#)).

Use the following formula to estimate the delay time:

Delay time period = ([WDT\\_WDLY](#) – [WDT\\_WLDR](#) + 1) × Timer clock period × Clock divider

Where:

- Timer clock period = 1/(Timer clock frequency)
- Clock divider = 2PTV

If the counter value ([WDT\\_WCRR](#)) reaches the programmed value ([WDT\\_WDLY](#)), the status bit ([EVENT\\_DLY](#)) gets set in the interrupt status register ([WDT\\_WIRQSTAT](#)), and an interrupt occurs if the corresponding enable bit is set in the interrupt enable register ([WDT\\_WIRQENSET](#)).

#### CAUTION

If the reload event occurs (after a triggering sequence or after a reset sequence) before reaching the programmed value ([WDT\\_WDLY\[31:0\] WDLY\\_VALUE](#)), no interrupt is generated.

Also, no interrupt is generated if the value programmed in the delay configuration register ([WDT\\_WDLY](#)) is less than the value stored in the counter load register ([WDT\\_WLDR](#)).

#### 22.3.4.12 Watchdog Timers Under Emulation

During emulation mode, the watchdog timer can/cannot continue running, according to the value of the [WDT\\_WDSC\[5\] EMUFREE](#) bit of the system configuration register ([WDT\\_WDSC](#)).

- When [EMUFREE](#) is 1, watchdog timer execution is not stopped and a reset pulse is still generated when overflow is reached.
- When [EMUFREE](#) is 0, the counters (prescaler/timer) are frozen and incrementation restarts after exiting from emulation mode.

#### 22.3.4.13 Accessing Watchdog Timer Registers

Posted/nonposted selection applies only to functional registers that require synchronization on/from the timer functional clock domain ([WDTi\\_FCLK](#)). For write/read operation, the following registers are affected:

- [WDT\\_WCLR](#)
- [WDT\\_WCRR](#)
- [WDT\\_WLDR](#)
- [WDT\\_WTGR](#)
- [WDT\\_WDLY](#)
- [WDT\\_WSPR](#)

The timer interface clock domain synchronous registers are not affected by the posted/nonposted selection; the write/read operation is effective and acknowledged (command accepted) after one WDT\_ICLK cycle from the command assertion. The timer interface clock domain synchronous registers are:

- [WDT\\_WIDR](#)
- [WDT\\_WDSC](#)
- [WDT\\_WDST](#)
- [WDT\\_WIRQSTATRAW](#)
- [WDT\\_WIRQSTAT](#)
- [WDT\\_WIRQENSET](#)
- [WDT\\_WIRQENCLR](#)
- [WDT\\_WIRQWAKEEN](#)
- [WDT\\_WWPS](#)

---

**NOTE:** Accesses to WDT2 and WDT3 are posted.

---

### 22.3.5 Watchdog Timer Low-Level Programming Model

This section covers the low-level hardware programming sequences for configuration and use of the module.

#### 22.3.5.1 Global Initialization

##### 22.3.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the watchdog timer is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the watchdog timer (see [Table 22-90](#)). For more information, see [Section 22.3.2, Watchdog Timer Environment](#), and [Section 22.3.3, Watchdog Timer Integration](#).

**Table 22-90. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. for more information about the module configuration. For more information about the module configuration, see <a href="#">Section 3.1.1.1.2, Module Level Clock Management</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Control module	Module-specific pad muxing must be set in the control module. For more information about the module configuration, see <a href="#">Section 18.4.8, PAD Functional Multiplexing and Configuration</a> in <a href="#">Chapter 18, Control Module</a> .
MPU INTC	The MPU INTC configuration must be performed to enable the interrupts from the watchdog timer. See <a href="#">, Interrupt Controller Registers</a> in <a href="#">Chapter 4, Cortex-A9 MPU Subsystem</a> .

### 22.3.5.1.2 Watchdog Timer Module Global Initialization

#### 22.3.5.1.2.1 Main Sequence – Watchdog Timer Module Global Initialization

Table 22-91 lists the steps for initializing the watchdog timer module when the module is to be used for the first time.

**Table 22-91. Watchdog Timer Module Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	WDT_WDSC[1] SOFTRESET	0x1
Wait until reset release?	WDT_WDSC[1] SOFTRESET	0x0
Configure idle mode.	WDT_WDSC[4:3] IDLEMODE	xx
Enable delay wakeup.	WDT_WIRQWAKEEN[1] DLY_WK_ENA	0x1
Enable overflow wakeup.	WDT_WIRQWAKEEN[0] OVF_WK_ENA	0x1
Enable delay interrupt.	WDT_WIRQENSET[1] ENABLE_DLY	0x1
Enable overflow interrupt.	WDT_WIRQENSET[0] ENABLE_OVF	0x1

### 22.3.5.2 Operational Mode Configuration

#### 22.3.5.2.1 Watchdog Timer Basic Configuration

##### 22.3.5.2.1.1 Main Sequence – Watchdog Timer Basic Configuration

Table 22-92 lists the steps for the basic configuration of the watchdog timer.

**Table 22-92. Watchdog Timer Basic Configuration**

Step	Register/Bit Field/Programming Model	Value
Disable the watchdog timer.	See Section 22.3.5.2.1.2.	
Set prescaler value.	WDT_WCLR[4:2] PTV	xxx
Enable prescaler.	WDT_WCLR[5] PRE	0x1
Load delay configuration value.	WDT_WDLY	xxx
Load timer counter value.	WDT_WCRR	xxx
Enable the watchdog timer.	See Section 22.3.5.2.1.3.	

##### 22.3.5.2.1.2 Subsequence – Disable the Watchdog Timer

Table 22-93 lists the steps to disable the watchdog timer.

**Table 22-93. Disable the Watchdog Timer**

Step	Register/Bit Field/Programming Model	Value
Write disable sequence Data1.	WDT_WSPR	0xXXXX AAAA
Write disable sequence Data2.	WDT_WSPR	0xXXXX 5555

##### 22.3.5.2.1.3 Subsequence – Enable the Watchdog Timer

Table 22-94 lists the steps to enable the watchdog timer.

**Table 22-94. Enable the Watchdog Timer**

Step	Register/Bit Field/Programming Model	Value
Write enable sequence Data1.	WDT_WSPR	0xXXXX BBBB
Write enable sequence Data2.	WDT_WSPR	0xXXXX 4444

## 22.3.6 Watchdog Timer Register Manual

### 22.3.6.1 Watchdog Timer Instance Summary

Table 22-95 lists the base address and address space for the watchdog timer module instances.

**Table 22-95. Watchdog Timer Instance Summary**

Module Name	Base Address L4 Interconnect	Base Address L3 Interconnect	Base Address Cortex-A9 Private Access	Base Address DSP Private Access	Size
WDTIMER2	0x4A31 4000	-	-	-	4KB
WDTIMER3	-	0x4903 0000	0x4013 0000	0x01D3 0000	4KB

**NOTE:** Private access is an access which is not using the L3/L4 interconnects.

### 22.3.6.2 Watchdog Timer Registers

#### 22.3.6.2.1 Watchdog Timer Register Summary

**CAUTION**

The watchdog timers registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt register content.

Table 22-96 lists the WDTIMER2 registers.

**Table 22-96. WDTIMER2 Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address L4 Interconnect
WDT_WIDR	R	32	0x0000 0000	0x4A31 4000
WDT_WDSC	RW	32	0x0000 0010	0x4A31 4010

## 22.4 32-kHz Synchronized Timer

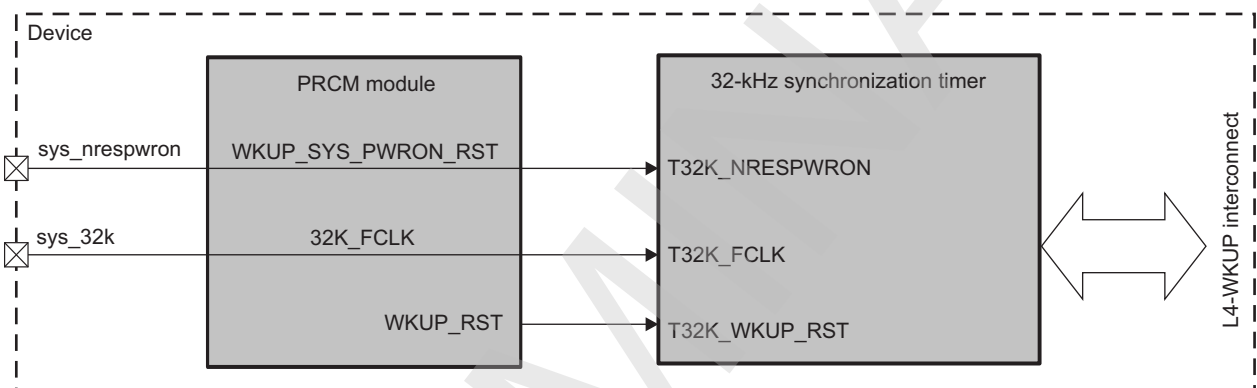

### 22.4.1 32-kHz Synchronized Timer Overview

The 32-kHz synchronized timer is a 32-bit counter clocked by the falling edge of the 32-kHz system clock. It is reset while the external asynchronous power-up reset (`sys_nrespwron`) primary input/output (I/O) is active (main device reset). When `sys_nrespwron` is released (on the rising edge of `sys_nrespwron`), after three 32-kHz clock periods, the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock. After reaching its highest value, the counter wraps back to 0 and starts counting again.

Figure 22-19 is the block diagram of the 32-kHz synchronized timer.

**NOTE:** `sys_nrespwron` is an active-low I/O.

Figure 22-19. 32-kHz Synchronized Timer Block Diagram

timers-018

#### 22.4.1.1 32-kHz Synchronized Timer Features

The main features of the 32-kHz synchronized timer controller are:

- L4 slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 5-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode supported
- Only read operations are supported on the module registers; no write operation is supported (no error/no action on write).
- Free-running 32-bit upward counter
- Start and keep counting after power-on reset
- Automatic roll over to 0; highest value reached: 0xFFFF FFFF
- On-the-fly read (while counting)

#### 22.4.2 32-kHz Synchronized Timer Environment

The synchronized timer is accessible only through the L4 interface.

#### 22.4.3 32-kHz Synchronized Timer Integration

Table 22-134 through Table 22-136 summarize the integration of the module in the device.

**Table 22-134. Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect

#### 22.4.4 32-kHz Synchronized Timer Functional Description

The synchronized timer is a counter that starts on the rising edge of an external asynchronous signal (`sys_nrespwron`). When `sys_nrespwron` is released (on the rising edge of `sys_nrespwron`), the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock after three inverted 32-kHz clock periods. After reaching its highest value, the counter wraps back to 0 and starts counting again with no additional delay. When `sys_nrespwron` is released (on the rising edge of `sys_nrespwron`), after three inverted 32-kHz clock periods, the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock.

Figure 22-20 shows the reset synchronization timing diagram. After reaching its highest value, the counter wraps back to 0 and starts counting again without any extra delay.

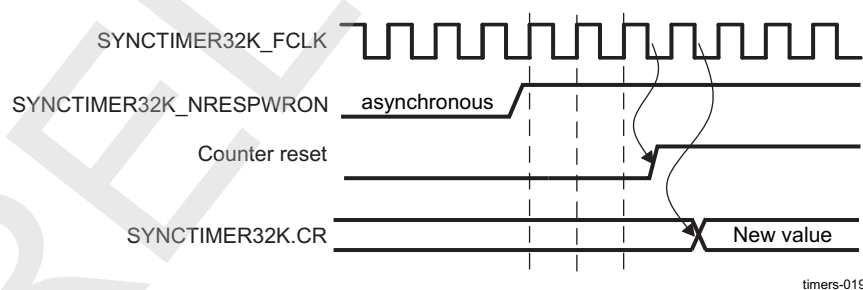

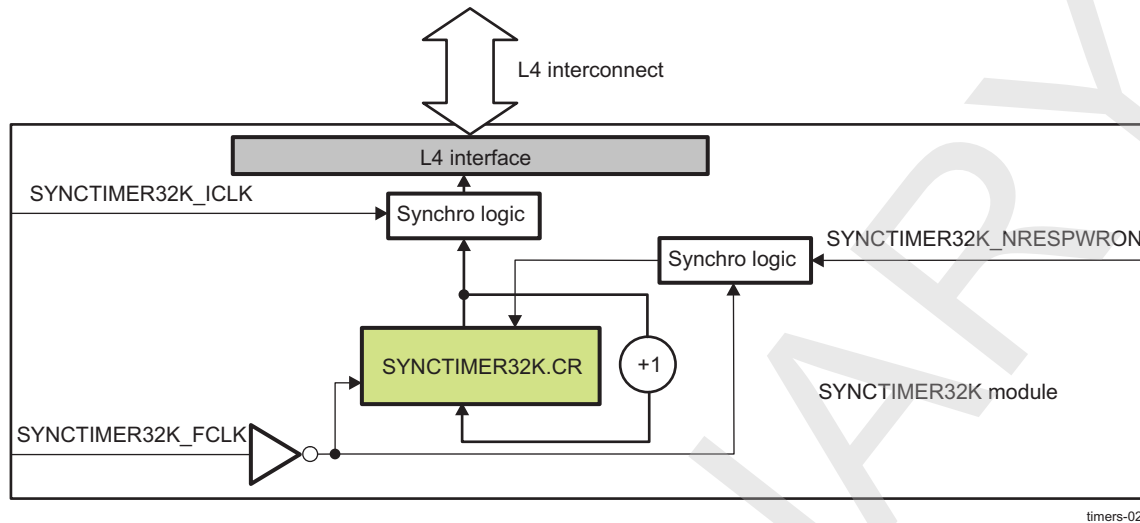

**Figure 22-20. Reset Resynchronization Timing Diagram**

Figure 22-21 is the block diagram of the synchronized timer.

**NOTE:** `sys_nrespwron` is an active-low input.

Figure 22-21. SYNCTIMER32K Block Diagram

The sync logic ensures the read transaction correctness by synchronizing the counter register read access on 32KSYNCNT\_ICLK because the 32KSYNCNT\_ICLK clock signal is completely asynchronous with S32KSYNCNT\_FCLK. The sys\_nrespwron input resets the counter register (32KSYNCNT\_CR). The inverted 32KSYNCNT\_FCLK clocks the sys\_nrespwron reset signal.

#### 22.4.4.1 Reading the 32-kHz Synchronized Timer

The counter register (32KSYNCNT\_CR) is 32 bits wide. For correct count capture, it must be accessed as 16-bit LSB access first and 16-bit MSB access next. Internal synchronization logic allows reading of the counter value with 32KSYNCNT\_ICLK while the counter is running. The time latency to read the synchronized counter register is one 32KSYNCNT\_ICLK clock period.

## 22.4.5 32KTimer Register Manual

Table 22-137 lists the base address and block size for the 32-kHz synchronized timer. It is memory mapped to the L4 peripheral bus memory space.

**Table 22-137. 32KTimer Instance Summary**

Module Name	Base Address L4 Interconnect	Size
32KTimer	0x4A30 4000	4KB

### 22.4.5.1 32KTimer Register Mapping Summary

#### CAUTION

The 32-kHz synchronized timer registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 22-138 lists the 32-kHz synchronized timer registers. Table 22-139 through Table 22-143 describe the register bits.

**Table 22-138. 32KTimer Register Summary**

## 23.1 Multimaster High-Speed I<sup>2</sup>C Controller

### 23.1.1 HS I<sup>2</sup>C Overview

The device contains four multimaster high-speed (HS) inter-integrated circuit (I<sup>2</sup>C) controllers (I2Ci modules, where i = 1, 2, 3, 4), each of which provides an interface between a local host (LH), such as a digital signal processor (DSP), and any I<sup>2</sup>C-bus-compatible device that connects through the I<sup>2</sup>C serial bus. External components attached to the I<sup>2</sup>C bus can serially transmit and receive up to 8 bits of data to and from the LH device through the 2-wire I<sup>2</sup>C interface.

Each multimaster HS I<sup>2</sup>C controller can be configured to act like a slave or master I<sup>2</sup>C-compatible device. Moreover, each multimaster HS I<sup>2</sup>C controller can be configured in serial camera control bus (SCCB) mode (the SCCB is a serial bus developed by Omnivision Technologies, Inc.) to act as a master on a 2-wire SCCB bus. Only multimaster HS I<sup>2</sup>C controllers I2C2 and I2C3 can be configured in SCCB mode to act as a master device on a 3-wire SCCB bus.

The device contains an additional fifth master transmitter HS I<sup>2</sup>C interface (I2C5) in the power, reset, and clock management (PRCM) module to perform dynamic voltage control and power sequencing with an external power integrated circuit (IC).

Figure 23-1 shows the I<sup>2</sup>C.

Figure 23-1. HS I<sup>2</sup>C Controllers

The four multimaster HS I<sup>2</sup>C controllers have the following features:

- Compliant with Philips I2C specification version 3.0
- Supports a standard mode (up to 100 Kbps), fast mode (up to 400 Kbps) and fast mode+ (up to 1 Mbps)
- Supports High-speed (HS) mode for transfer up to 3.4 Mbps

- Support for 3-wire/2-wire SCCB master mode for I2C2 and I2C3 modules, 2-wire SCCB master mode for I2C1 and I2C4 modules, up to 100 Kbps
- 7-bit and 10-bit device addressing modes
- General call
- Start/Restart/Stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in configurable FIFOs (8, 16, 32, 64 bytes) for buffered read or write
- Module enable/disable capability
- Programmable multislave channel (responds to four separate addresses)
- Programmable clock generation
- 8-bit wide data access
- Open-core protocol (OCP) interface with LH application (OCP-IP 2.0 compliant)
- Designed for low power consumption
- Implement Auto Idle mechanism
- Implement Idle Request/Idle Acknowledge handshake mechanism
- Support for asynchronous wake-up mechanism
- Two direct memory access (DMA) channels
- Wide interrupt capability
- Supports OmniVision SCCB protocol
- Compliant with Highlander 0.8

The master transmitter HS I<sup>2</sup>C controller I2C5 has the following features:

- Support of HS and fast modes
- 7-bit addressing mode only
- Master transmitter mode only
- Start/restart/stop

---

**NOTE:** Before using HS I<sup>2</sup>C mode, determine that the target device supports this mode.

---

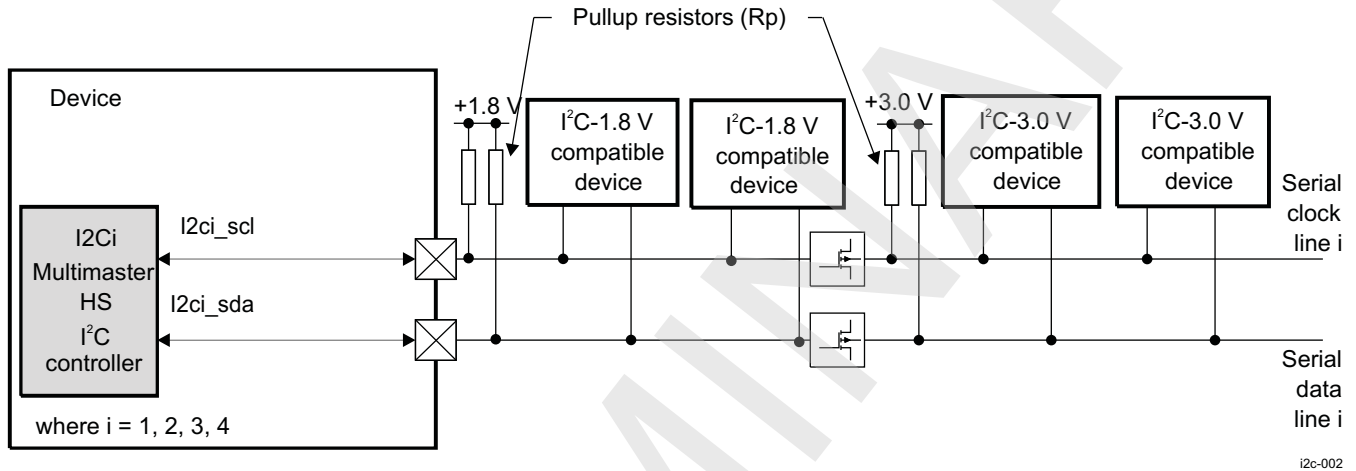

### 23.1.2 HS I<sup>2</sup>C Environment

This section describes the HS I<sup>2</sup>C application fields from an environment point of view (external connections). It describes HS I<sup>2</sup>C connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

#### 23.1.2.1 HS I<sup>2</sup>C in I<sup>2</sup>C Mode

Figure 23-2 shows the multimaster HS I<sup>2</sup>C controllers and their related connections with I<sup>2</sup>C-compliant devices in I<sup>2</sup>C mode.

Figure 23-2. HS I<sup>2</sup>C and Typical Connections to I<sup>2</sup>C Devices

#### 23.1.2.1.1 HS I<sup>2</sup>C Pins for Typical Connections in I<sup>2</sup>C Mode

Figure 23-3 shows the multimaster HS I<sup>2</sup>C controller pins used for typical connections with I<sup>2</sup>C devices.

Figure 23-3. HS I<sup>2</sup>C Interface Signals in I<sup>2</sup>C Mode

#### 23.1.2.1.2 HS I<sup>2</sup>C Interface Typical Connections

Table 23-1 lists the pins associated with the I<sup>2</sup>C interface.

Table 23-1. HS I<sup>2</sup>C Input/Output

Signal	I/O <sup>(1)</sup>	Description	Reset Value
i2ci_scl	I/O	I <sup>2</sup> C serial clock line <sup>(2)</sup> . Open-drain output buffer. Requires external pullup resistor (Rp).	1
i2ci_sda	I/O	I <sup>2</sup> C serial data line. Open-drain output buffer. Requires external Rp.	1

<sup>(1)</sup> I = Input; O = Output

<sup>(2)</sup> This output signal is also used as retiming input.

### 23.1.2.1.3 HS I<sup>2</sup>C Typical Connection Protocol and Data Format

#### 23.1.2.1.3.1 HS I<sup>2</sup>C Serial Data Format

The I<sup>2</sup>C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I<sup>2</sup>C. Figure 23-4 shows a typical I<sup>2</sup>C communication format.

**Figure 23-4. HS I<sup>2</sup>C Data Transfer**

#### 23.1.2.1.3.2 HS I<sup>2</sup>C Data Validity

The data on the serial data line (SDA) must be stable during the high period of the serial clock line. The high and low states of the data line can change only when the clock signal on the serial clock line (SCK) is low.

Figure 23-5 is an example of data validity requirements.

**Figure 23-5. HS I<sup>2</sup>C Bit Transfer on the I<sup>2</sup>C Bus**

#### 23.1.2.1.3.3 HS I<sup>2</sup>C Start and Stop Conditions

The I<sup>2</sup>C module generates start (S) and stop (P) conditions when it is configured as a master.

- An S condition is a high-to-low transition on the serial data line while serial clock line is high.
- A P condition is a low-to-high transition on the serial data line while serial clock line is high.

The bus is considered busy after the S condition (the `I2Ci.I2C_STAT[12]` BB bit is 1 to indicate that the bus is busy) and free after the P condition (the `I2Ci.I2C_STAT[12]` BB bit is 0 to indicate that the bus is free).

Figure 23-6 shows the waveforms that occur during an S and a P condition.

Figure 23-6. HS I<sup>2</sup>C S and P Condition Events

23.1.2.1.3.4 HS I<sup>2</sup>C Addressing

The I<sup>2</sup>C module supports two data formats in fast/standard (F/S) and HS modes:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

23.1.2.1.3.4.1 Data Transfer Formats in F/S Mode

Figure 23-7 shows the I<sup>2</sup>C data transfer formats in F/S mode.

Figure 23-7. HS I<sup>2</sup>C Data Transfer Formats in F/S Mode

(a) 7-bit addressing format

(b) 10-bit addressing format

(c) Addressing format with repeated start condition

i2c-007

The first word after an S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 least-significant bit (LSB) R/W<sub>-</sub> bit.

The LSB R/W<sub>-</sub> bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W<sub>-</sub> is 0, the master writes data to the selected slave; if it is 1, the master reads data from the slave.

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the 2 MSBs of the 10-bit addresses, and Y is the R/W<sub>-</sub> bit. If the R/W<sub>-</sub> bit is 0, the next byte contains the last 8 bits of the slave address. If the R/W<sub>-</sub> bit is 1, the next byte contains data transmitted from the slave to the master.

### 23.1.2.1.3.4.2 Data Transfer Format in HS Mode

Figure 23-8 shows the I<sup>2</sup>C data transfer format in HS mode.

**Figure 23-8. HS I<sup>2</sup>C Data Transfer in HS Mode**

i2c-008

Each multimaster HS I<sup>2</sup>C controller can also operate in HS mode. In this case, after the S condition, the module, which is in F/S mode, writes the master code address (000001XXX, where XXX is the variable portion of the master code) on the bus. No device connected on the same bus acknowledges this address. The module switches the clock to the HS clock and after an Sr condition, and sends the slave address and the data, as shown in Figure 23-8.

### 23.1.2.1.3.5 HS I<sup>2</sup>C Master Transmitter

In master transmitter mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in sync with the self-generated clock pulses on the serial clock line SCL. The clock pulses are inhibited and SCL is held low when the intervention of the processor is required (XUDF) after a byte is transmitted.

### 23.1.2.1.3.6 HS I<sup>2</sup>C Master Receiver

Master receiver mode can be entered only from master transmitter mode. With any of the address formats (a), (b), or (c) (see Figure 23-7), if R/W<sub>0</sub> is high, the module enters master receiver mode after the slave address byte and bit R/W<sub>0</sub> are transmitted. Serial data bits received on bus line SDA are shifted in synchronization with the self-generated clock pulses on SCL.

### 23.1.2.1.3.7 HS I<sup>2</sup>C Slave Transmitter

Slave transmitter mode can be entered only from slave receiver mode. With any of the address formats (a), (b), or (c) (see Figure 23-7), the slave transmitter is entered if the slave address byte is the same as its own address and bit R/W<sub>0</sub> is transmitted, if R/W<sub>0</sub> is high. The slave transmitter shifts the serial data out on the data line SDA in sync with the clock pulses that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (XUDF).

### 23.1.2.1.3.8 HS I<sup>2</sup>C Slave Receiver

In this mode, serial data bits received on the bus line SDA are shifted-in in sync with the clock pulses on SCL that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (ROVR) after a byte is received.

### 23.1.2.1.3.9 HS I<sup>2</sup>C Bus Arbitration

If two or more master transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration lost interrupt. Figure 23-9 shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 23-9. HS I<sup>2</sup>C Arbitration Between Master Transmitters

### 23.1.2.1.3.10 HS I<sup>2</sup>C Clock Generation and Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more master devices and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generation of their own low period. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period. If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a slave can slow down a fast master and the slow device can create enough time to store a received byte or prepare a byte to be transmitted.

Figure 23-10 shows clock synchronization.

Figure 23-10. HS I<sup>2</sup>C Clock Generators Synchronization

### 23.1.2.1.3.11 HS I<sup>2</sup>C External Clock Configuration

Each multimaster HS I<sup>2</sup>C controller is clocked with an independent functional clock (I2Ci\_FCLK) and an interface clock (I2Ci\_ICLK) for interfacing with the L4-PER interconnect. These clocks are provided by the APE PRCM module for I2Ci (where i = 1, 2, 3, 4).

The SYS\_CLK clock provided by the clock generator of the PRCM module is connected to the functional and interface clocks of the HS I<sup>2</sup>C controller I2C5. For detailed information about the module clocking, see [Chapter 3, Power, Reset, and Clock Management](#).

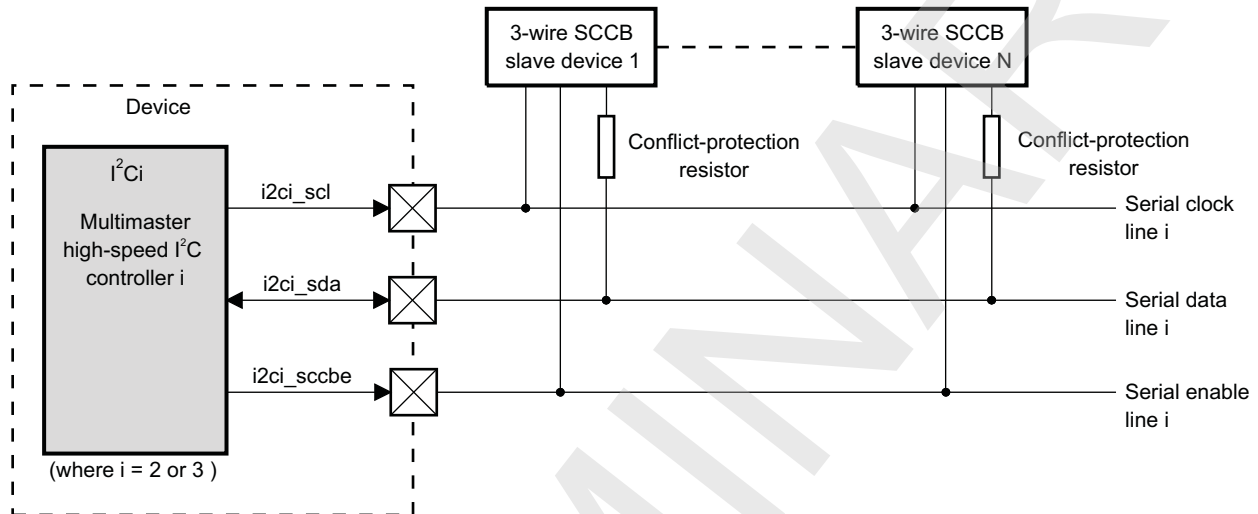

The functional clock is processed by a prescaler block to produce the internal sampling clock. This clock is generated by the I<sup>2</sup>C prescaler block. The prescaler block consists of the I2Ci.I2C\_PSC[7:0] PSC bit field (where i = 1, 2, 3, 4) that is used to divide down the functional clock to obtain an internal sampling clock with a frequency value of I2Ci\_FCLK/(I2Ci.I2C\_PSC[7:0] PSC bit field value + 1, where i = 1, 2, 3, 4).

**NOTE:** The I2Ci.I2C\_PSC[7:0] PSC bit field (where i = 5) of I2C5 is not accessible by software.

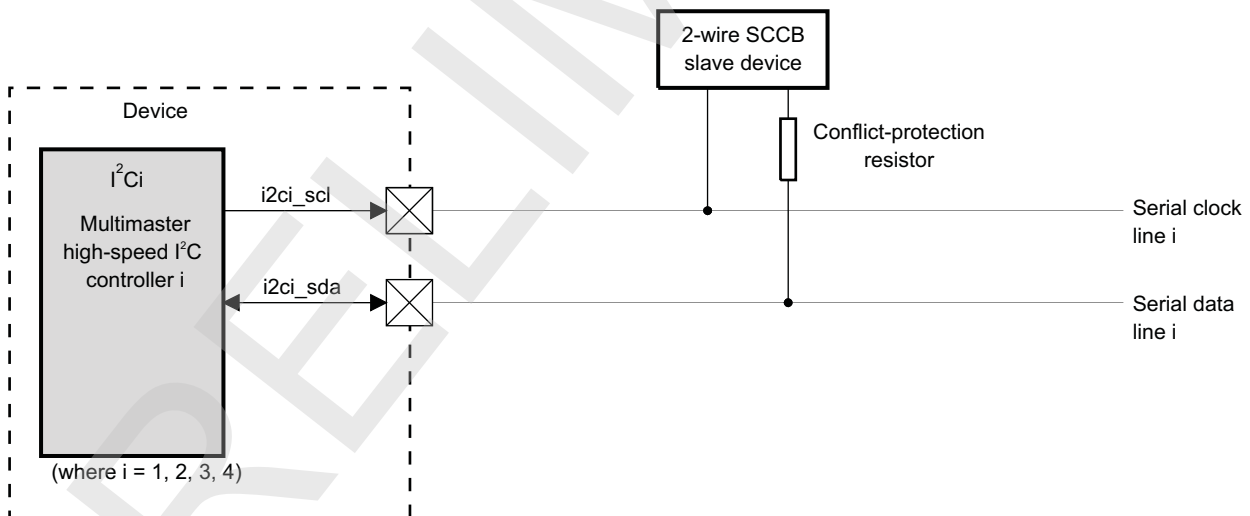

### 23.1.2.2 HS I<sup>2</sup>C in SCCB Mode

The multimaster HS I<sup>2</sup>C controllers support the 2-wire SCCB protocol in master mode as listed in Figure 23-11. Only I2C2 and I2C3 support the 3-wire SCCB protocol in master mode.

**Figure 23-11. HS I<sup>2</sup>C and Typical Connections to SCCB Devices**

(a) Typical connection with 3-wire SCCB devices

(b) Typical connection with 2-wire SCCB devices

I2C-011

**NOTE:** Only one 2-wire SCCB slave device can be connected to the 2-wire SCCB bus.

#### 23.1.2.2.1 HS I<sup>2</sup>C Pins for Typical Connections in SCCB Mode

Figure 23-12 shows the multimaster HS I<sup>2</sup>C controller pins used for typical connections with 3-wire or 2-wire SCCB devices.

Figure 23-12. HS I<sup>2</sup>C Interface Signals in SCCB Mode

(where i = 1, 2, 3, 4 and i2ci\_sccb\_e is not available for I2C1 and I2C4)

I2C-012

23.1.2.2.2 HS I<sup>2</sup>C SCCB Interface Typical Connections

Table 23-2 lists the pins associated with the SCCB interface.

Table 23-2. HS I<sup>2</sup>C Input/Output

Signal	I/O <sup>(1)</sup>	Description	Reset Value <sup>(2)</sup>	I2Ci.I2C_CON[15] I2C_EN bit = 0
i2ci_scl	O	SCCB serial clock line <sup>(3)</sup> . Standard CMOS output buffer.	Hi-Z	High
i2ci_sda	I/O(OD)	SCCB serial data line. Standard CMOS 3-state output buffer. Requires external conflict-protection resistor for each slave device connected to the bus.	Hi-Z	Hi-Z
i2ci_sccb_e <sup>(4)</sup>	O	SCCB enable line. Standard CMOS output buffer.	High	High

<sup>(1)</sup> I = Input; O = Output; OD = Open Drain

<sup>(2)</sup> Hi-Z = High Impedance

<sup>(3)</sup> This output signal is also used as retiming input.

<sup>(4)</sup> This signal is used for the 3-wire SCCB protocol only.

**NOTE:** Because they share the same ball, the i2c2\_sccb\_e and i2c3\_sccb\_e signals are not available at the same time. For detailed information about pin configuration, see Chapter 18, Control Module.

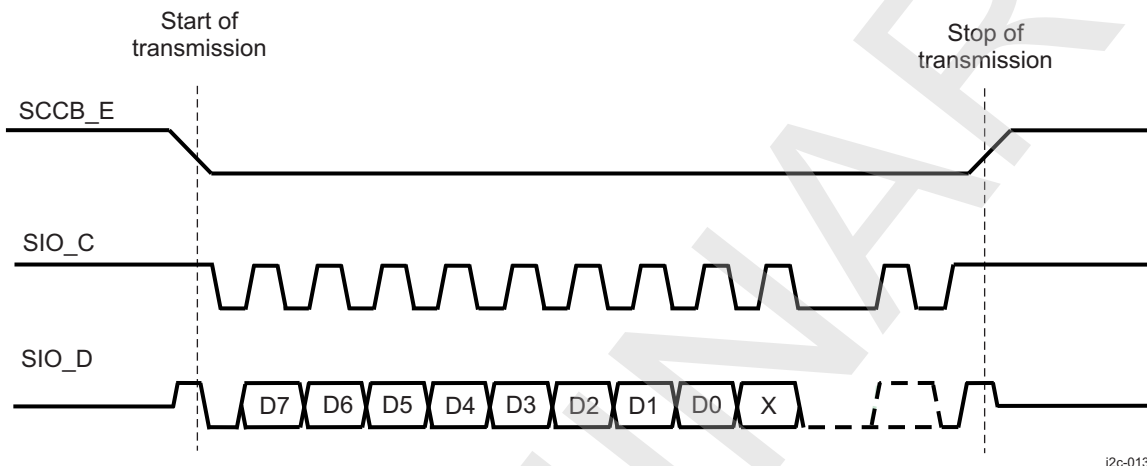

I2C1 and I2C4 do not provide any i2c1\_sccb\_e signal at the chip boundary of the device; thus, these modules do not support the 3-wire SCCB protocol

### 23.1.2.2.3 HS I<sup>2</sup>C SCCB Typical Connection Protocol and Data Format

#### 23.1.2.2.3.1 HS I<sup>2</sup>C SCCB Data Format

If the module is configured in SCCB mode of operation, the data format of transmissions appears as shown in Figure 23-13. For SCCB protocol compatibility I<sup>2</sup>C provides one more signal (SCCB\_E) which acts like a transaction enable signal.

**Figure 23-13. HS I<sup>2</sup>C 3-wire SCCB Transmission Timing Diagram**

**NOTE:** When operating in 2-wire SCCB mode, the i2ci\_sccb\_e signal is not used by the 2-wire SCCB-compliant slave device attached to the 2-wire SCCB bus.

#### 23.1.2.2.3.2 HS I<sup>2</sup>C SCCB Transmission Data Formats

Figure 23-14 describes the data format of the three kinds of transmission.

**Figure 23-14. HS I<sup>2</sup>C SCCB Transmission Data Formats**

R/W: 0 = Write, 1 = Read

X: don't care

NA: ninth bit of a read phase. This bit must be set to 1 by the master device.

I2C-014

The basic element of a data transmission is a phase. A phase contains 9 bits, which consist of an 8-bit sequential data transmission followed by a ninth bit. The ninth bit is a don't-care bit (X) or an NA bit, depending on whether the data transmission is a write or a read. The maximum number of phases that can be included in a transmission is three. The MSB is always asserted first for each phase.

A data transmission is one of three types:

- 3-phase write transmission:

The 3-phase write transmission cycle (see (a) of [Figure 23-14](#)) is a full write operation in which the master can write 1 byte of data to a specific slave(s). The 7-bit slave address in the ID value identifies the specific slave that the master intends to access. The subaddress identifies the register location of the specified slave. The write data contains 8-bit data that the master intends to write over the content of this specific address. The ninth bit of each of the three phases is a don't-care bit (X bit).

- 2-phase write transmission:

The 2-phase write transmission cycle is followed by a 2-phase read transmission cycle (see below). The purpose of issuing a 2-phase write transmission cycle (see (b) of [Figure 23-14](#)) is to identify the subaddress of some specific slave from which the master intends to read data for the following 2-phase read transmission cycle. The ninth bit of each phase is a don't-care bit (X bit).

- 2-phase read transmission:

Either a 3-phase or a 2-phase write transmission cycle must be asserted ahead of a 2-phase read transmission cycle. The 2-phase read transmission cycle (see (c) of [Figure 23-14](#)) has no ability to identify the subaddress. The 2-phase write transmission cycle contains read data of 8 bits and a ninth don't-care bit or NA bit. The master must drive the NA bit at logical 1.

In each transmission type, phase 1 (the 7-bit slave address of the ID value) is asserted by the master to identify the selected slave to which the data is read or written. Each slave has a unique 7-bit slave address. The 7-bit slave address of the ID value comprises 7 bits, from bit 7 to bit 1, that can identify up to 128 slaves. The eighth bit, bit 0, is the read/write selector bit that specifies the transmission direction of the current cycle. A logical 0 represents a write cycle and a logical 1 represents a read cycle. The ninth bit of phase 1 is a don't-care bit (X bit).

Phase 2 (subaddress/read data) is asserted by the master (subaddress) or the slave(s) (read data). A phase 2 transmission asserted by the master identifies the subaddress of the slave(s) the master intends to access. A phase 2 transmission asserted by the slave(s) indicates the read data that the master will receive. The slave(s) recognize the subaddress of this read data according to the previous 3-phase or 2-phase write transmission cycle. The ninth bit is defined as a don't-care bit (X bit) when the master asserts phase 2. The ninth bit is defined as an NA bit when the slave(s) asserts the phase 2 transmission. The master is responsible for a logical 1 during the period of the NA bit.

Phase 3 (write data) is asserted only by the master. This phase contains the data the master intends to write to the slave(s). Because the master asserts the transmission, the ninth bit of the phase 3 transmission is defined as a don't-care bit (X bit).

---

**NOTE:** A multimaster HS I<sup>2</sup>C controller configured in SCCB mode can perform two operations:

- Writing a single byte to an SCCB slave device by using the 3-phase write transmission cycle
  - Reading a single byte from an SCCB slave device by using the 2-phase write transmission cycle followed by the 2-phase read transmission cycle
- 

### 23.1.2.2.3.3 HS I<sup>2</sup>C Data Validity

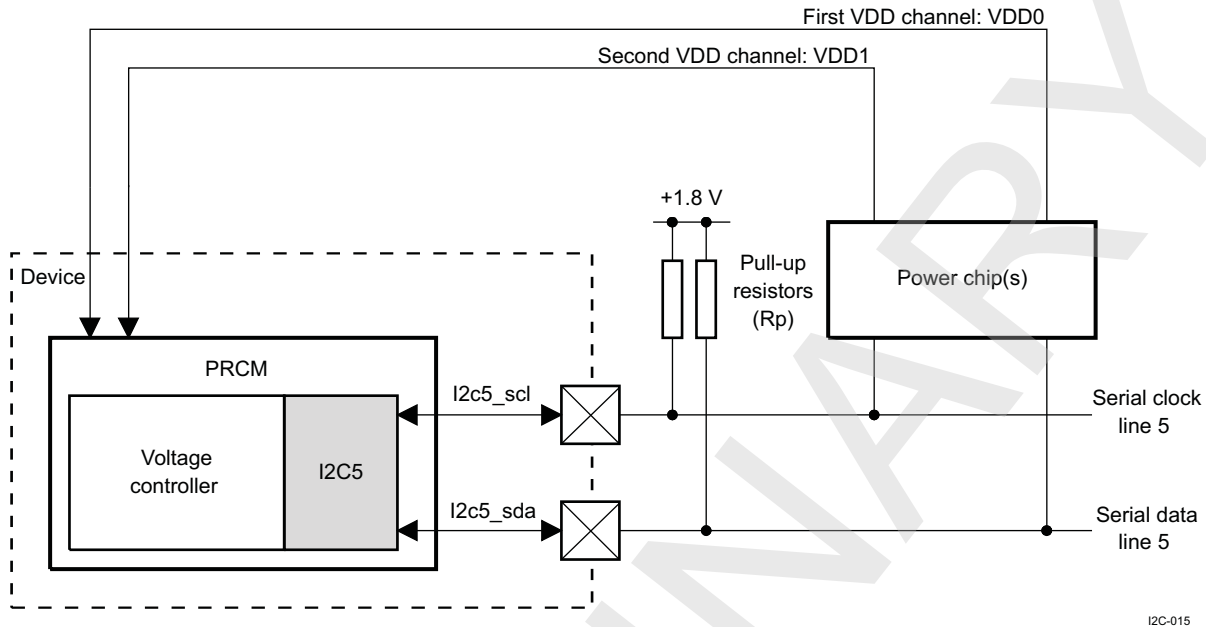

The data validity is the same as described in [Section 23.1.2.1.3.2, I<sup>2</sup>C Data Validity](#).

### 23.1.2.2.3.4 HS I<sup>2</sup>C S and P Conditions

The S and P conditions are the same as described in [Section 23.1.2.1.3.3, I<sup>2</sup>C Start and Stop Conditions](#).

## 23.1.2.3 HS I<sup>2</sup>C for Communication With Power Chip(s)

[Figure 23-15](#) shows a typical connection between the master transmitter HS I<sup>2</sup>C controller I2C5 of the device and external power chip(s).

**Figure 23-15. HS I<sup>2</sup>C and Typical Connection Between the HS I<sup>2</sup>C and Power Chip(s)**

I2C-015

### 23.1.2.3.1 HS I<sup>2</sup>C I2C5 Pins for Typical Connections

Figure 23-16 shows the HS I<sup>2</sup>C controller I2C5 pins used for typical connections with power chips.

**Figure 23-16. HS I<sup>2</sup>C I2C5 Interface Signals**

I2C-016

### 23.1.2.3.2 HS I<sup>2</sup>C I2C5 Interface Typical Connections

The master transmitter HS I<sup>2</sup>C controller I2C5 interfaces between the and external power chip(s) for voltage control. This module is always configured as an I<sup>2</sup>C master transmitter; it does not support the SCCB protocol.

Table 23-3 lists the pins associated with the I<sup>2</sup>C interface of the HS I<sup>2</sup>C controller I2C5 of the device.

**Table 23-3. HS I<sup>2</sup>C Input/Output Description**

Signal	I/O <sup>(1)</sup>	Description	Reset Value
i2c5_scl	I/O(OD)	I <sup>2</sup> C serial clock line <sup>(2)</sup> . Open-drain output buffer. Requires external Rp.	1
i2c5_sda	I/O(OD)	I <sup>2</sup> C serial data line. Open-drain output buffer. Requires external Rp.	1

<sup>(1)</sup> I = Input; O = Output; OD = Open Drain

<sup>(2)</sup> This signal is also used as re-timing input.

### **23.1.2.3.3 HS I<sup>2</sup>C Typical Connections Protocol and Data Format for I2C5**

#### **23.1.2.3.3.1 HS I<sup>2</sup>C Serial Data Format for I2C5**

The serial data format is the same as described in [Section 23.1.2.1.3.1](#), *I<sup>2</sup>C Serial Data Format*.

#### **23.1.2.3.3.2 HS I<sup>2</sup>C Data Validity for I2C5**

The data validity is the same as described in [Section 23.1.2.1.3.2](#), *I<sup>2</sup>C Data Validity*.

#### **23.1.2.3.3.3 HS I<sup>2</sup>C S and P Conditions for I2C5**

The S and P conditions are the same as described in [Section 23.1.2.1.3.3](#), *I<sup>2</sup>C Start and Stop Conditions*.

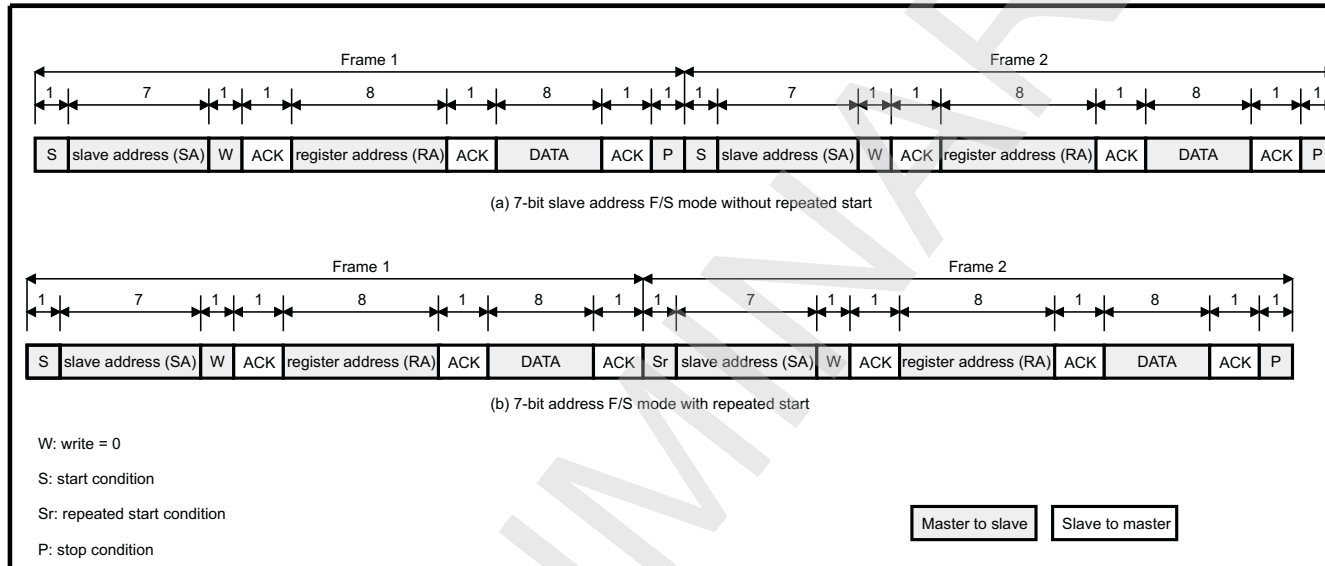

#### **23.1.2.3.3.4 HS I<sup>2</sup>C Addressing for I2C5**

The master transmitter HS I<sup>2</sup>C controller I2C5 supports only the 7-bit addressing mode. For each frame, the master writes the 8-bit value (DATA) in the register specified by the 8-bit register address (RA) of the slave addressed by the slave address (SA).

23.1.2.3.3.4.1 HS I<sup>2</sup>C Data Transfer Format in F/S Mode

Figure 23-17 shows the I<sup>2</sup>C data transfer format in F/S mode for I2C5.

Figure 23-17. HS I<sup>2</sup>C Data Transfer Format in F/S Mode for I2C5

I2C-017

23.1.2.3.3.4.2 Data Transfer Format in HS Mode

Figure 23-18 shows the I<sup>2</sup>C data transfer format in HS mode for I2C5.

Figure 23-18. HS I<sup>2</sup>C Data Transfer Format in HS Mode for the I2C5 Module

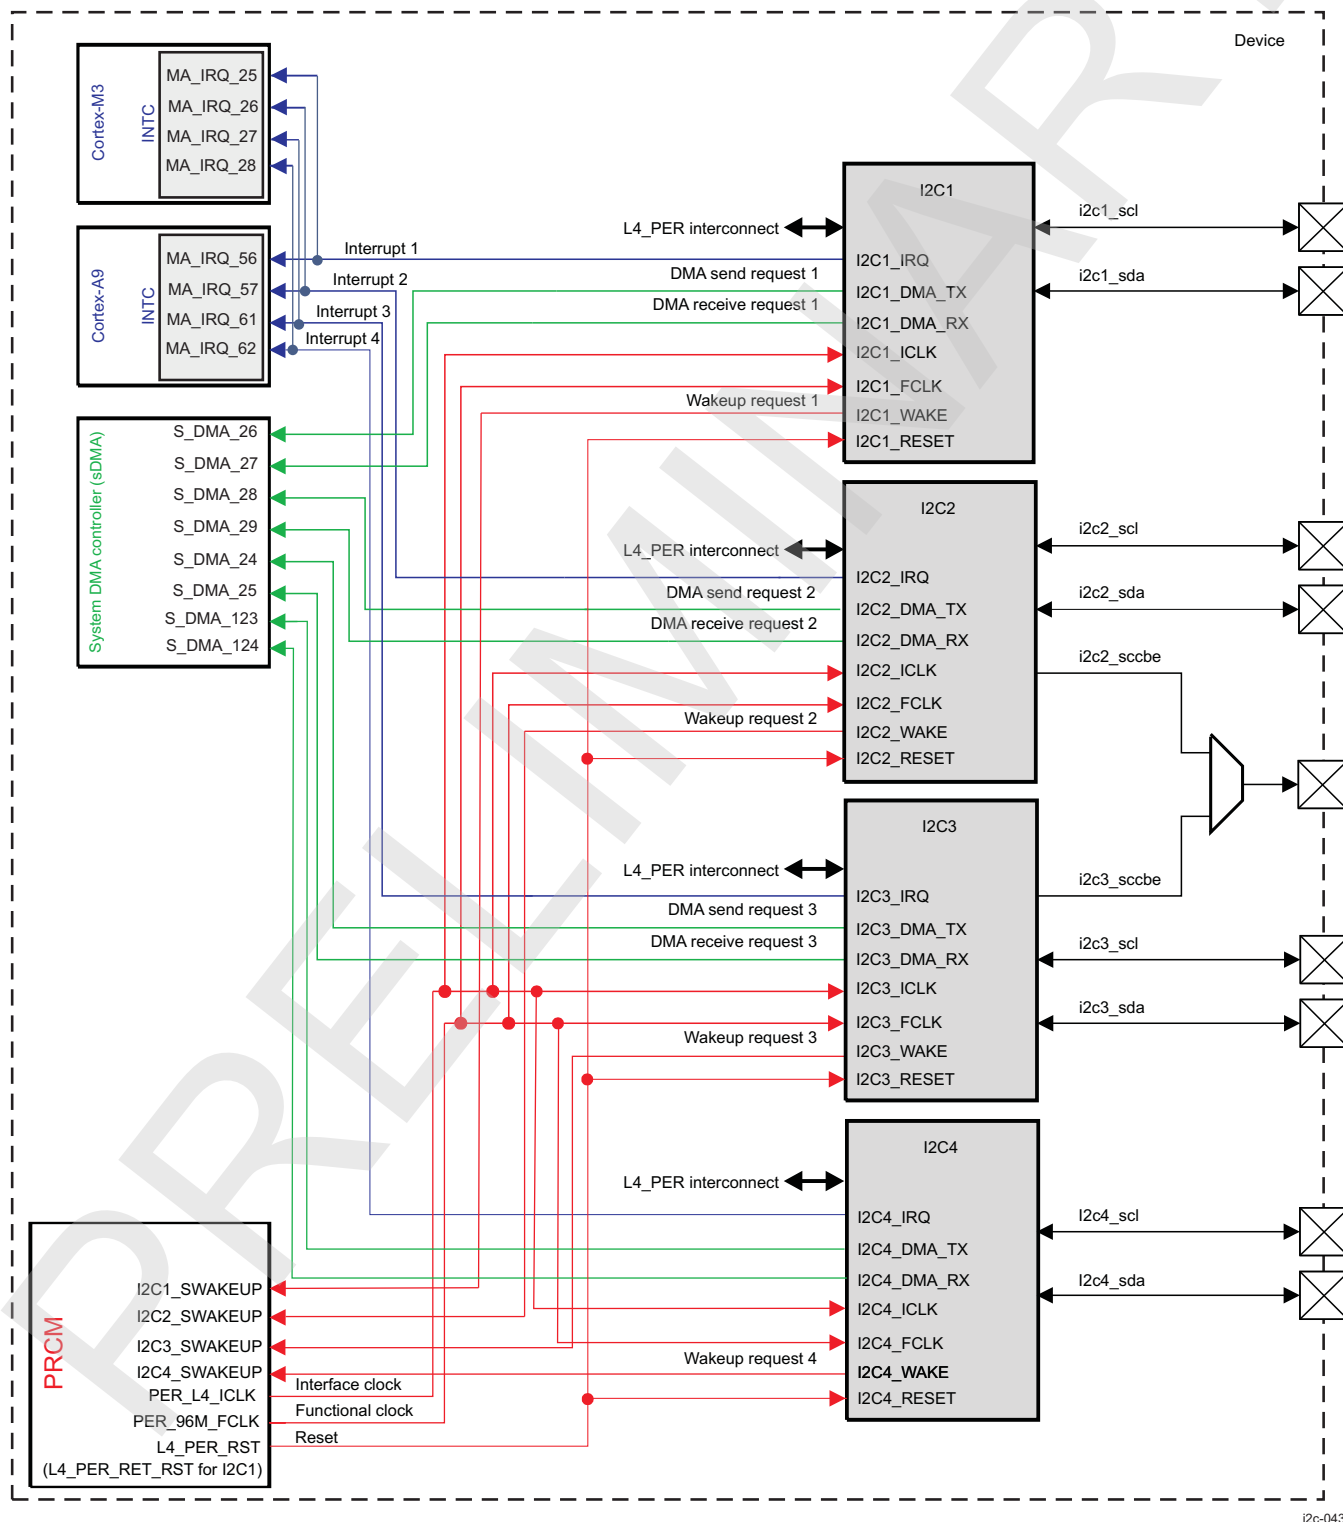

I2C-018

### 23.1.3 HS I<sup>2</sup>C Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 23-19 shows the integration of the four HS I<sup>2</sup>C controllers in the device.

Figure 23-19. HS I<sup>2</sup>C Integration

i2c-043

Figure 23-20 shows HS I<sup>2</sup>C integration of I2C5 inside the PRCM module.

Figure 23-20. HS I<sup>2</sup>C I2C5 Integration

**NOTE:** For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.7, Power Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 23-4 through Table 23-6 summarize the integration of the module in the device.

Table 23-4. HS I<sup>2</sup>C Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
I2C1	PD_L4_PER	L4_PER
I2C2	PD_L4_PER	L4_PER
I2C3	PD_L4_PER	L4_PER
I2C4	PD_L4_PER	L4_PER

Table 23-5. HS I<sup>2</sup>C Clocks and Resets

Module Instance	Destination Signal Name	Source Signal Name	Clocks	
			Source	Description
I2C1	I2C1_ICLK	PER_L4_ICLK	PRCM	I2C1 interface clock
	I2C1_FCLK	PER_96M_FCLK	PRCM	I2C1 functional clock
I2C2	I2C2_ICLK	PER_L4_ICLK	PRCM	I2C2 interface clock
	I2C2_FCLK	PER_96M_FCLK	PRCM	I2C2 functional clock
I2C3	I2C3_ICLK	PER_L4_ICLK	PRCM	I2C3 interface clock

<b>Resets</b>				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
I2C1	I2C1_RESET	L4_PER_RET_RST	PRCM	I2C1 reset
I2C2	I2C2_RESET	L4_PER_RST	PRCM	I2C2 reset
I2C3	I2C3_RESET	L4_PER_RST	PRCM	I2C3 reset
I2C4	I2C4_RESET	L4_PER_RST	PRCM	I2C4 reset

**Table 23-6. HS I<sup>2</sup>C Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
I2C1	I2C1_IRQ	MA_IRQ_56	Cortex-A9 INTC	I2C1 interrupt request
	I2C1_IRQ	MM_IRQ_25	Cortex-M3 INTC	I2C1 interrupt request
I2C2	I2C2_IRQ	MA_IRQ_57	Cortex-A9 INTC	I2C2 interrupt request
	I2C2_IRQ	MM_IRQ_26	Cortex-M3 INTC	I2C2 interrupt request
I2C3	I2C3_IRQ	MA_IRQ_61	Cortex-A9 INTC	I2C3 interrupt request
	I2C3_IRQ	MM_IRQ_27	Cortex-M3 INTC	I2C3 interrupt request
I2C4	I2C4_IRQ	MA_IRQ_62	Cortex-A9 INTC	I2C4 interrupt request
	I2C4_IRQ	MM_IRQ_28	Cortex-M3 INTC	I2C4 interrupt request
DMA Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
I2C1	I2C1_DMA_TX	S_DMA_26	sDMA	I2C1 DMA transmit request
	I2C1_DMA_RX	S_DMA_27	sDMA	I2C1 DMA receive request
I2C2	I2C2_DMA_TX	S_DMA_28	sDMA	I2C2 DMA transmit request
	I2C2_DMA_RX	S_DMA_29	sDMA	I2C2 DMA receive request
I2C3	I2C3_DMA_TX	S_DMA_24	sDMA	I2C3 DMA transmit request
	I2C3_DMA_RX	S_DMA_25	sDMA	I2C3 DMA receive request
I2C4	I2C4_DMA_TX	S_DMA_123	sDMA	I2C4 DMA transmit request
	I2C4_DMA_RX	S_DMA_124	sDMA	I2C4 DMA receive request

**NOTE:**

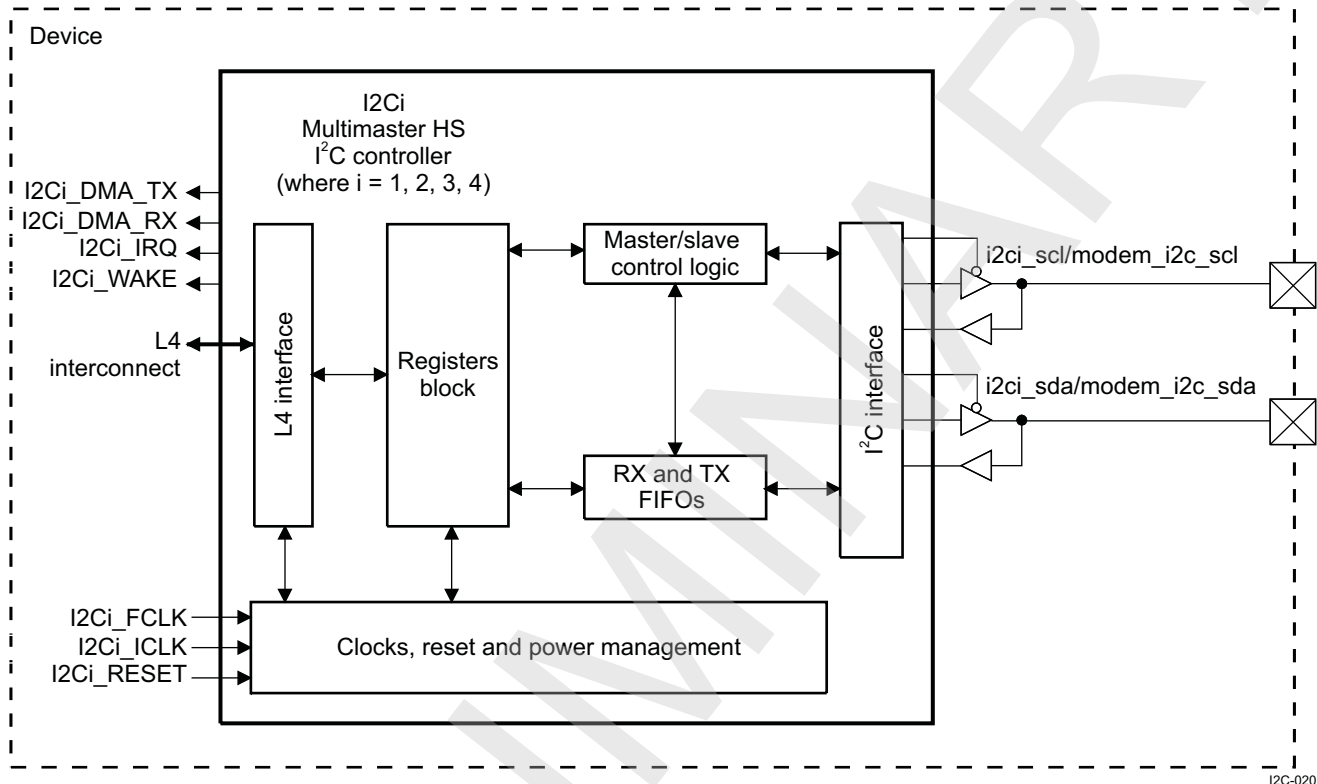

- For a description of interrupt source, see [Table 23-12, Interrupt Requests](#).
- For a description of DMA source, see [Table 23-13, DMA Requests](#).

### 23.1.4 HS I<sup>2</sup>C Functional Description

#### 23.1.4.1 HS I<sup>2</sup>C Block Diagram

Figure 23-21 is the multimaster I<sup>2</sup>C HS controller block diagram.

Figure 23-21. HS I<sup>2</sup>C Block Diagram

The five multimaster HS I<sup>2</sup>C controllers can be configured in F/S I<sup>2</sup>C mode, HS I<sup>2</sup>C mode, or SCCB mode. The operation mode is selected by configuring the I2Ci.I2C\_CON[13:12] OPMODE bit field. Table 23-7 lists the available operation modes.

**NOTE:** The fifth master transmitter HS I<sup>2</sup>C interface (I2C5) in the power, reset, and clock management (PRCM) could also be configured in High-speed mode.

Table 23-7. HS I<sup>2</sup>C Operation Mode Selection

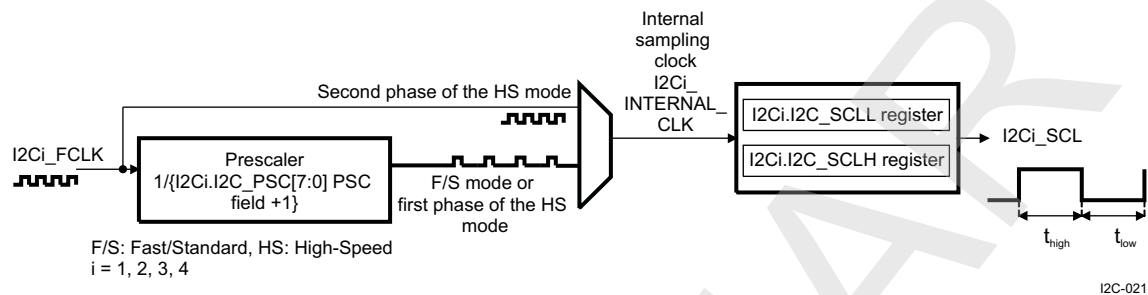

Operation Mode	Value of I2Ci.I2C_CON[13:12] OPMODE Bit Field
F/S I <sup>2</sup> C	0x0
HS I <sup>2</sup> C	0x1
SCCB	0x2
Reserved (not used)	0x3

### 23.1.4.2 HS I<sup>2</sup>C Clocks

#### 23.1.4.2.1 HS I<sup>2</sup>C Clocking

Figure 23-22 shows the I<sup>2</sup>C clock generation of the HS I<sup>2</sup>C controllers.

**Figure 23-22. HS I<sup>2</sup>C Clock Generation**

Each multimaster HS I<sup>2</sup>C controller uses the I2Ci\_FCLK functional clock in the PRCM module. The internal sampling clock I2Ci\_INTERNAL\_CLK is generated by dividing the functional clock by (the I2Ci.I2C\_PSC[7:0] PSC bit field value + 1) in F/S mode, in SCCB mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the I2Ci\_SCL signal is determined by the I2Ci.I2C\_SCLL[7:0] SCLL bit field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I2Ci.I2C\_SCLL[15:8] HSSCLL bit field in the second phase of HS mode.

The high time of the I2Ci\_SCL signal is determined by the I2Ci.I2C\_SCLH[7:0] SCLH bit field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I2Ci.I2C\_SCLH[15:8] HSSCLH bit field in the second phase of HS mode.

Table 23-8 lists the  $t_{LOW}$  and  $t_{high}$  values in master mode only (in slave mode, the I<sup>2</sup>C controller does not generate the I<sup>2</sup>C clock).

**Table 23-8. HS I<sup>2</sup>C  $t_{LOW}$  and  $t_{high}$  Values of the I<sup>2</sup>C Clock**

Mode	I2Ci_INTERNAL_CLK	$t_{LOW}$	$t_{high}$
F/S, SCCB, or HS first phase	I2Ci_FCLK / (I2Ci.I2C_PSC[7:0] PSC bit field + 1)	(I2Ci.I2C_SCLL[7:0] SCLL bit field value + 7) x I2Ci_INTERNAL_CLK period	(I2Ci.I2C_SCLH[7:0] SCLH bit field value + 5) x I2Ci_INTERNAL_CLK period
HS second phase	I2Ci_FCLK	(I2Ci.I2C_SCLL[15:8] HSSCLL bit field value + 7) x I2Ci_INTERNAL_CLK period	(I2Ci.I2C_SCLH[15:8] HSSCLH bit field value + 5) x I2Ci_INTERNAL_CLK period

**NOTE:** For HS mode, the I2Ci.I2C\_SCLL[15:8] HSSCLL and I2Ci.I2C\_SCLL[7:0] SCLL bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, the I2Ci.I2C\_SCLH[15:8] HSSCLH and I2Ci.I2C\_SCLH[7:0] SCLH bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

**NOTE:** The equations in Table 23-8 give the SCL timing values for SCLL/SCLH/HSSCLL/HSSCLH at HS I<sup>2</sup>C controller outputs. Actual  $t_{low}$  and  $t_{high}$  periods may vary depending on the board (the load capacitance on the SCL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board

### CAUTION

During active mode (I2Ci.I2C\_CON[15] I2C\_EN bit is set to 1), make no changes to the I2Ci.I2C\_SCLL and I2Ci.I2C\_SCLH registers. Changes may result in unpredictable behavior.

**NOTE:** Each multimaster HS I<sup>2</sup>C controller can be used with an internal secondary pullup. This pullup is mandatory when the I<sup>2</sup>C controller is configured in HS mode for a bit rate of 3.4 Mbps, and the bus line capacitance exceeds 45 pF. Pullups can be programmed through:

- CCONTROL\_I2C\_0[0] I2C1\_SCL\_PULLUPRESX bit or CCONTROL\_I2C\_0[16] I2C1\_SDA\_PULLUPRESX bit for I2C1
- CONTROL\_I2C\_0[4] I2C2\_SCL\_PULLUPRESX bit or CONTROL\_I2C\_0[20] I2C2\_SDA\_PULLUPRESX bit for I2C2
- CONTROL\_I2C\_0[8] I2C3\_SCL\_PULLUPRESX bit or CONTROL\_I2C\_0[24] I2C3\_SDA\_PULLUPRESX bit for I2C3
- CONTROL\_I2C\_0[12] I2C4\_SCL\_PULLUPRESX bit or CONTROL\_I2C\_0[28] I2C4\_SDA\_PULLUPRESX bit for I2C4

The maximum bit rate specified by the SCCB specifications is 100 Kbps.

For more information see [Section 18.4.12.6.9](#), *I2Cx I/Os Group Pullupresx Controls and Load Range Settings*.

Table 23-9 lists the register values for obtaining the maximum I<sup>2</sup>C bit rates and the maximum period of the filtered spikes in F/S mode and HS mode.

**Table 23-9. HS I<sup>2</sup>C Register Values for Maximum I<sup>2</sup>C Bit Rates in I<sup>2</sup>C F/S, I<sup>2</sup>C HS, and SCCB Modes<sup>(1)</sup>**

	I <sup>2</sup> C Mode for I2Ci, where i = 1, 2, 3, 4				Description	SCCB Mode for I2Ci, where i = 2, 3		I <sup>2</sup> C Mode for I2C5  Fast and High-Speed Mode	
	Standard Mode	Fast Mode	Fast Mode+	High-Speed Mode					
I2Ci_FCLK frequency (MHz)	96					96		12, 16.8, 19.2, 26, or 38.4	SYS_CLK clock frequency
<b>I2Ci.I2C_PSC[7:0] PSC field value</b>	<b>23</b>	<b>9</b>	<b>5</b>	<b>1</b>	Prescaler value for F/S and HS modes	<b>4</b>	Prescaler value for SCCB mode	Not accessible by software

HS mode maximum bit rate (Mbps)				3.31	HS mode maximum bit rate			0.8, 1.28, 1.73, 2.56, 3.31	HS mode maximum bit rate according to the corresponding SYS_CLK clock frequency
Maximum filter period (ns)				10				10	

<sup>(1)</sup> Programmable fields are in bold.

---

**NOTE:** This table presents informative values only for the configuration parameters and the I<sup>2</sup>C bus performance obtained according to these values. The delays added by the analog pads are not considered in these figures.

---

---

**NOTE:** I<sup>2</sup>Ci\_INTERNAL\_CLK freq = SYS\_CLK / PSC  
 F/S filter period = 1 / 2Ci\_INTERNAL\_CLK  
 HS filter period = 1 / SYS\_CLK freq  
 HS bit rate = SYS\_CLK freq / (HSSCLL + 7 + HSSCLH + 5)  
 F/S bit rate = 2Ci\_INTERNAL\_CLK / (SCLL + 7 + SCLH + 5)

---

PRELIMINARY

### 23.1.4.2.2 HS I<sup>2</sup>C Automatic Blocking of the I<sup>2</sup>C Clock Feature (I<sup>2</sup>C Mode Only)

This feature offers the possibility for the LH to command the blocking of the I<sup>2</sup>C clock after the slave addressing phase, when the I<sup>2</sup>C controller is addressed by an external master device using a certain Own Address.

The release of the I<sup>2</sup>C clock can be performed independently for each Own Address (I2Ci.I2C\_OA<sub>i</sub>, where i = 1, 2, 3, 4 and I2Ci.I2C\_OAx registers, where x = 1, 2, 3) by deasserting the corresponding bit in the I2Ci.I2C\_SBLOCK register.

### 23.1.4.3 HS I<sup>2</sup>C Software Reset

Each multimaster HS I<sup>2</sup>C controller supports the software reset by accessing the I2Ci.I2C\_SYSC[1] SRST bit (1: reset; 0: normal mode).

The software reset status can be checked by accessing the I2Ci.I2C\_SYSS[0] RDONE bit (1: reset is done; 0: reset is ongoing).

To perform a software reset:

1. Ensure that the module is disabled (clear the I2Ci.I2C\_CON[15] I2C\_EN bit to 0).
2. Set the I2Ci.I2C\_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2Ci.I2C\_CON[15] I2C\_EN bit to 1.
4. Check the I2Ci.I2C\_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

---

**NOTE:** The I2Ci.I2C\_CON[15] I2C\_EN bit can hold the functional clock domain of the multimaster HS I<sup>2</sup>C controller in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I<sup>2</sup>C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2Ci.I2C\_CON[15] I2C\_EN bit must be set to 1 to enable the functional part of the I<sup>2</sup>C controller.

The I2Ci.I2C\_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2Ci.I2C\_CON[15] I2C\_EN bit to 1.

---

### 23.1.4.4 HS I<sup>2</sup>C Power Management

Table 23-10 describes power-management features available for the multimaster HS I<sup>2</sup>C controllers.

**NOTE:**

- For information about source clock gating and sleep/wake-up transitions description, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
  - For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
- 

**Table 23-10. HS I<sup>2</sup>C Local Power-Management Features**

Feature	Registers	Description
Clock auto gating	I2Ci.I2C_SYSC[0] AUTOIDLE	This bit allows a local power optimization inside the module
Slave idle modes	I2Ci.I2C_SYSC[4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wake-up-capable modes are available.
Clock activity	I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY	For configuration details, see Table 23-11.
Global wake-up enable	I2Ci.I2C_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.

**NOTE:** The voltage controllers, in which the HS I<sup>2</sup>C controller I2C5 are implemented, have no idle request/acknowledge mechanism. The idle modes for the voltage controllers are directly managed by the PRCM module.

**Table 23-11. HS I<sup>2</sup>C Clock Activity Settings**

I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY	Clock State When Module is in IDLE State		Features Available/Unavailable When Module is in IDLE State
	I2Ci_ICLK	I2C_FCLK	
00	OFF	OFF	Both clocks are disabled
10	OFF	ON	Interface clock is disabled; functional clock is enabled
01	ON	OFF	Functional clock is disabled; interface clock is enabled
11	ON	ON	Both clocks are enabled

**CAUTION**

The PRCM module has no hardware means of reading the settings of CLOCKACTIVITY. Thus, software must ensure consistent programming between the I2C CLOCKACTIVITY and I2C clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

**23.1.4.5 HS I<sup>2</sup>C Interrupt Requests**

[Table 23-12](#) lists the event flags, and their mask, that can cause module interrupts.

**Table 23-12. HS I<sup>2</sup>C Events**

Event Flag	Event Mask	Event Unmask	Map to	Description
I2Ci.I2C_IRQSTATUS[0] AL	I2Ci.I2C_IRQENABLE_SET[0] AL_IE	I2Ci.I2C_IRQENABLE_C LR[0] AL_IE	I2Ci_IRQ	Arbitration lost IRQ enabled status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to the MPU subsystem. During reads, it always returns 0.
I2Ci.I2C_IRQSTATUS[1] NACK	I2Ci.I2C_IRQENABLE_SET[1] NACK_IE	I2Ci.I2C_IRQENABLE_C LR[1] NACK_IE	I2Ci_IRQ	No acknowledgment IRQ enabled status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPU subsystem. Write 1 to clear this bit.
I2Ci.I2C_IRQSTATUS[2] ARDY	I2Ci.I2C_IRQENABLE_SET[2] ARDY_IE	I2Ci.I2C_IRQENABLE_C LR[2] ARDY_IE	I2Ci_IRQ	Register access ready IRQ enabled status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPU subsystem. Write 1 to clear.
I2Ci.I2C_IRQSTATUS[3] RRDY	I2Ci.I2C_IRQENABLE_SET[3] RRDY_IE	I2Ci.I2C_IRQENABLE_C LR[3] RRDY_IE	I2Ci_IRQ	Receive data ready IRQ enabled status. Set to 1 by core when receiver mode, a new data is able to be read. When set to 1 by core, an interrupt is signaled to MPU subsystem. Write 1 to clear.

**Table 23-12. HS I<sup>2</sup>C Events (continued)**

Event Flag	Event Mask	Event Unmask	Map to	Description
I2Ci.I2C_IRQSTATUS[4] XRDY	I2Ci.I2C_IRQENABLE_SET[4] XRDY_IE	I2Ci.I2C_IRQENABLE_C LR[4] XRDY_IE	I2Ci_IRQ	Transmit data ready IRQ enabled status. Set to 1 by core when transmitter and when new data is requested. When set to 1 by core, an interrupt is signaled to MPU subsystem. Write 1 to clear.
I2Ci.I2C_IRQSTATUS[5] GC	I2Ci.I2C_IRQENABLE_SET[5] GC_IE	I2Ci.I2C_IRQENABLE_C LR[5] GC_IE	I2Ci_IRQ	General call IRQ enabled status. Set to 1 by core when General call address detected and interrupt signaled to MPU subsystem. Write 1 to clear.
I2Ci.I2C_IRQSTATUS[6] STC	I2Ci.I2C_IRQENABLE_SET[6] STC_IE	I2Ci.I2C_IRQENABLE_C LR[6] STC_IE	I2Ci_IRQ	Start Condition IRQ enabled status.
I2Ci.I2C_IRQSTATUS[7] AERR	I2Ci.I2C_IRQENABLE_SET[7] AERR_IE	I2Ci.I2C_IRQENABLE_C LR[7] AERR_IE	I2Ci_IRQ	Access Error IRQ enabled status.
I2Ci.I2C_IRQSTATUS[8] BF	I2Ci.I2C_IRQENABLE_SET[8] BF_IE	I2Ci.I2C_IRQENABLE_C LR[8] BF_IE	I2Ci_IRQ	Access Error IRQ enabled status.
I2Ci.I2C_IRQSTATUS[9] AAS	I2Ci.I2C_IRQENABLE_SET[9] AAS_IE	I2Ci.I2C_IRQENABLE_C LR[9] AAS_IE	I2Ci_IRQ	Address recognized as slave IRQ enabled status.
I2Ci.I2C_IRQSTATUS[10] XUDF	I2Ci.I2C_IRQENABLE_SET[1 0] XUDF_IE	I2Ci.I2C_IRQENABLE_C LR[10] XUDF_IE	I2Ci_IRQ	Transmit underflow enabled status. Writing into this bit has no effect.
I2Ci.I2C_IRQSTATUS[11] ROVR	I2Ci.I2C_IRQENABLE_SET[1 1] ROVR_IE	I2Ci.I2C_IRQENABLE_C LR[11] ROVR_IE	I2Ci_IRQ	Receive overrun enabled status. Writing into this bit has no effect.
I2Ci.I2C_IRQSTATUS[12] BB	I2Ci.I2C_IRQENABLE_SET[1 2] BB_IE	I2Ci.I2C_IRQENABLE_C LR[12] BB_IE	I2Ci_IRQ	Bus busy enabled status. Writing into this bit has no effect.
I2Ci.I2C_IRQSTATUS[13] RDR	I2Ci.I2C_IRQENABLE_SET[1 3] RDR_IE	I2Ci.I2C_IRQENABLE_C LR[13] RDR_IE	I2Ci_IRQ	Receive draining IRQ enabled status.
I2Ci.I2C_IRQSTATUS[14] XDR	I2Ci.I2C_IRQENABLE_SET[1 4] XDR_IE	I2Ci.I2C_IRQENABLE_C LR[14] XDR_IE	I2Ci_IRQ	Transmit draining IRQ enabled status.

#### 23.1.4.6 HS I<sup>2</sup>C DMA Requests

Each multimaster HS I<sup>2</sup>C controller can generate two DMA requests to the system DMA (sDMA) controller. [Table 23-13](#) lists the DMA requests with mapping on the sDMA controller. For information about DMA generation, see [Section 23.1.4.8.3, HS I<sup>2</sup>C FIFO DMA Mode \(I<sup>2</sup>C Mode Only\)](#).

**Table 23-13. HS I<sup>2</sup>C DMA Requests**

Name	Source	Destination	Description
I2C1_DMA_TX	I2C1	S_DMA_26	I2C1 DMA write request to inform the sDMA to write new data in the I2C1.I2C_DATA[7:0] register
I2C1_DMA_RX	I2C1	S_DMA_27	I2C1 DMA read request to inform the sDMA to read the data in the I2C1.I2C_DATA[7:0] register
I2C2_DMA_TX	I2C2	S_DMA_28	I2C2 DMA write request to inform the sDMA to write new data in the I2C2.I2C_DATA[7:0] register
I2C2_DMA_RX	I2C2	S_DMA_29	I2C2 DMA read request to inform the sDMA to read the data in the I2C2.I2C_DATA[7:0] register
I2C3_DMA_TX	I2C3	S_DMA_24	I2C3 DMA write request to inform the sDMA to write new data in the I2C3.I2C_DATA[7:0] register
I2C3_DMA_RX	I2C3	S_DMA_25	I2C3 DMA read request to inform the sDMA to read the data in the I2C3.I2C_DATA[7:0] register

**Table 23-13. HS I<sup>2</sup>C DMA Requests (continued)**

Name	Source	Destination	Description
I2C4_DMA_TX	I2C4	S_DMA_123	I2C4 DMA write request to inform the sDMA to write new data in the I2C4.I2C_DATA[7:0] register
I2C4_DMA_RX	I2C4	S_DMA_124	I2C4 DMA read request to inform the sDMA to read the data in the I2C4.I2C_DATA[7:0] register

**NOTE:** The HS I<sup>2</sup>C controller I2C5 does not generate any DMA requests.

**23.1.4.7 HS I<sup>2</sup>C Programmable Multislave Channel Feature (I<sup>2</sup>C Mode Only)**

This feature allows each multimaster HS I<sup>2</sup>C controller to be addressed using four separate Own Addresses configured in the I2Ci.I2C\_OA and I2Ci.I2C\_OAx registers (where x = 1, 2, 3). An additional register (I2Ci.I2C\_ACTOA) is used to indicate to the LH which address is used by the external master to communicate with the I<sup>2</sup>C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2Ci.I2C\_CON[7] XOA, I2Ci.I2C\_CON[6] XOA1, I2Ci.I2C\_CON[5] XOA2, or I2Ci.I2C\_CON[4] XOA3).

**23.1.4.8 HS I<sup>2</sup>C FIFO Management**

Each multimaster HS I<sup>2</sup>C controller implements two internal 8-bit FIFOs, the RX and TX FIFOs.

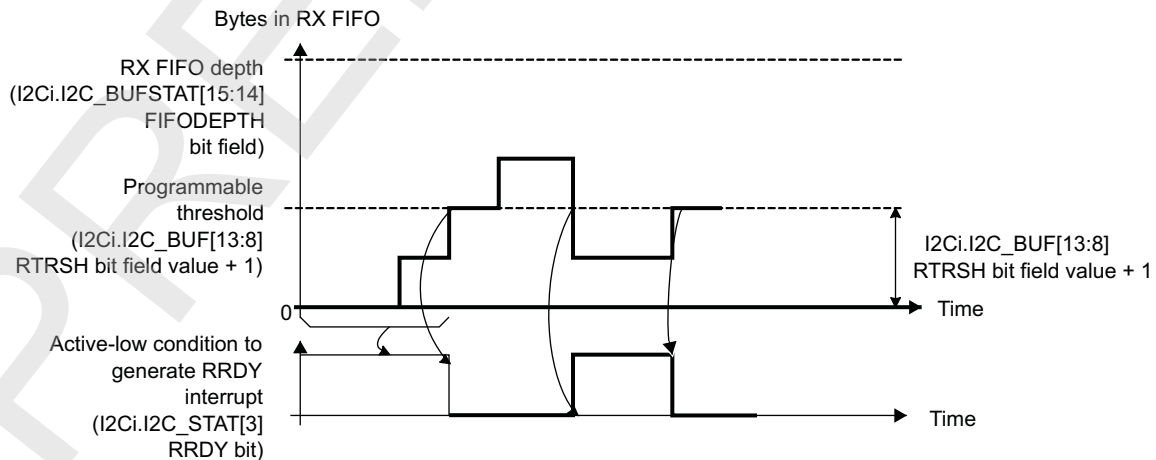

The depth of the RX and TX FIFOs can be checked by reading the I2Ci.I2C\_BUFSTAT[15:14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

**23.1.4.8.1 HS I<sup>2</sup>C FIFO Interrupt Mode**

In FIFO interrupt mode (relevant interrupts enabled by the I2Ci.I2C\_IE register), an interrupt signal informs the processor of the receiver and transmitter status. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2Ci.I2C\_BUF[13:8] RTRSH bit field value + 1 for the RX FIFO or the I2Ci.I2C\_BUF[5:0] TXTRSH bit field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I<sup>2</sup>C controller in receive mode and/or from any source to the I<sup>2</sup>C controller FIFO in transmit mode).

Figure 23-23 and Figure 23-24 show receive and transmit operations, respectively, from a FIFO management point of view.

**Figure 23-23. HS I<sup>2</sup>C Receive FIFO Interrupt Request Generation**

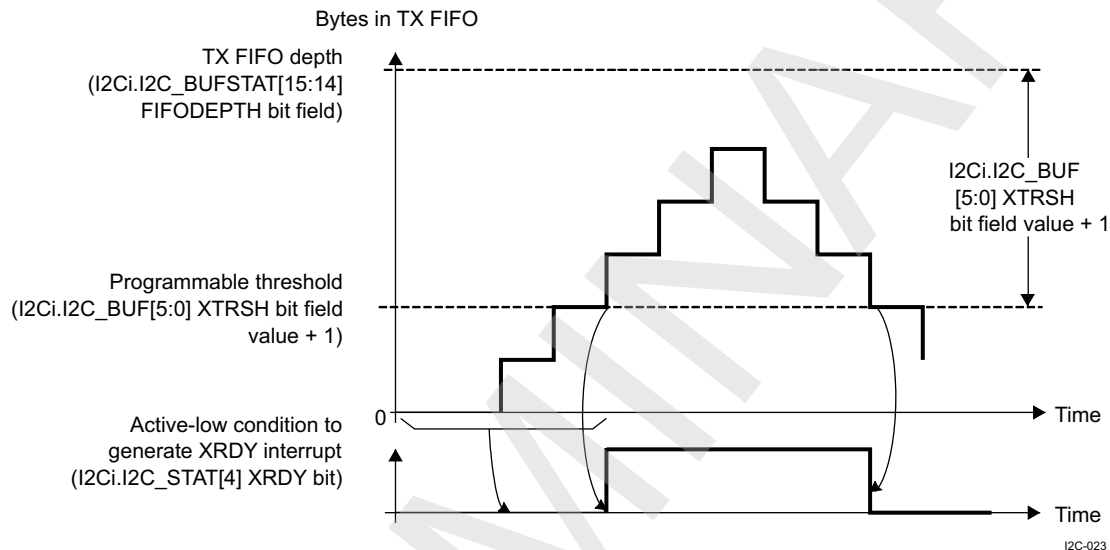

I2C-022

In [Figure 23-23](#), the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the I2Ci.I2C\_STAT[3] RRDY bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2Ci.I2C\_BUF[13:8] RTRSH bit field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

**Figure 23-24. HS I<sup>2</sup>C Transmit FIFO Interrupt Request Generation**

In [Figure 23-24](#), the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by setting the I2Ci.I2C\_STAT[4] XRDY bit to 1 after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is not met.
- When detecting an interrupt request (XRDY or RRDY type), the LH can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C\_BUF[5:0] TXTRSH + 1 or I2C\_BUF[5:0] RXTRSH + 1). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY or RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see [Section 23.1.4.8.4, Draining Feature \[I<sup>2</sup>C Mode Only\]](#)).

**NOTE:** In slave transmit mode (the I2Ci.I2C\_CON[10] MST bit is cleared and the I2Ci.I2C\_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external master can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in slave transmit mode, data can remain in the TX FIFO without being transmitted over the I<sup>2</sup>C bus. In this case, the TX FIFO must be cleared by setting the I2Ci.I2C\_BUF[6] TXFIFO\_CLR bit.

**NOTE:** In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C\_BUF[13:8]RTRSH and I2Ci.I2C\_BUF[5:0] TXTRSH fields to 0x0.

### 23.1.4.8.2 HS I<sup>2</sup>C FIFO Polling Mode

In FIFO polling mode (the I2Ci.I2C\_IE[4] XRDY\_IE and I2Ci.I2C\_IE[3] RRDY\_IE bits are disabled, and the I2Ci.I2C\_BUF[15] RDMA\_EN and I2Ci.I2C\_BUF[7] XDMA\_EN bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2Ci.I2C\_STAT[4] XRDY and the I2Ci.I2C\_STAT[3] RRDY bits (the I2Ci.I2C\_STAT[13] RDR and I2Ci.I2C\_STAT[14] XDR bits can also be polled if the draining feature is enabled). The I2Ci.I2C\_STAT[4] XRDY and I2Ci.I2C\_STAT[3] RRDY bits accurately reflect the interrupt conditions described in the discussion of FIFO interrupt mode.

### 23.1.4.8.3 HS I<sup>2</sup>C FIFO DMA Mode (I<sup>2</sup>C Mode Only)

In receive mode, a DMA request is generated by the I2Ci\_DMA\_RX signal as soon as the RX FIFO exceeds its threshold level (the I2Ci.I2C\_BUF[13:8] RTRSH bit field value + 1). This request is deasserted when the number of bytes defined by the threshold level is read by the DMA controller.

Figure 23-25 shows the DMA request generation in receive mode.

**Figure 23-25. HS I<sup>2</sup>C Receive FIFO DMA Request Generation**

In transmit mode, a DMA request is automatically asserted by the I2Ci\_DMA\_TX signal when the TX FIFO is empty. This request is deasserted when the number of bytes (the I2Ci.I2C\_BUF[5:0] TXTRSH bit field value + 1) is written in the FIFO by the DMA controller. If an insufficient number of bytes is written, the sDMA request remains active. Figure 23-26 and Figure 23-27 show the DMA TX transfers with different values for the I2Ci.I2C\_BUF[5:0] TXTRSH bit field.

**Figure 23-26. HS I<sup>2</sup>C Transmit FIFO Request Generation (High Threshold)****Figure 23-27. HS I<sup>2</sup>C Transmit FIFO Request Generation (Low Threshold)**

**NOTE:** In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C\_BUF[13:8]RTRSH and I2Ci.I2C\_BUF[5:0]XTRSH bit fields to 0x0.

#### 23.1.4.8.4 HS I<sup>2</sup>C Draining Feature (I<sup>2</sup>C Mode Only)

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (the I2Ci.I2C\_BUF[13:8] RTRSH bit field value + 1 for the RX threshold and I2Ci.I2C\_BUF[5:0] TXTRSH field value + 1 for the TX threshold). It can also transfer the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the DMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2Ci.I2C\_STAT[7] AERR bit.

The draining mechanism generates an interrupt using the I2Ci.I2C\_STAT[13] RDR or I2Ci.I2C\_STAT[14] XDR bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2Ci.I2C\_BUFSTAT[13:8] RXSTAT or I2Ci.I2C\_BUFSTAT[5:0] TXSTAT bit fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (master or slave), if the RX FIFO threshold (the I2Ci.I2C\_BUF[13:8] RTRSH bit field value + 1) is not reached, but the transfer ends on the I<sup>2</sup>C bus and data remains in the RX FIFO (less than the threshold), the receive draining interrupt (the I2Ci.I2C\_STAT[13] RDR bit) is asserted to inform the LH that it can read the amount of data in the RX FIFO (the I2Ci.I2C\_BUFSTAT[13:8] RXSTAT bit field). The LH performs a number of data read accesses equal to the I2Ci.I2C\_BUFSTAT[13:8] RXSTAT bit field (interrupt or polling mode), or reconfigures the sDMA controller with the required value to drain the FIFO.

In master transmit mode, if the TX FIFO threshold (I2Ci.I2C\_BUF[5:0] TXTRSH bit field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2Ci.I2C\_STAT[14] XDR bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2Ci.I2C\_BUFSTAT[5:0] TXSTAT bit field). The LH must write the required number of data bytes specified by the I2Ci.I2C\_BUFSTAT[5:0] TXSTAT bit field value or reconfigure the sDMA controller with the value required to transfer the last bytes to the FIFO.

In master mode, the LH can alternately not check the values of the I2Ci.I2C\_BUFSTAT[5:0] TXSTAT and I2Ci.I2C\_BUFSTAT[13:8] RXSTAT bit fields, the LH can obtain this information internally (by computing the I2Ci.I2C\_CNT[15:0] DATACOUNT bit field value modulo I2Ci.I2C\_BUF[13:8] RTRSH or I2Ci.I2C\_BUF[5:0] TXTRSH).

By default, the draining feature is disabled; it can be enabled using the I2Ci.I2C\_IE[14] XDR\_IE or I2Ci.I2C\_IE[13] RDR\_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2Ci.I2C\_BUF[5:0] TXTRSH bit field value + 1 for the TX threshold or I2Ci.I2C\_BUF[13:8] RTRSH bit field value + 1 for the RX threshold).

#### 23.1.4.9 HS I<sup>2</sup>C Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S operation modes and SCCB modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the I2Ci\_INTERNAL\_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For SCCB modes (for example, I2Ci.I2C\_PSC[7:0] PSC bit field = 4), the maximum width of suppressed spikes is 52 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the 2Ci.I2C\_PSC[7:0] PSC bit field.

#### 23.1.4.10 HS I<sup>2</sup>C Write and Read Operations in SCCB Mode

In SCCB mode, the multimaster HS I<sup>2</sup>C controller can write or read a single byte to or from the external SCCB device.

To write a single byte to the external SCCB device, the multimaster HS I<sup>2</sup>C controller must be configured in multimaster transmitter mode by setting the I2Ci.I2C\_CON[10] MST and I2Ci.I2C\_CON[9] TRX bits to 1. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C\_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C\_OA0 register. The 8-bit data to be transmitted is written by the LH in the I2Ci.I2C\_DATA register.

To read a single byte from the external SCCB device, the multimaster HS I<sup>2</sup>C controller must be configured in multimaster receiver mode by setting the I2Ci.I2C\_CON[10] MST bit to 1 and by clearing the I2Ci.I2C\_CON[9] TRX bit to 0. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C\_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C\_OA0 register. The 8-bit data received from the external SCCB device is read by the LH from the I2Ci.I2C\_DATA register.

**NOTE:** In SCCB mode, the RX and TX thresholds must be set to 1 by configuring the I2Ci.I2C\_BUF[13:8] RTRSH and I2Ci.I2C\_BUF[5:0]XTRSH fields to 0x0.

### 23.1.4.11 HS I<sup>2</sup>C System Test Mode

A system test mode is available for multimaster HS I<sup>2</sup>C controller module testing. This mode is enabled by setting the I2Ci.I2C\_SYSTEST[15] ST\_EN bit to 1. When this bit is cleared to 0, the I<sup>2</sup>C controller is configured in normal operation mode.

In system test mode, the I2Ci\_SYSTEST[13:12] TMODE bit field selects the type of test. Table 23-14 lists the tests available for the multimaster HS I<sup>2</sup>C controllers.

**Table 23-14. HS I<sup>2</sup>C List of Tests**

I2Ci.I2C_SYSTEST[13:12] TMODE	Test	Description
00	Functional mode	Normal operation mode
01	Reserved (not used)	
10	Test of i2ci_scl serial clock line	The i2ci_scl line is driven with a permanent clock as if mastered with the parameters set in the I2Ci.I2C_PSC, I2Ci.I2C_SCLL, and I2Ci.I2C_SCLH registers.
11	Loop-back mode + i2ci_scl/ i2ci_sda input/output	In master transmit mode only, data transmitted out of the I2Ci.I2C_DATA register (write action) is received in the same I2Ci.I2C_DATA register through an internal path through the FIFO buffers. The DMA and interrupt requests are normally generated if they are enabled. Moreover, the i2ci_scl, i2ci_sda, and i2ci_sccbe lines are controlled with the I2Ci.I2C_SYSTEST[4:0] bits..

**NOTE:** When the I2Ci.I2C\_SYSTEST[13:12] TMODE bit field is set to 11, the I<sup>2</sup>C controller must be configured in I<sup>2</sup>C F/S (the I2Ci.I2C\_CON[13:12] OPMODE set to 00) or I<sup>2</sup>C HS mode (the I2Ci.I2C\_CON[13:12] OPMODE set to 01). The loop-back mode is not available in SCCB mode (the I2Ci.I2C\_CON[13:12] OPMODE = b10).

**NOTE:** In normal operation mode (I2Ci.I2C\_SYSTEST[15] ST\_EN clear to 0), the I2Ci.I2C\_SYSTEST[4:0] bits that control the i2ci\_scl, i2ci\_sda, and i2ci\_sccbe lines in system test mode are read-only bits.

In system test mode (I2Ci.I2C\_SYSTEST[15] ST\_EN set to 1), the I2Ci.I2C\_STAT[5:0] status bits can be set to 1 when the I2Ci.I2C\_SYSTEST[11] SSB bit is set to 1. Clearing the I2Ci.I2C\_SYSTEST[11] SSB bit to 0 does not clear the I2Ci.I2C\_STAT[5:0] bits to 0. The I2Ci.I2C\_STAT[5:0] bit field can be cleared to 0 only by writing 1 in the corresponding bits.

## 23.1.5 HS I<sup>2</sup>C Programming Guide

### 23.1.5.1 HS I<sup>2</sup>C Low-Level Programming Models

#### 23.1.5.1.1 HS I<sup>2</sup>C Programming Model in I<sup>2</sup>C Mode

This section describes the programming model of the multimaster HS I<sup>2</sup>C controllers configured in I<sup>2</sup>C mode.

##### 23.1.5.1.1.1 Main Program

###### 23.1.5.1.1.1.1 Configure the Module Before Enabling the I<sup>2</sup>C Controller

Before enabling the I<sup>2</sup>C controller, perform the following:

1. Enable the functional and interface clocks.
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock by programming the corresponding value in the I2Ci.I2C\_PSC[7:0] PSC field. This value depends on the frequency of the functional clock (I2Ci\_FCLK).
3. Program the I2Ci.I2C\_SCLL[7:0] SCLL and I2Ci.I2C\_SCLH[7:0] SCLH bit fields to obtain a bit rate of 100 Kbps, 400 Kbps or 1Mbps. These values depend on the internal sampling clock frequency (see [Table 23-8](#)).
4. (Optional) Program the I2Ci.I2C\_SCLL[15:8] HSSCLL and I2Ci.I2C\_SCLH[15:8] HSSCLH bit fields to obtain a bit rate of 400 Kbps or 3.4 Mbps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see [Table 23-8](#)).
5. (Optional) If a bit rate of 3.4 Mbps is used and the bus line capacitance exceeds 45 pF, see [Section 18.4.8, PAD Functional Multiplexing and Configuration](#).
6. Configure the Own Address of the I2C controller by storing it in the I2Ci.I2C\_OA register. Up to four Own Addresses can be programmed in the I2Ci.I2C\_OAx registers (where x = 0, 1, 2, 3) for each I<sup>2</sup>C controller.

---

**NOTE:** For a 10-bit address, set the corresponding expand Own Address bit in the I2Ci.I2C\_CON register.

---

7. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2Ci.I2C\_BUF[5:0] TXTRSH bit field to (TX threshold to 1) and the I2Ci.I2C\_BUF[13:8] RTRSH bit field to (RX threshold to 1), where the TX and RX thresholds are greater than or equal to 1.
8. Take the I<sup>2</sup>C controller out of reset by setting the I2Ci.I2C\_CON[15] I2C\_EN bit to 1.

###### 23.1.5.1.1.1.2 Initialize the I<sup>2</sup>C Controller

To initialize the I<sup>2</sup>C controller, perform the following steps:

1. Configure the I2Ci.I2C\_CON register:
  - For master or slave mode, set the I2Ci.I2C\_CON[10] MST bit (0: slave; 1: master).
  - For transmitter or receiver mode, set the I2Ci.I2C\_CON[9] TRX bit (0: receiver; 1: transmitter).
2. If using an interrupt to transmit and receive data, set the corresponding bit in the I2Ci.I2C\_IE register to 1 (the I2Ci.I2C\_IE[4] XRDY\_IE bit for the transmit interrupt, the I2Ci.I2C\_IE[3] RRDY bit for the receive interrupt).
3. If using DMA to receive and transmit data, set the corresponding bit in the I2Ci.I2C\_BUF register to 1 (the I2Ci.I2C\_BUF[15] RDMA\_EN bit for the receive DMA channel, the I2Ci.I2C\_BUF[7] XDMA\_EN bit for the transmit DMA channel).

### 23.1.5.1.1.1.3 Configure Slave Address and the Data Control Register

In master mode, configure the slave address register by programming the I2Ci.I2C\_SA[9:0] SA bit field and the number of data bytes (I<sup>2</sup>C data payload) associated with the transfer by programming the I2Ci.I2C\_CNT[15:0] DCOUNT bit field.

---

**NOTE:** For a 10-bit address, set the I2Ci.I2C\_CON[8] XSA bit to 1.

---

### 23.1.5.1.1.1.4 Initiate a Transfer

Poll the I2Ci.I2C\_STAT[12] BB bit. If it is cleared to 0 (bus not busy), configure the I2Ci.I2C\_CON[0] STT and I2Ci.I2C\_CON[1] STP bits. To initiate a transfer, the I2Ci.I2C\_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2Ci.I2C\_CON[1] STP bit to 1.

### 23.1.5.1.1.1.5 Receive Data

Poll the I2Ci.I2C\_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C\_IE[3] RRDY\_IE bit must be set to 1) or the DMA RX channel (the I2Ci.I2C\_BUF[15] RDMA\_EN bit must be set to 1) to read the receive data in the I2Ci.I2C\_DATA register.

If the transfer length does not equal the RX FIFO threshold (I2Ci.I2C\_BUF[13:8] RTRSH field + 1), use the draining feature (enable the RDR interrupt by setting the I2Ci.I2C\_IE[13] RDR\_IE bit to 1).

---

**NOTE:** In receive mode only, the I2Ci.I2C\_STAT[11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I<sup>2</sup>C controller simply holds i2ci\_scl to low to prevent other bytes from being received.

The I2Ci.I2C\_STAT[7] AERR bit is set to 1 when a read access is performed in the I2Ci.I2C\_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2Ci.I2C\_IE[7] AERR\_IE bit to 1.

---

### 23.1.5.1.1.1.6 Transmit Data

Poll the I2Ci.I2C\_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C\_IE[4] XRDY\_IE bit must be set to 1) or the DMA TX channel (the I2Ci.I2C\_BUF[7] XDMA\_EN bit must be set to 1) to write data to the I2Ci.I2C\_DATA register.

If the transfer length does not equal the TX FIFO threshold (I2Ci.I2C\_BUF[5:0] TXTRSH field + 1), use the draining feature (enable the XDR interrupt by setting the I2Ci.I2C\_IE[14] XDR\_IE bit to 1).

---

**NOTE:** In transmit mode only, the I2Ci.I2C\_STAT[10] XUDF bit indicates whether the transmitter has experienced underflow.

In master transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the value of the I2Ci.I2C\_CNT[15:0] DCOUNT bit field is not 0).

In slave transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I<sup>2</sup>C master device still requests data bytes to be read.

The I2Ci.I2C\_STAT[7] AERR bit is set to 1 when a write access is performed in the I2Ci.I2C\_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2Ci.I2C\_IE[7] AERR\_IE bit to 1.

---

### 23.1.5.1.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (the I2Ci.I2C\_STAT[0] AL bit) and resolve accordingly.
2. Test for no acknowledgment (the I2Ci.I2C\_STAT[1] NACK bit) and resolve accordingly.
3. Test for register access ready (the I2Ci.I2C\_STAT[2] ARDY bit) and resolve accordingly.

4. Test for receive data ready (the I2Ci.I2C\_STAT[3] RRDY bit) and resolve accordingly.
5. Test for transmit data ready (the I2Ci.I2C\_STAT[4] XRDY bit) and resolve accordingly.
6. Test for general call (the I2Ci.I2C\_STAT[5] GC bit) and resolve accordingly.
7. Test for start (S) condition (the I2Ci.I2C\_STAT[6] STC bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (the I2Ci.I2C\_STAT[7] AERR bit) and resolve accordingly.
9. Test for bus free (the I2Ci.I2C\_STAT[8] BF bit) and resolve accordingly.

#### **23.1.5.1.1.3 Programming Flow Diagrams**

Figure 23-28 through Figure 23-36 are procedure flow charts for programming the F/S and HS I<sup>2</sup>C modes.

### 23.1.5.1.2 HS I<sup>2</sup>C (I2C5) Programming Model for Communication With Power Chips

This section describes the programming model of the master transmitter HS I<sup>2</sup>C controller (I2C5) for communication with one or more power chips. The HS I<sup>2</sup>C controller (I2C5) allows the two voltage Finite State Machines (FSMs) in the PRCM module of the device to be interfaced to external power chips through the I<sup>2</sup>C bus for dynamic voltage control of two power supplies and power sequencing. The primary programming tasks are to set up the configuration registers according to the external power supply chip(s) being used.

#### 23.1.5.1.2.1 Configure the Voltage Controller Registers

To use the voltage control function, the LH must configure the following registers in the voltage controller of the APE and 3G modem SS PRCM modules:

- The voltage configuration register address for each VDD channel in the PRCM.PRM\_VC\_VAL\_SMPS\_RA\_VOL register
- The ON/ON-low-power-Retention/OFF command configuration register address for each VDD channel in the PRCM.PRM\_VC\_VAL\_SMPS\_RA\_CMD register
- The set of ON/ON-low-power/Retention/OFF voltage/mode values in the APE PRCM.PRM\_VC\_VAL\_CMD\_VDD\_CORE\_L, APE PRCM.PRM\_VC\_VAL\_CMD\_VDD\_IVA\_L, and APE PRCM.PRM\_VC\_VAL\_CMD\_VDD\_MPU\_L registers, and 3G modem SS PRCM.PRM\_VC\_VAL\_CMD\_VDD\_WGM\_L register.
- The VDD channels configuration selection in the PRCM.PRM\_VC\_CFG\_CHANNEL register

For more information about the voltage controller register configuration, see [Chapter 3, Power, Reset, and Clock Management](#).

### 23.1.5.1.2.2 Configure the HS I<sup>2</sup>C Controller I2C5

At power-on reset (POR), the I2C5 is in HS mode (PRCM.PRM\_VC\_CFG\_I2C\_MODE[3] HSMODEEN bit). In HS mode, the LH must configure the master code value for the preamble I<sup>2</sup>C high-speed transmission by configuring the PRCM.PRM\_VC\_CFG\_I2C\_MODE[2:0] HSMCODE bit field. If the external power chips do not support the I<sup>2</sup>C HS mode, HS mode can be disabled and F/S mode enabled by clearing the PRCM.PRM\_VC\_CFG\_I2C\_MODE[3] HSMODEEN bit to 0.

By default, the Sr operation is enabled (PRCM.PRM\_VC\_CFG\_I2C\_MODE[4] SRMODEEN bit set to 1 at POR). In F/S mode, the Sr operation can be disabled by clearing the PRCM.PRM\_VC\_CFG\_I2C\_MODE[4] SRMODEEN bit to 0.

### 23.1.5.1.3 HS I<sup>2</sup>C Basic Programming Model in SCCB Mode

This section describes the programming model of the multimaster HS I<sup>2</sup>C controllers configured in SCCB mode.

#### 23.1.5.1.3.1 Main Program

##### 23.1.5.1.3.1.1 Configure the Module Before Enabling the I<sup>2</sup>C Controller

Before enabling the I<sup>2</sup>C controller, perform the following steps:

1. Enable the functional and interface clocks (see [Table 23-7](#)).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock (I2Ci\_INTERNAL\_CLK) by programming the corresponding value in the I2Ci.I2C\_PSC[7:0] PSC field. This value depends on the frequency of the functional clock (I2Ci\_FCLK). Because this frequency is 96MHz, the I2Ci.I2C\_PSC[7:0] PSC field value is 0x7.
3. Program the I2Ci.I2C\_SCLL[7:0] SCLL and I2Ci.I2C\_SCLH[7:0] SCLH fields to obtain a bit rate of 100K bps (maximum authorized bit rate in SCCB mode). This value depends on the internal sampling clock frequency (see [Table 23-8](#)).
4. Configure the 7-bit slave address (ID value) by storing it in the I2Ci.I2C\_SA register.
5. Configure the 8-bit register address (subaddress) by storing it in the I2Ci.I2C\_OA0 register.
6. Configure the I2Ci.I2C\_BUF[13:8]RTRSH field to 0x0 (RX threshold to 1) and the I2Ci.I2C\_BUF[5:0]XTRSH field to 0x0 (TX threshold to 1).
7. Take the I<sup>2</sup>C controller out of reset by setting the I2Ci.I2C\_CON[15] I2C\_EN bit to 1.

##### 23.1.5.1.3.1.2 Initialize the I<sup>2</sup>C Controller

To initialize the I<sup>2</sup>C controller, perform the following steps:

1. Configure the I2Ci.I2C\_CON register:
  - In SCCB mode, only the master mode is supported; set the I2Ci.I2C\_CON[10] MST bit to 1.
  - For transmitter mode (write to the external SCCB device register) or receiver mode (read from the external SCCB device register), set the I2Ci.I2C\_CON[9] TRX bit (0: receiver, 1: transmitter).
2. If using an interrupt to transmit/receive data, set to 1 the corresponding bit in the I2Ci.I2C\_IE register (the I2Ci.I2C\_IE[4] XRDY\_IE bit for the transmit interrupt, the I2Ci.I2C\_IE[3] RRDY bit for the receive

interrupt).

#### 23.1.5.1.3.1.3 Initiate a Transfer

Poll the I2Ci.I2C\_STAT[12] BB bit. If it is cleared to 0 (bus not busy), set the I2Ci.I2C\_CON[0] STT bit to 1. Because a transfer allows the LH to write or read only a single byte to or from the external SCCB device, the transmission automatically stops at the end of the transfer. When the transfer is complete, the I2Ci.I2C\_STAT[2] ARDY bit is set to 1. In SCCB mode, the I2Ci.I2C\_CON[1] STP bit is not used.

#### 23.1.5.1.3.1.4 Receive Data

Poll the I2Ci.I2C\_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C\_IE[3] RRDY\_IE bit must be set to 1) to read the receive data in the I2Ci.I2C\_DATA register.

---

**NOTE:** In SCCB mode, the I2Ci.I2C\_BUF[13:8] RTRSH field (RX threshold) must be set to a value of 0x0 (RX threshold = 1).

---

#### 23.1.5.1.3.1.5 Transmit Data

Poll the I2Ci.I2C\_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C\_IE[4] XRDY\_IE bit must be set to 1) to write the data to the I2Ci.I2C\_DATA register.

---

**NOTE:** In SCCB mode, the I2Ci.I2C\_BUF[5:0] TXTRSH field (TX threshold) must be set to a value of 0x0 (TX threshold = 1).

---

#### 23.1.5.1.3.2 Interrupt Subroutine Sequence

1. Test for register access ready (I2Ci.I2C\_STAT[2] ARDY status bit) and resolve accordingly.
2. Test for receive data ready (I2Ci.I2C\_STAT[3] RRDY status bit) and resolve accordingly.
3. Test for transmit data ready (I2Ci.I2C\_STAT[4] XRDY status bit) and resolve accordingly.

#### 23.1.5.1.3.3 Programming Flow Diagrams

Figure 23-37 through Figure 23-41 are procedure flowcharts for programming the SCCB mode.

**Table 23-39. I2C\_IRQSTATUS\_RAW**

<b>Address Offset</b>	0x0000 0024
<b>Physical Address</b>	See <a href="#">Table 23-31</a>
<b>Description</b>	Per-event raw interrupt status vector
<b>Type</b>	RW

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED		XDR	RDR	BB	ROVR	XUDF	AAS	BF	AERR	STC	GC	XRDY	RRDY	ARDY	NACK	AL

Bits	Field Name	Description	Type	Reset
15	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
14	XDR	Transmit draining IRQ status. 0x0: Transmit draining inactive. 0x1: Transmit draining enabled.	RW	0
13	RDR	Receive draining IRQ status. 0x0: Receive draining inactive. 0x1: Receive draining enabled.	RW	0
12	BB	Bus busy status. Writing into this bit has no effect. Read 0x1: Bus is occupied. Read 0x0: Bus is free.	R	0
11	ROVR	Receive overrun status. Writing into this bit has no effect. Read 0x1: Receiver overrun. Read 0x0: Normal operation.	RW	0
10	XUDF	Transmit underflow status. Writing into this bit has no effect. Read 0x1: Transmit underflow. Read 0x0: Normal operation.	RW	0
9	AAS	Address recognized as slave IRQ status. 0x0: No action. 0x1: Address recognized.	RW	0
8	BF	Bus Free IRQ status. 0x0: No action. 0x1: Bus Free.	RW	0
7	AERR	Access Error IRQ status. 0x0: No action. 0x1: Access Error.	RW	0
6	STC	Start Condition IRQ status. 0x0: No action. 0x1: Start Condition detected.	RW	0
5	GC	General call IRQ status. Set to '1' by core when General call address detected and interrupt signaled to MPUSS. Write '1' to clear. 0x0: No general call detected. 0x1: General call address detected.	RW	0

Bits	Field Name	Description	Type	Reset
4	XRDY	Transmit data ready IRQ status. Set to '1' by core when transmitter and when new data is requested. When set to '1' by core, an interrupt is signaled to MPUSS. Write '1' to clear. 0x0: Transmission ongoing. 0x1: Transmit data ready.	RW	0
3	RRDY	Receive data ready IRQ status. Set to '1' by core when receiver mode, a new data is able to be read. When set to '1' by core, an interrupt is signaled to MPUSS. Write '1' to clear. 0x0: No data available. 0x1: Receive data available.	RW	0
2	ARDY	Register access ready IRQ status. When set to '1' it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPUSS. Write '1' to clear. 0x0: Module busy. 0x1: Access ready.	RW	0
1	NACK	No acknowledgement IRQ status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPUSS. Write '1' to clear this bit. 0x0: Normal operation. 0x1: Not Acknowledge detected.	RW	0
0	AL	Arbitration lost IRQ status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to MPUSS. During reads, it always returns 0. 0x0: Normal operation. 0x1: Arbitration lost detected.	RW	0

## 23.2 HDQ/1-Wire

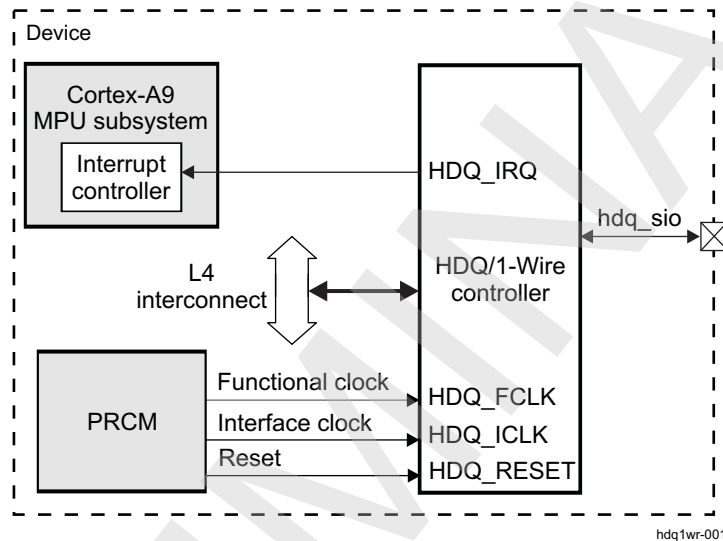

This section describes the HDQ/1-Wire interface for the device.

### 23.2.1 HDQ/1-Wire Overview

The HDQ/1-Wire module implements the hardware protocol of the master functions of the TI/Benchmark HDQ and the Dallas Semiconductor 1-Wire® protocols. These protocols use a single wire for communication between the master (HDQ/1-Wire controller) and the slaves (HDQ/1-Wire external compliant devices).

Figure 23-42 shows the HDQ/1-Wire.

Figure 23-42. HDQ/1-Wire Overview

The HDQ/1-Wire has a generic L4 interface and is intended to be used in an interrupt-driven fashion. The one-pin interface is implemented as an open-drain output at the device level.

The main features supported by the HDQ/1-Wire are the following:

- Benchmark HDQ protocol
- Dallas Semiconductor 1-Wire® protocol
- Power-down mode

The HDQ/1-Wire provides a communication rate of 5 Kbps over an address space of 128 bytes.

A typical application of the HDQ/1-Wire is the communication with battery monitor (gas gauge) integrated circuits.

## 23.2.2 HDQ/1-Wire Environment

### 23.2.2.1 HDQ/1-Wire Functional Modes

The HDQ/1-Wire has two main modes: HDQ and 1-Wire. Each of these modes includes idle, active, and power-down submodes. [Table 23-99](#) lists the HDQ/1-Wire functional modes, and [Figure 23-43](#) shows an overview of a typical application.

**Table 23-99. Functional Modes**

Functions	Description
HDQ	Benchmark HDQ protocol
1-Wire	Dallas Semiconductor 1-Wire protocol

**Figure 23-43. HDQ/1-Wire Typical Application System Overview**

An external pullup is required, because the two protocols use a return-to-1 mechanism (that is, after any command by any of the connected devices, the line is pulled to a logical high level).

The HDQ/1-Wire operates according to a command structure that is programmed into transmit command registers (as described in [Section 23.2.5.1.2, HDQ/1-Wire Low-level Programming Model](#)).

The 1-Wire mode runs at slower speeds than the capabilities of the mode.

[Table 23-100](#) describes the external signal of the HDQ/1-Wire compliant module.

**Table 23-100. I/O Description**

Signal	I/O <sup>(1)</sup>	Description	Value at Reset
hdq_sio	I/O	Serial data input/output. Output is open drain type.	HiZ (pulled to 1 by pullup)

<sup>(1)</sup> I = Input; O = Output

### 23.2.2.2 HDQ and 1-Wire (SDQ) Protocols

#### 23.2.2.2.1 HDQ Protocol Initialization (Default)

In HDQ mode, the firmware does not require the host to create an initialization pulse to the slave. However, the slave can be reset by using an initialization pulse (also referred to as a break pulse). The initialization pulse is generated by setting the [HDQ\\_CTRL\\_STATUS\[2\]](#) INITIALIZATION bit and then setting the [HDQ\\_CTRL\\_STATUS\[4\]](#) GO bit. The slave does not respond with a presence pulse as it does in the 1-Wire protocol.

The HDQ is a command-based protocol in which the host sends a command byte to the slave. The command directs the slave either to store the next eight bits of data received to a register specified by the command byte (write operation) or to output the eight bits of data from a register specified by the command byte (read operation). The master implementation is a simple byte engine. Sending of the ID, command/address, and data is controlled by firmware. The master engine provides only a single HDQ.[HDQ\\_TX\\_DATA](#) register.

The command and data bytes consist of a stream of eight bits with a maximum transmission rate of 5 Kbps. The least-significant bit (LSB) of a command or data byte is transmitted first. If a communication time-out occurs between the host and the slave (for example, if the host waits longer than the specified time for the slave to respond, or if this is the first access command), then the host must send an initialization pulse (BREAK) before sending the command again.

The slave detects a break when the HDQ pin is driven to a logic-low state for a specified break time  $t_{(B)}$  or greater. The HDQ pin then returns to its normal ready-high logic state for a specified break-recovery time  $t_{(BR)}$ . The slave is then ready for a command from the host processor. Figure 23-44 shows this behavior.

An interrupt condition indicates a TX-complete, an RX-complete, or a time-out condition. Reading the interrupt status register clears all interrupt conditions. Only one interrupt signal is sent to the microcontroller, and only one overall mask bit can enable or disable the interrupt. The interrupt conditions cannot be individually masked.

Figure 23-44. HDQ Break-Pulse Timing Diagram

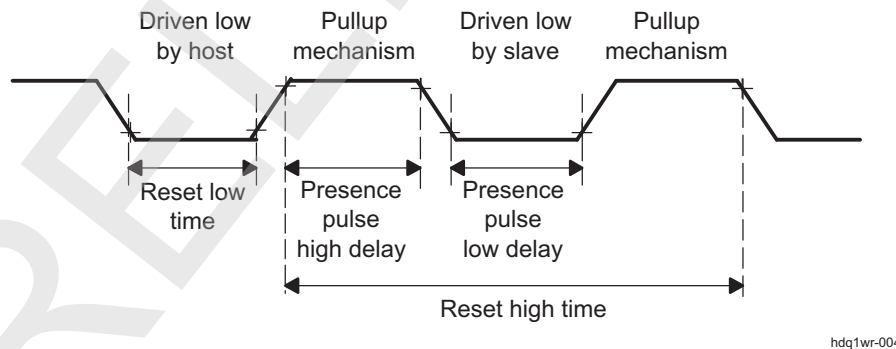

23.2.2.2.2 1-Wire (SDQ) Protocol Initialization

In 1-Wire (SDQ) protocol, the host first sends an initialization pulse (by pulling the line to a logic-low state) and then waits for the slave to respond with a presence pulse before enabling any communication sequence.

As for the initialization pulse, the presence pulse is a low-going edge on the line initiated by the slave. The timing diagram in Figure 23-45 shows the 1-Wire (SDQ) reset sequence.

Figure 23-45. 1-Wire (SDQ) Reset Timing Diagram

The host drives the line to a logic-low state for a minimum of reset low time. Once the slave detects this pulse, it must drive the line to a logic-low state within the presence pulse high delay for a minimum period of presence pulse low time.

If the slave does not respond within this interval of time, a time-out event occurs and no transaction can be initiated. The host must initiate the reset sequence again before sending any command to the slave.

On the other hand, if the slave sends back its presence pulse within the specified time interval, the communication can be enabled after the reset high time.

23.2.2.2.3 Communication Sequence (HDQ and 1-Wire Protocols)

The description in this section applies to both protocols.

After a successful break pulse (HDQ mode) or initialization sequence (1-Wire protocol), the host and slave are ready for bit transmission. Each bit to transmit (either from the host to the slave or from the slave to the host) is preceded by a low-going edge on the line, as shown in [Figure 23-46](#).

**Figure 23-46. HDQ/1-Wire Transmitted Bit Timing**

hdq1wr-005

The return-to-1 data-bit frame consists of three distinct sections. The first section starts the transmission when either the slave or the host takes the line to a logic-low state. The next section is the actual data transmission in which the data must be valid during a specified period of time after the negative edge that starts the communication. The final section stops the transmission by returning the HDQ/1-Wire line to a logic-high state. Communication with an HDQ/1-Wire slave always occurs with the LSB being transmitted first.

The command byte of the HDQ/1-Wire protocols consists of eight contiguous valid command bits. The command byte contains two fields: R/W command and address. The R/W bit of the command byte determines whether the command is a read or a write, and the address field containing bits AD6-AD0 indicates the address to be read or written. [Table 23-101](#) lists the command byte values.

**Table 23-101. HDQ/1-Wire Command Byte**

7	6	5	4	3	2	1	0
R/W	AD6	AD5	AD4	AD3	AD2	AD1	AD0

**R/W** Indicates whether the command byte is a read or a write. A 1 indicates a write command; the following eight bits must be written to the register specified by the address field of the command byte. A 0 indicates that the command is a read. On a read command, the slave outputs the requested register contents.

**AD6-AD0** Represent the seven bits labeled AD6-AD0 containing the address portion of the register to be accessed.

The communication sequence example in [Figure 23-47](#) shows a read command at address 0x55; the received data is 0x65.

**Figure 23-47. HDQ/1-Wire Communication Sequence**

hdq1wr-006

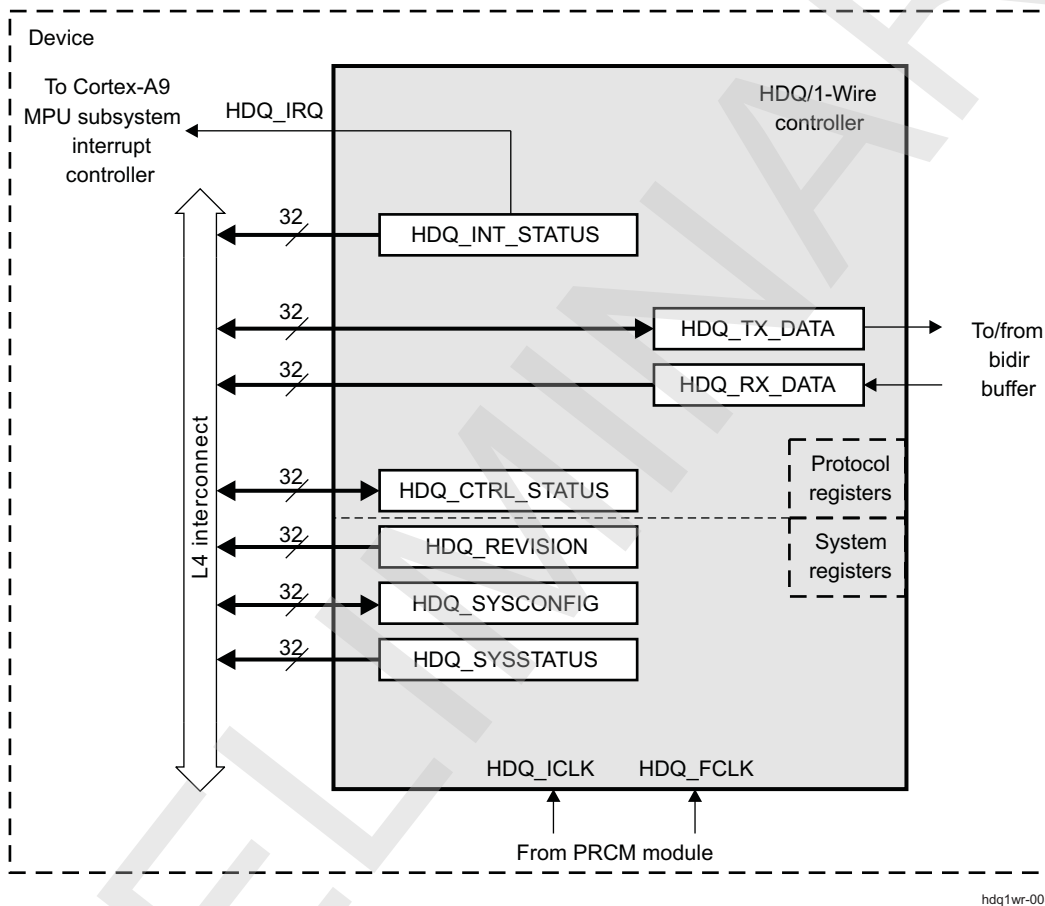

### 23.2.3 HDQ/1-Wire Functional Description

The HDQ/1-Wire works with HDQ and 1-Wire protocols. The protocols use a single wire to establish communication between the master and the slave. Both protocols use a return-to-1 mechanism; that is, after any command is driven, the line is pulled to a high level. This mechanism requires an external pullup.

#### 23.2.3.1 HDQ/1-Wire Block Diagram

Figure 23-48 is the HDQ/1-Wire block diagram.

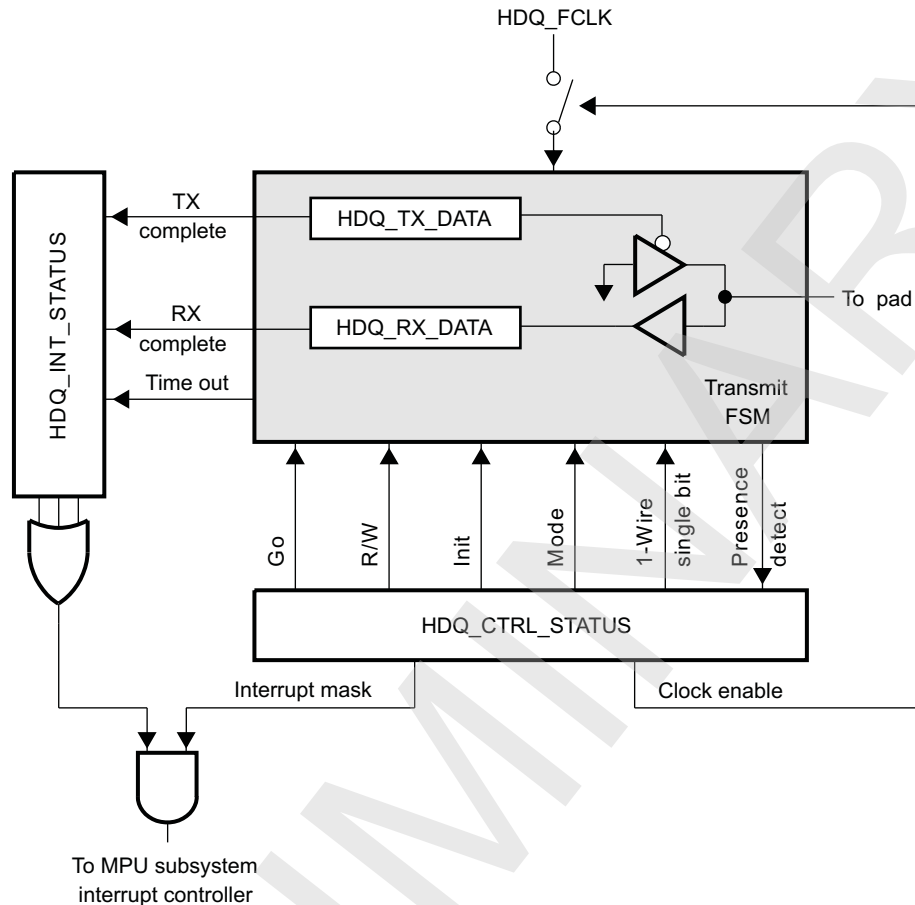

Figure 23-48. HDQ/1-Wire Block Diagram

The HDQ.HDQ\_CTRL\_STATUS[0] MODE bit allows selection between the HDQ and 1-Wire protocols. This bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Figure 23-49 shows the protocol-dedicated register scheme.

Figure 23-49. Protocol Registers Description

hdq1wr-009

The receive and transmit operations of the HDQ/1-Wire module are performed with respect to the timing of the slower HDQ protocol. When the 1-Wire protocol is used, it runs at lower speed than its full capabilities, but is still able to meet the timing requirements and practical considerations.

### 23.2.3.2 HDQ/1-Wire Clocking Configuration

#### 23.2.3.2.1 HDQ/1-Wire Clocks

The HDQ/1-Wire subsystem operates from two clocks: a functional clock (HDQ\_FCLK) and an interface clock (HDQ\_ICLK).

- The HDQ\_FCLK functional clock is a fixed clock provided by the PRCM module. It is used to clock the internal module logic.

For more information about the clock, see [Section 3.6.8, CD\\_L4\\_PER Clock Domain](#).

When the HDQ/1-Wire no longer requires the HDQ\_FCLK, the software can disable it at the PRCM level. The clock is effectively cut, provided the other modules that receive it do not require it either.

For details about the PRCM register settings and clock configuration, see [Section 3.6.8, CD\\_L4\\_PER Clock Domain](#).

- The HDQ\_ICLK interface clock runs at L4 interconnect clock speed and is used to trigger access to the HDQ/1-Wire L4 interface.

When the HDQ/1-Wire no longer requires the HDQ\_ICLK (no transfer is in progress), the software can disable it at the PRCM level. The clock is effectively cut, provided the other modules that receive it do not require it either.

For more information, see [Section 3.6.8, CD\\_L4\\_PER Clock Domain](#).

### 23.2.3.3 HDQ/1-Wire Hardware and Software Reset

Global reset of the module is done at the power, reset, and clock management (PRCM) module level (for more information, see [Section 3.6.8, CD\\_L4\\_PER Clock Domain](#)) or by setting the HDQ.HDQ\_SYSCONFIG[1] SOFTRESET bit to 1. Setting this bit enables an active software reset functionality equivalent to a hardware reset. The HDQ\_FCLK functional clock must be enabled from the PRCM level and locally through the HDQ\_CTRL\_STATUS[5] CLOCKENABLE bit (set to 1) for the software reset to complete.

### 23.2.3.4 HDQ/1-Wire Power Management

[Table 23-102](#) describes power-management features available to the HDQ/1-Wire.

**Table 23-102. Local Power-Management Features**

Feature	Registers	Description
Clock auto gating	HDQ_SYSCONFIG [0] AUTOIDLE bit	Auto-idle mode
Slave idle modes	N/A	N/A
Clock enable	HDQ.HDQ_CTRL_STATUS[5] CLOCKENABLE bit	Power-down mode
Master standby modes	N/A	N/A
Global wake-up enable	N/A	N/A
Wake-up sources enable	N/A	N/A

#### 23.2.3.4.1 Auto-Idle Mode

The HDQ/1-Wire provides an auto-idle function in its interconnect clock domain.

The interconnect clock auto-idle power-saving mode is enabled or disabled through the HDQ.HDQ\_SYSCONFIG[0] AUTOIDLE bit. When this mode is enabled and there is no activity on the interconnect interface, the interconnect clock (HDQ\_ICLK) is disabled inside the module, thereby reducing power consumption. When there is new activity on the interconnect interface, the interconnect clock is restarted with no latency penalty. This mode is disabled by default after a reset.

The auto-idle mode can be enabled in order to reduce power consumption.

#### 23.2.3.4.2 Power-Down Mode

The HDQ/1-Wire also provides a power-saving function in its functional clock domain.

Setting the CLOCKENABLE bit in the control and status register (HDQ.HDQ\_CTRL\_STATUS[5] CLOCKENABLE bit) to 0 shuts off the functional clock (HDQ\_FCLK) to the state-machine. The state-machine is reset when the functional clock is disabled; if any transaction is ongoing, it is aborted into the reset state.

Before shutting off the functional clock, the software must wait for transaction-complete interrupt. In write operation the software must check whether the interrupt was generated after address/command byte was sent or after data byte was sent. The functional clock must not be shut off after address/command byte is sent; otherwise, the data is not written to the slave.

The register values are not affected by disabling the functional clock.

#### CAUTION

There is no hardware mechanism to prevent cutting off the HDQ/1-Wire clocks while the module is performing a transfer. This would result in loss of data being transferred.

### 23.2.3.5 HDQ Interrupt Requests

The HDQ/1-Wire module is intended to be used in an interrupt-driven way. If interrupts are masked, the [HDQ\\_CTRL\\_STATUS\[4\] GO](#) bit does not self-clear after the operation completes. Software then must clear the GO bit to avoid continuous execution.

The HDQ/1-Wire can generate one interrupt:

- [HDQ\\_IRQ](#): This is an interrupt to the MPU subsystem INTC. It is mapped on [MA\\_IRQ\\_58](#). [Table 23-103](#) lists the events that can generate this interrupt.

**Table 23-103. Events**

Event Flag	Event Mask	Sync	Sensitivity	Map to	Description
<a href="#">HDQ_INT_STATUS[2] TXCOMPLETE</a>	<a href="#">HDQ_CTRL_STATUS[31] INTERRUPTMASK</a>	Yes	Level	<a href="#">HDQ_IRQ</a>	A write operation of one byte was completed.
<a href="#">HDQ_INT_STATUS[1] RXCOMPLETE</a>	<a href="#">HDQ_CTRL_STATUS[31] INTERRUPTMASK</a>	Yes	Level	<a href="#">HDQ_IRQ</a>	A byte has been successfully read.
<a href="#">HDQ_INT_STATUS[0] TIMEOUT</a>	<a href="#">HDQ_CTRL_STATUS[31] INTERRUPTMASK</a>	Yes	Level	<a href="#">HDQ_IRQ</a>	After a read command initiated by the host, the slave did not pull the line low within the specified time.

### 23.2.3.6 HDQ Mode (Default)

#### 23.2.3.6.1 HDQ Mode Features

The HDQ mode supports the following:

- Benchmark HDQ protocol
- Power-down mode

#### 23.2.3.6.2 Description

In the HDQ mode, there is no need for the host to create an initialization pulse to the slave. However, the host can reset the slave by using an initialization pulse (also known as a break pulse). Setting the [HDQ.HDQ\\_CTRL\\_STATUS\[2\] INITIALIZATION](#) bit and then setting the [HDQ\\_CTRL\\_STATUS\[4\] GO](#) bit creates this pulse by pulling the line down for a defined duration. When the slave receives the pulse, it is ready for communication but does not respond with a presence pulse.

In a typical write operation, two bytes are sent to the slave. The first byte corresponds to the command/address byte, and the second byte corresponds to the data to be written.

In a typical read operation, the host sends a command/address byte and the slave returns a byte of data.

The master is implemented to send and receive bytes. Sending the command/address and data is controlled by the firmware. The master provides only a single data TX register.

The HDQ protocol is a return-to-1 protocol. Consequently, after a byte is sent to the slave (either command/address + data for a write, or just command/address for a read), the host pulls the line up. The line is set to the high-impedance state in the device and an external pullup brings it to a logical high level.

In the case of a read operation, the slave also drives the line to a logic-low state before sending the requested data.

If the host initiates a read and does not receive data within a specified interval of time (that is, the slave does not drive the line low within this interval), the [HDQ.HDQ\\_INT\\_STATUS\[0\] TIMEOUT](#) bit is set, thereby indicating a read failure. The TIMEOUT bit remains set until the host reads the interrupt status register ([HDQ.HDQ\\_INT\\_STATUS](#)).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out on a transaction. The corresponding bit is set in the interrupt status register ([HDQ.HDQ\\_INT\\_STATUS](#)). This register is cleared as soon as it is read.

Only one interrupt signal is sent to the MPU, and only an overall mask can enable or disable the interrupts. These interrupts cannot be individually masked.

### 23.2.3.6.3 Single-Bit Mode

In HDQ mode, the single-bit mode (HDQ.HDQ\_CTRL\_STATUS[7] ONE\_WIRE\_SINGLE\_BIT bit set to 1) has no effect because the HDQ protocol supports only byte transfers.

### 23.2.3.6.4 Interrupt Conditions

The HDQ/1-Wire provides the following interrupt status:

- **Transmission complete:**  
A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in HDQ protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ\_INT\_STATUS).
- **Read complete:**  
In HDQ mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ\_INT\_STATUS).
- **Presence detect/time-out:**  
In HDQ mode, the interrupt status indicates that after a read command initiated by the host, the slave did not pull the line low within the specified time. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ\_INT\_STATUS).  
In HDQ mode, a time-out condition is also used to indicate the successful completion of a break pulse. That is, if the master has sent the break pulse, it is indicated with a time-out instead of a TX-complete.

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all the interrupt status bits that were previously set.

### 23.2.3.7 1-Wire Mode

#### 23.2.3.7.1 1-Wire Mode Features

The 1-Wire mode supports the following:

- Dallas Semiconductor 1-Wire protocol
- Power-down mode
- Single-bit mode

#### 23.2.3.7.2 Description

The 1-Wire mode requires an initialization pulse to be sent to the slave(s) connected on the interface. If a slave is present, it responds with a presence pulse.

The initialization pulse is sent when the HDQ.HDQ\_CTRL\_STATUS[2] INITIALIZATION bit is set and the HDQ\_CTRL\_STATUS[4] GO bit is set afterwards.

When the slave receives the initialization pulse, it sends back its presence pulse by pulling down the line for a defined duration. The module detects this low-going edge and sets the HDQ.HDQ\_CTRL\_STATUS[3] PRESENCEDETECT bit.

In a similar way, if a presence pulse is not received from the slave after an initialization pulse is sent, the PRESENCEDETECT bit remains cleared.

Whether or not a presence pulse is detected after an initialization pulse is sent, the HDQ.HDQ\_INT\_STATUS[0] TIMEOUT bit is set and an interrupt condition is generated.

In 1-Wire mode, the generated interrupt condition means the maximum time allowed for receiving the response has elapsed and the software must check the PRESENCEDETECT bit to determine whether or not there was a presence pulse.

The INITIALIZATION bit is cleared at the end of the initialization pulse at the same time as the TIMEOUT bit is set. The TIMEOUT bit is cleared when the interrupt status register (HDQ.HDQ\_INT\_STATUS) is read.

For read operations, 1-Wire is a bit-by-bit protocol, which means the slave must be clocked by the host for each bit of the byte to read.

The line is pulled up at the end of the command/address byte. On the first read, the host creates a low-going edge to initiate a bit read. The line is then pulled up (pulled to the high-impedance state by the host and set to a high logical level by the external pullup) and the slave either drives the line low to transmit a 0, or does not drive the line to transmit a 1. This sequence is repeated for each bit to read.

The first bit the host receives is the LSB, and the last bit is the most-significant bit (MSB) in the receive data register (HDQ.HDQ\_RX\_DATA).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition (that is, the time allowed for the slave to indicate its presence has elapsed). A read operation on the interrupt status register clears the interrupt conditions previously set. As in the HDQ mode, only one interrupt signal is sent to the MPU. Only an overall mask bit can enable or disable the interrupt (the interrupt conditions cannot be masked individually).

#### 23.2.3.7.3 1-Wire Single-Bit Mode Operation

A single-bit mode can be entered by setting the appropriate bit in the control and status register (ONE\_WIRE\_SINGLE\_BIT bit HDQ.HDQ\_CTRL\_STATUS[7]). In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, an interrupt is generated (that is, there is an RX-complete for a read operation and a TX-complete for a write operation). The ONE\_WIRE\_SINGLE\_BIT bit is cleared by hardware after every single bit is received. Software must set this bit to re-enable reception in single-bit mode. Bit 0 of the RX register (HDQ.HDQ\_RX\_DATA) is updated each time a bit is received from the slave; bit 0 of the TX register (HDQ.HDQ\_TX\_DATA) contains the bit to be sent.

### 23.2.3.7.4 Interrupt Conditions

The HDQ/1-Wire provides the following interrupt status:

- **Transmission complete:**  
A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in 1-Wire protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ\_INT\_STATUS).
- **Read complete:**  
In 1-Wire mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ\_INT\_STATUS).
- **Presence detect/time-out:**  
In 1-Wire mode, the interrupt status indicates that it is now valid to check the PRESENCEDETECT bit. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ\_INT\_STATUS).

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all interrupt status bits that were previously set.

### 23.2.3.7.5 Status Flags

The presence-condition-detected status flag is contained in the HDQ.HDQ\_CTRL\_STATUS[3] PRESENCEDETECT bit. This is valid only in 1-Wire mode. The flag is updated when the HDQ.HDQ\_INT\_STATUS[0] TIMEOUT bit is set. Therefore, its correct value shows only after the interrupt is generated. The firmware must wait for the time-out condition; otherwise, the flag keeps its previous value and is undefined.

After the first successful presence detection, before a new 1-Wire initialization is performed, the user must execute a software reset on the HDQ/1-Wire module. This ensures a proper new initialization sequence in 1-Wire mode.

## 23.2.4 HDQ/1-Wire Integration

Figure 23-50 shows HDQ/1-Wire integration in the device.

Figure 23-50. HDQ/1-Wire Integration

Table 23-104 through Table 23-106 summarize the integration of the module in the device.

**Table 23-104. Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
HDQ/1-Wire	DPLL_PER	No	L4_PER

**Table 23-105. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
HDQ/1-Wire	HDQ_ICLK	PER_L4_ICLK	PRCM	Interface clock
HDQ/1-Wire	HDQ_FCLK	12M_FCLK	PRCM	Functional clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
HDQ/1-Wire	HDQ_RESET	L4_PER_RST	PRCM	HDQ/1-wire reset signal

**Table 23-106. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
HDQ/1-Wire	HDQ_IRQ	MA_IRQ_58	Cortex-A9	Interrupt to the Cortex A9 MPU subsystem interrupt controller (INTC).

**NOTE:** For the description of the interrupt source, see [Section 17.4.1, Cortex-A9 MPU INTC Functional Description](#), in [Chapter 17, Interrupt Controllers](#).

### 23.2.5 HDQ/1-Wire Programming Models

This section describes the low-level hardware programming sequences for configuration and usage of the module. The basic protocol functions, such as slave initialization (reset), read-byte, and write-byte operations, are described. For a description of the functions, see the HDQ/1-Wire protocol documentation.

#### 23.2.5.1 Global Initialization

##### 23.2.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the HDQ/1-Wire module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the HDQ/1-Wire. Refer to the HDQ/1-Wire Module Integration and Environment Sections for further information.

**Table 23-107. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information about the module configuration, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Control Module	Module specific pad muxing and pullup must be set in the control module. For more information about the module configuration, see <a href="#">Chapter 18, Control Module</a> .
MPU INTC	MPU INTC configuration must be done to enable the interrupts from HDQ/1-Wire module. See <a href="#">Section 17.4.1, Cortex-A9 MPU INTC Functional Description</a> , in <a href="#">Chapter 17, Interrupt Controllers</a> .

##### 23.2.5.1.2 HDQ/1-Wire Module Global Initialization

**Table 23-108. HDQ/1-Wire Module Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Initiate software reset.	<a href="#">HDQ_SYSCONFIG[1]</a> SOFTRESET	0x1
Disable power-down mode.	<a href="#">HDQ_CTRL_STATUS[5]</a> CLOCKENABLE	0x1
Wait until reset complete?	<a href="#">HDQ_SYSSTATUS[0]</a> RESETDONE	= 0x1

**Table 23-108. HDQ/1-Wire Module Global Initialization (continued)**

Step	Register/Bit Field/Programming Model	Value
Disable power-down mode.	HDQ_CTRL_STATUS[5] CLOCKENABLE	0x1
Configure auto-idle mode.	HDQ_SYSCONFIG[0] AUTOIDLE	x

### 23.2.5.2 HDQ Operational Modes Configuration

#### 23.2.5.2.1 Main Sequence – HDQ Write Operation Mode

**Table 23-109. HDQ Mode Selection**

Step	Register/Bit Field/Programming Model	Value
Select HDQ mode.	HDQ_CTRL_STATUS[0] MODE	0x0
Enable interrupt generation.	HDQ_CTRL_STATUS[6] INTERRUPTMASK	0x1
Initialize HDQ slave.	See Section 23.2.5.2.2.1	

**Table 23-110. HDQ Write Operation Mode**

Step	Register/Bit Field/Programming Model	Value
Write command/address or data value.	HDQ_TX_DATA[7:0]	0x–
Select write operation.	HDQ_CTRL_STATUS[1] DIR	0x0
Start operation.	HDQ_CTRL_STATUS[4] GO	0x1
Wait for interrupt.		
Reading HDQ_INT_STATUS clears interrupt conditions.	HDQ_INT_STATUS[2] TXCOMPLETE	0x1

#### 23.2.5.2.2 Main Sequence - HDQ Read Operation Mode

##### 23.2.5.2.2.1 Sub-sequence - Initialize HDQ Slave

**Table 23-111. HDQ Read Operation Mode**

Step	Register/Bit Field/ Programming Model	Value
Select read operation.	HDQ_CTRL_STATUS[1] DIR	0x1
Start operation.	HDQ_CTRL_STATUS[4] GO	0x1
Wait for interrupt.		
Read and store HDQ_INT_STATUS. Reading HDQ_INT_STATUS clears interrupt conditions.	HDQ_INT_STATUS	0x-
IF: Read operation successful?	HDQ_INT_STATUS[1] RXCOMPLETE	= 0x1
	HDQ_INT_STATUS[0] TIMEOUT	= 0x0
Get received data.	HDQ_RX_DATA[7:0]	0x-
ENDIF		

**Table 23-112. Initialize HDQ Slave**

Step	Register/Bit Field/Programming Model	Value
Send Initialization Pulse	HDQ_CTRL_STATUS[2] INITIALIZATION	0x1
Send Command	HDQ_CTRL_STATUS[4] GO	0x1

### 23.2.5.3 1-Wire Operational Modes Configuration

#### 23.2.5.3.1 Main Sequence - 1-Wire Write Operation Mode

**Table 23-113. 1-Wire Mode Selection**

Step	Register/Bit Field/Programming Model	Value
Reset HDQ/1-Wire module.	See <a href="#">Section 23.2.5.1.2</a> .	
Select 1-Wire mode.	HDQ_CTRL_STATUS[0] MODE	0x1
Enable interrupt generation.	HDQ_CTRL_STATUS[6] INTERRUPTMASK	0x1
Initialize 1-Wire slave, check for slave presence.	See <a href="#">Section 23.2.5.3.3</a> .	

**Table 23-114. 1-Wire Write Operation Mode**

Step	Register/Bit Field/ Programming Model	Value
Write ID/command or data value.	HDQ_TX_DATA[7:0]	0x–
Select write operation.	HDQ_CTRL_STATUS[1] DIR	0x0
Start operation.	HDQ_CTRL_STATUS[4] GO	0x1
Wait for interrupt.		
Reading <a href="#">HDQ_INT_STATUS</a> clears interrupt conditions.	HDQ_INT_STATUS[2] TXCOMPLETE	0x1

### 23.2.5.3.2 Main Sequence - 1-Wire Read Operation Mode

**Table 23-115. 1-Wire Read Operation Mode**

Step	Register/Bit Field/Programming Model	Value
Select read operation.	HDQ_CTRL_STATUS[1] DIR	0x1
Start operation.	HDQ_CTRL_STATUS[4] GO	0x1
Wait for interrupt.		
Read and store <a href="#">HDQ_INT_STATUS</a> . Reading <a href="#">HDQ_INT_STATUS</a> clears interrupt conditions.	HDQ_INT_STATUS	0x–
IF: Read operation successful?	HDQ_INT_STATUS[1] RXCOMPLETE	= 0x1
Get received data.	HDQ_RX_DATA[7:0]	0x–
ENDIF		

### 23.2.5.3.3 Sub-sequence - Initialize 1-Wire Slave

**Table 23-116. Initialize 1-Wire Slave**

Step	Register/Bit Field/Programming Model	Value
Select sending initialization pulse operation.	HDQ_CTRL_STATUS[2] INITIALIZATION	0x1
Start operation.	HDQ_CTRL_STATUS[4] GO	0x1
Wait for interrupt.		
IF: Presence pulse detected?	HDQ_INT_STATUS[0] TIMEOUT	= 0x1
	HDQ_CTRL_STATUS[3] PRESENCEDETECT	= 0x1
Slave is present and initialized.		
ELSE		
Repeat initialization subsequence.		
ENDIF		

## 23.2.6 HDQ/1-Wire Register Manual

### 23.2.6.1 HDQ/1-Wire Instance Summary

**Table 23-117. HDQ/1-Wire Instance Summary**

Module Name	Base Address	Size
HDQ/1-Wire	0x480B 2000	4KB

**23.2.6.2 HDQ/1-Wire Registers****CAUTION**

The following rules must be observed when accessing the module registers:

- A read from the [HDQ\\_INT\\_STATUS](#) register or the [HDQ\\_RX\\_DATA](#) register is not allowed unless the processor has been interrupted by the module.
- After the release of the GO bit in the [HDQ\\_CTRL\\_STATUS](#) register, no access to the [HDQ\\_TX\\_DATA](#) or [HDQ\\_CTRL\\_STATUS](#) register is allowed until the processor has been interrupted by the module.
- Polling of the [HDQ\\_INT\\_STATUS](#) register by software to determine whether an interrupt was generated is not allowed.

**CAUTION**

The HDQ/1-Wire registers are limited to 32-bit data accesses; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.

**23.2.6.2.1 HDQ/1-Wire Register Summary****Table 23-118. HDQ/1-Wire Registers Mapping Summary**

### 23.3 UART/IrDA/CIR

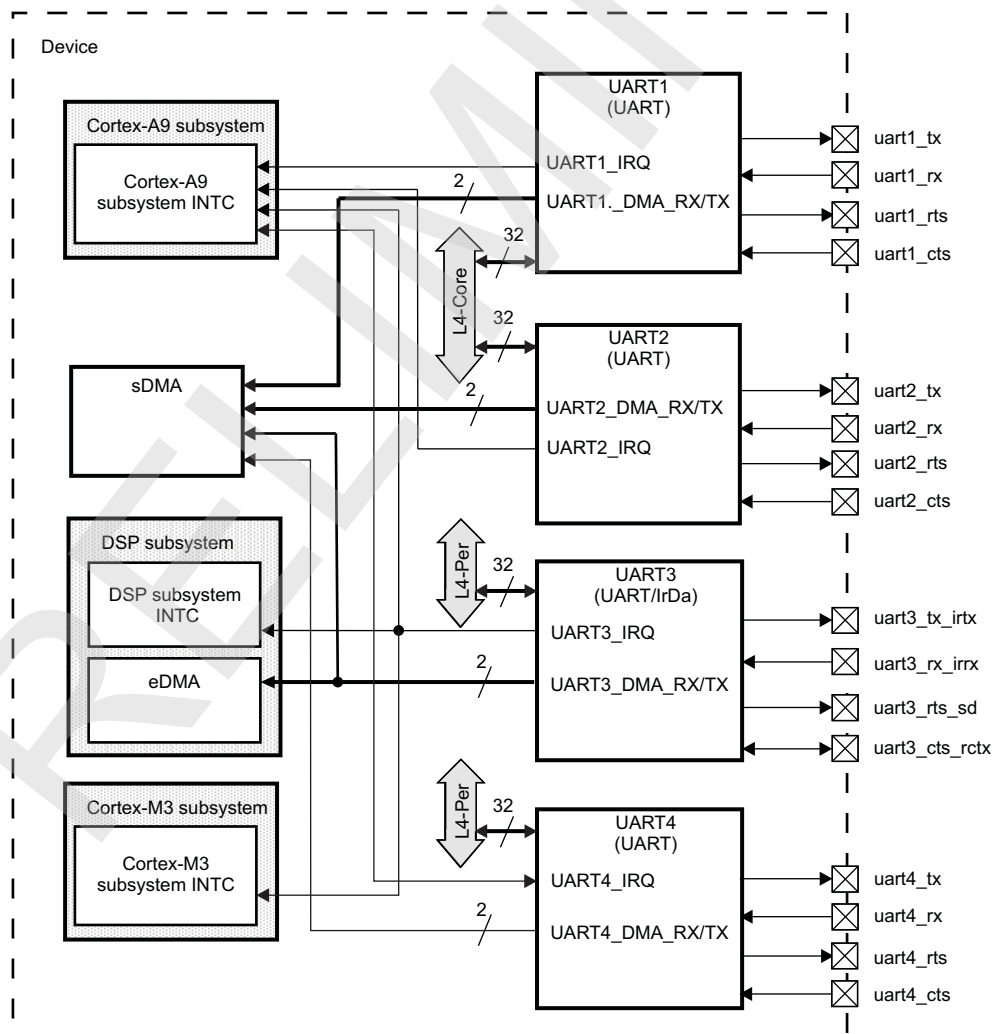

This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART)/infrared data association (IrDA)/consumer infrared (CIR) module in the device.

#### 23.3.1 UART/IrDA/CIR Overview

The device contains four universal asynchronous receiver/transmitter (UART) devices controlled by the microprocessor unit (MPU) (see [Figure 23-51](#)):

- Three UART-only modules, UART1, UART2, and UART4, are pinned out for use as UART devices only.
- UART3, which adds infrared communication support, is pinned out for use as a UART, infrared data association (IrDA), or consumer infrared (CIR) device, and can be programmed to any available operating mode.

**Figure 23-51. UART Module**

uart-001

### 23.3.1.1 UART Features

The UARTs (UART1, UART2, UART3 when in UART mode, and UART4) include the following key features:

- 16C750 compatibility
- 64-byte first in first out (FIFO) buffer for receiver and 64-byte FIFO for transmitter
- Programmable interrupt trigger levels for FIFOs
- Baud generation based on programmable divisors N (N = 1...16,384) operating from a fixed functional clock of 48 MHz

Oversampling is programmed by software as 16 or 13; thus, the baud rate computation is one of two options:

- Baud rate = (functional clock/16)/N
- Baud rate = (functional clock/13)/N

This software programming mode enables higher baud rates with the same error amount without changing the clock source:

- Break character detection and generation
- Configurable data format:
  - Data bit: 5, 6, 7, or 8 bits
  - Parity bit: Even, odd, none
  - Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)

The UART clocks are connected to produce a baud rate of up to 3.6 mbps. [Table 23-133](#) lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

**Table 23-133. UART Mode Baud Rates, Divisor Values, and Error Rates**

Baud Rate	Oversampling	Divisor	Error (%)
300	16	10,000	0
600	16	5000	0
1200	16	2500	0
2400	16	1250	0
4800	16	625	0
9600	16	312	0.16
14,400	16	208	0.16
19,200	16	156	0.16
28,800	16	704	0.16
38,400	16	78	0.16
57,600	16	52	0.16
115,200	16	26	0.16
230,400	16	13	0.16
460,800	13	8	0.16
921,600	13	4	0.16
1,843,200	13	2	0.16
3,000,000	16	1	0
3,686,400	13	1	0.16

### 23.3.1.2 IrDA Features

The IrDA (UART3 only) includes the following key features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications:
  - Frame formatting: Addition of variable beginning-of-frame (xBOF) characters and end-of-frame

- (EOF) characters
- Uplink/downlink cyclic redundancy check (CRC) generation/detection
  - Asynchronous transparency (automatic insertion of break character)
  - Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
  - Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection

Table 23-134 lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

**Table 23-134. UART IrDA Mode Baud Rates, Divisor Values, and Error Rates**

Baud Rate	IR Mode	Encoding	Divisor	Error (%)
2400	SIR	3/16	1250	0
9600	SIR	3/16	312	0.16
19,200	SIR	3/16	156	0.16
38,400	SIR	3/16	78	0.16
57,600	SIR	3/16	52	0.16
115,200	SIR	3/16	26	0.16
576,000	MIR	1/4	2	0
1,152,000	MIR	1/4	1	0
4,000,000	FIR	4 PPM <sup>(1)</sup>	1	0

<sup>(1)</sup> PPM = pulse-position-modulation

### 23.3.1.3 CIR Features

CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable  $t$  period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR (UART3 only) includes the following key features to provide CIR support for remote-control applications:

- Transmit mode only (receive mode is not supported)
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle

### 23.3.2 UART/IrDA/CIR Environment

This section describes the UART/IrDA/CIR connection with an external device.

#### 23.3.2.1 System Using UART Communication With Hardware Handshake

Each UART instance can be connected easily to the UART port of an external integrated circuit (IC) (see [Figure 23-52](#)).

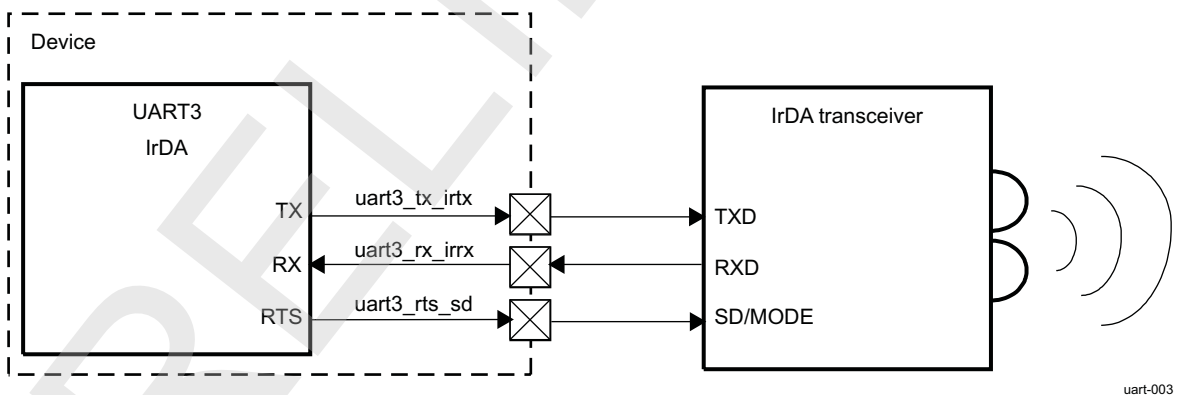

**Figure 23-52. UART Mode Bus System Overview**

#### 23.3.2.2 System Using IrDA Communication Protocol

As [Figure 23-53](#) shows, UART3 can be connected to an external infrared transceiver in the IrDA modes (FIR, SIR, and MIR).

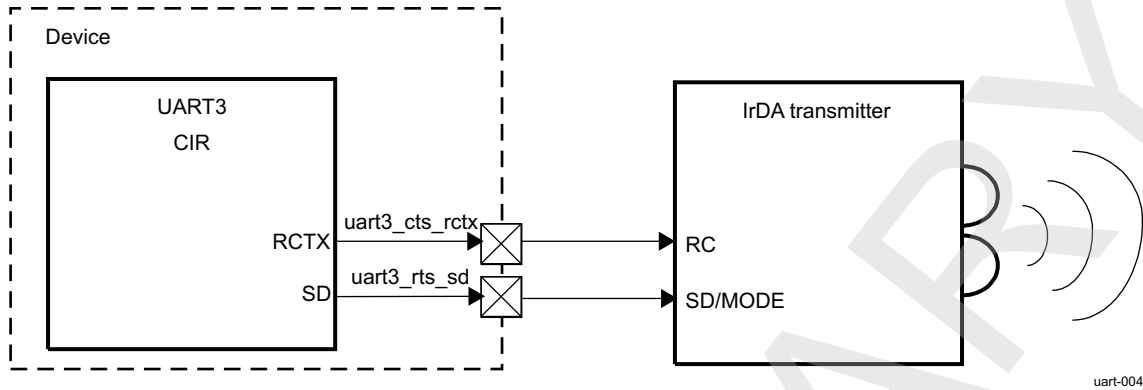

**Figure 23-53. IrDA System Overview**

#### 23.3.2.3 System Using CIR Communication Protocol With Remote Control

UART3 can be connected to an external Infrared transceiver in CIR mode (see [Figure 23-54](#)).

Figure 23-54. CIR System Overview

### 23.3.2.4 UART Interface

#### 23.3.2.4.1 Description

Table 23-135 lists the UART interface input/output (I/O) signals.

Table 23-135. UART I/O Pins

Signal	I/O <sup>(1)</sup>	Description	Reset
<b>UART Modem Signals</b>			
uarti_rx	I	Serial data input	Unknown
uarti_tx	O	Serial data output	1
		Because this pin is active high in IrDA mode and the output is muxed, this pin is set to low on reset (when the UARTi.UART_MDR1[2:0] bit field is set to 0x7) and takes the defined inactive level of that signal corresponding to when and how the UARTi.UART_MDR1 register is programmed; that is, the output is 1 (inactive for UART modem modes) and 0 (inactive for IrDA modes).	
uarti_cts	I	Clear to send	Unknown
		Active-low modem status signal. Reading the UARTi.UART_MSR[4] NCTS_STS bit checks the condition of uarti_cts. Reading the UARTi.UART_MSR[0] CTS_STS bit checks a change of state of uarti_cts since the last read of the modem status register. The auto-nCTS mode uses uarti_cts to control the transmitter.	
uarti_rts	O	Request to send	1
		When active (low), the module is ready to receive data. Setting the UARTi.UART_MCR[1] RTS bit activates uarti_rts, which becomes inactive as the result of a module reset, loopback mode, or clearing the UARTi.UART_MCR[1] RTS bit. In auto-RTS mode, uarti_rts becomes inactive as a result of the receiver threshold logic.	

<sup>(1)</sup> I = Input; O = Output

#### 23.3.2.4.2 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16x (<= 230.4 kbps)
- UART 16x with autobauding (>= 1200 bps and >= 115.2 kbps)
- UART 13x (>= 460.8 kbps)

**CAUTION**

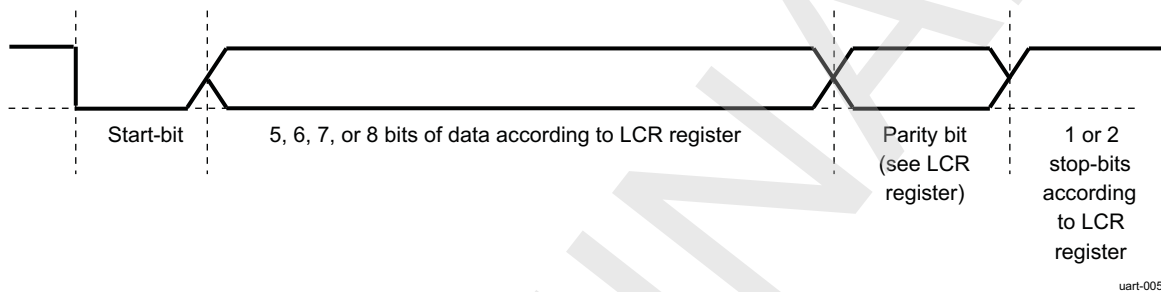

To be used as a UART, the operating mode must be programmed appropriately in the UARTi.UART\_MDR1[2:0] MODE\_SELECT bit field to select UART, IrDA, or CIR mode.

The UART uses a wired interface for serial communication with a remote device.

The UART is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

Figure 23-55 shows the UART frame data format.

**Figure 23-55. UART Frame Data Format**

### 23.3.2.5 IrDA Functional Interfaces

#### 23.3.2.5.1 UART3 Interface Description

Table 23-136 lists the UART3 interface I/O signals.

**Table 23-136. UART3 I/O Signals**

Signal	I/O <sup>(1)</sup>	Description	Reset
<b>IrDA Signals</b>			
uart3_rx_irrx	I	Serial data input	Unknown
uart3_tx_irtx	O	Serial data output in IrDA modes (SIR, MIR, and FIR). In other modes, this pin is set to the reset value (inactive state).	0
uart3_rts_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.UART_ACREG[6] SD_MOD bit.	1

<sup>(1)</sup> I = Input; O = Output

### 23.3.2.5.2 IrDA Protocol and Data Format

#### 23.3.2.5.2.1 SIR Mode

In SIR mode, data is transferred between the MPU and peripheral devices at speeds of up to 115,200 baud. A SIR transmit frame begins with start flags (a single 0xC0, a multiple 0xC0, or a single 0xC0 preceded by a number of 0xFF flags), is followed by frame data and a CRC-16, and ends with a stop flag (0xC1).

The bit format for a single word uses 1 start-bit, 8 data bits, and 1 stop-bit, and is unaffected by the use and settings of the UART3.UART\_LCR register.

The UART3.UART\_BLR[6] XBOF\_TYPE bit selects whether the 0xC0 or 0xFF start patterns are used when multiple start flags are required.

The SIR transmit state-machine attaches start flags, CRC-16, and stop flags, and checks the outgoing data to establish whether data transparency is required.

SIR transparency is carried out if the outgoing data between the start and stop flags contains 0xC0, 0xC1, or 0x7D. If one of these start flags is about to be transmitted, the SIR state-machine first sends an escape character (0x7D), then inverts the fifth bit of the real data to be sent, and sends this data immediately after the 0x7D character.

The SIR receive state-machine recovers the receive clock, removes the start flags and any transparency from the incoming data, and determines the frame boundary with reception of the stop flag. The SIR state-machine also checks for errors such as a frame abort (0x7D character followed immediately by a 0xC1 stop flag without transparency), a CRC error, or a frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART\_LSR) to find possible errors of the received frame.

---

**NOTE:** The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See the description of the UART3.UART\_ACREG[5] DIS\_IR\_RX bit. This applies to all three modes: SIR, MIR, and FIR.

---

Infrared output in SIR mode can be 1.6- $\mu$ s or 3/16 encoding, selected by the UART3.UART\_ACREG[7] PULSE\_TYPE bit. In 1.6- $\mu$ s encoding, the infrared pulse width is 1.6  $\mu$ s; and in 3/16th encoding, the infrared pulse width is 3/16th of a bit duration (1/ baud rate).

For back-to-back frames, the transmitting device must send at least two start flags at the start of each frame.

---

**NOTE:** Reception supports variable-length stop-bits.

---

#### 23.3.2.5.2.1.1 Frame Format

Figure 23-56 shows the IrDA SIR frame format.

**Figure 23-56. IrDA SIR Frame Format**

uart-006

The CRC is applied on the address (A), control (C), and information (I) bytes.

---

**NOTE:** The two words of CRC are written to the FIFO in reception.

---

#### 23.3.2.5.2.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to 0xC0 (BOF), 0xC1 (EOF), or 0x7D (control escape), the controller performs certain tasks:

- In transmission:

- Inserts a control escape (CE) byte preceding the byte
- Complements bit 5 of the byte (that is, exclusive ORs the byte with 0x20)

The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 0x20).

- In reception:

For the A, C, I, CRC field:

- Compares the byte with the CE byte; if they are not equal, sends the byte to the CRC detector and stores it in the RX FIFO
- If the byte is equal to the CE byte, discards the CE byte
- Complements bit 5 of the byte following the CE
- Sends the complemented byte to the CRC detector and stores it in the RX FIFO

#### 23.3.2.5.2.1.3 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

When a 0x7D character followed immediately by a 0xC1 character is received without transparency, the receiver treats the frame as an aborted frame.

#### 23.3.2.5.2.1.4 Pulse Shaping

SIR mode supports the 3/16 and the 1.6-us pulse duration methods. The UART3.UART\_ACREG[7] PULSE\_TYPE bit selects the pulse-width method in transmit mode.

#### 23.3.2.5.2.1.5 Encoder

Serial data from the transmit state-machine are encoded to transmit data to the optoelectronics. While the TX FIFO output is high, the `uart3_tx_irtx` line is always low, and the counter used to form a pulse on `uart3_tx_irtx` is cleared continuously.

After the TX FIFO output resets to 0, `uart3_tx_irtx` rises on the falling edge of the seventh 16XCLK. On the falling edge of the tenth 16XCLK pulse, `uart3_tx_irtx` falls, creating a three-clock-wide pulse. While the TX FIFO output stays low, a pulse is transmitted during the seventh to the tenth clock of each 16-clock bit cycle.

Figure 23-57 shows the IrDA SIR encoding mechanism.

Figure 23-57. IrDA SIR Encoding Mechanism

23.3.2.5.2.1.6 Decoder

After reset, the RX FIFO input is high and the 4-bit counter is cleared. When a rising edge is detected on RX, the RX FIFO input falls on the next rising edge of 16XCLK with sufficient setup time. The RX FIFO input stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, the RX FIFO input remains high.

Figure 23-58 shows the IrDA SIR decoding mechanism.

Figure 23-58. IrDA SIR Decoding Mechanism

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. The operation of the `uart3_rx_irrx` input can be disabled using the `UART3.UART_ACREG[5] DIS_IR_RX` bit. The `UART3.UART_MDR2[6] IRRXINVERT` bit can invert the signal from the transceiver (RXD) pin to the IRRX logic in the UART. This inversion is performed by default.

### 23.3.2.5.2.1.7 IR Address Checking

In all IR modes, when address checking is enabled by setting the `UART_EFR[1:0]` bit field (see [Table 23-137](#)), only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multipoint infrared environment. To program two frame addresses that the UART3 receives in IrDA mode, use the `UART3.UART_XON1_ADDR1[7:0]` bit field and the `UART3.UART_XON2_ADDR2[7:0]` bit field.

**Table 23-137. UART\_EFR[1:0] IR Address Checking Options**

UART_EFR[1]	UART_EFR[0]	IR Address Checking
0	0	All address-checking operations disabled
0	1	Only address 1 checking enabled
1	0	Only address 2 checking enabled
1	1	All address-checking operations enabled

### 23.3.2.5.2.2 SIR Free-Format Mode

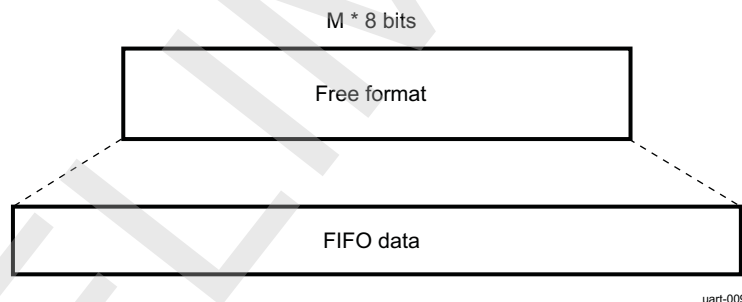

To allow complete software flexibility when transmitting and receiving infrared data packets, SIR free-format (FF) mode is a subfunction of the existing SIR mode. In FF mode, all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values.

FF mode corresponds to a UART mode with a pulse modulation of 3/16 of baud rate pulse width.

For example, a normal SIR packet has BOF control and CRC error-checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs.

[Figure 23-59](#) shows SIR FF mode.

**Figure 23-59. SIR FF Mode**

In SIR FF mode, the MPU software must construct (that is, encode and decode) the entire FIFO data packet.

### 23.3.2.5.2.3 MIR Mode

In MIR mode, data is transferred between the MPU and the peripheral devices at 0.576 or 1.152 mbps speed. A MIR transmit frame starts with at least two start flags, followed by a frame data, CRC-16, and ends with a stop flag (see [Figure 23-60](#)).

Figure 23-60. MIR Transmit Frame Format

On transmit, the MIR state-machine attaches start flags, CRC-16, and stop flags, as in SIR mode. All fields are transmitted least-significant bit (LSB) of each byte first.

In MIR mode:

- The state-machine looks for consecutive 1s in the frame data and automatically inserts 0 after five consecutive 1s (this is called bit-stuffing).
- 0x7E is used for start and stop flags (unambiguously, not data, because of bit-stuffing).
- An abort sequence requires a minimum of seven consecutive 1s (unambiguously, not data, because of bit-stuffing).
- Back-to-back frames are allowed with three or more stop flags between them. If two consecutive frames are not back to back, the gap between the last stop flag of the first frame and the start flag of the second frame must be separated by at least seven bit durations.

On receive, the MIR receive state-machine recovers the receive clock, removes the start flags, destuffs the incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as frame abort, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART\_LSR) to detect errors of the received frame.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

### 23.3.2.5.2.3.1 MIR Encoder/Decoder

To meet the MIR baud rate tolerance of 0.1 percent with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag, and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected.

The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4, but it is within the tolerances defined by IrDA specifications.

Figure 23-61 shows the MIR baud rate adjustment mechanism.

**Figure 23-61. MIR Baud Rate Adjustment Mechanism**

uart-011

**23.3.2.5.2.3.2 SIP Generation**

In the MIR and FIR operation modes, the transmitter must send a serial infrared interaction pulse (SIP) at least once every 500 ms. The SIP informs slow devices (operating in SIR mode) that the medium is occupied.

Figure 23-62 shows the SIP.

**23.3.2.5.2.4 FIR Mode**

In FIR mode, data is transferred between the MPU and the peripheral devices at 4 Mbps. A FIR transmit frame starts with a preamble that is followed by a start flag, frame data, CRC-32, and ends with a stop flag.

Figure 23-63 shows the FIR transmit frame format.

**Figure 23-63. FIR Transmit Frame Format**

Preamble (16x)	Start flag	Frame data	CRC-32	Stop flag
----------------	------------	------------	--------	-----------

On transmit, the FIR transmit state-machine attaches the preamble, start flag, CRC-32, and stop flag. An abort sequence requires at least two transmissions of 0000. Back-to-back frames are allowed, but each frame must be complete.

The state-machine also encodes the transmit data into 4-PPM format (see Table 23-138) and generates the SIP (see Section 23.3.2.5.2.3.2, SIP Generation).

**Table 23-138. 4-PPM Format**

Data Bit Pair (Bin)	4-PPM Data Symbol (Bin)
00	1000
01	0100
10	0010
11	0001

The four symbols described in Table 23-138 are the legal encoded data symbols. All other combinations are illegal for encoding data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag because they are unambiguously not data (see Table 23-139).

**Table 23-139. FIR Preamble, Start Flag, and Stop Flag**

Frame Part	Transmitted Frame (Bin)
Preamble	1000 0000 1010 1000 (16 repeated transmissions)
Start flag	0000 1100 0000 1100 0110 0000 0110 0000
Stop flag	0000 1100 0000 1100 0000 0110 0000 0110

All fields are transmitted the LSBs of each byte first (see [Table 23-140](#)).

**Table 23-140. FIR Data Byte Transmission Order Example**

Data Byte (Hex)	Data Byte Pair (Bin)	4-PPM Data Symbol (Bin)	Transmission Order
0x0B	00	1000	4
	00	1000	3
	10	0010	2
	11	0001	1

On receive, the FIR receive state-machine recovers the receive clock, removes the preamble and the start flag, decodes the 4-PPM incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as illegal symbol, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART\_LSR) to detect errors of the received frame.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

### 23.3.2.6 CIR Functional Interfaces

#### 23.3.2.6.1 CIR Interface Description

[Table 23-141](#) lists the CIR interface I/O signals.

**Table 23-141. CIR I/O Signals**

Signal	I/O <sup>(1)</sup>	Description	Reset
<b>CIR Signals</b>			
uart3_rx_irrx	I	Serial data input	Unknown
uart3_cts_rctx	O	Serial data output in CIR mode. In other modes, this pin is set to the reset value (inactive state).	0
uart3_rts_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.UART_ACREG[6] SD_MOD bit.	1

<sup>(1)</sup> I = Input; O = Output

#### 23.3.2.6.2 CIR Protocol and Data Format

In CIR mode, the infrared operation functions as a programmable (universal) remote control.

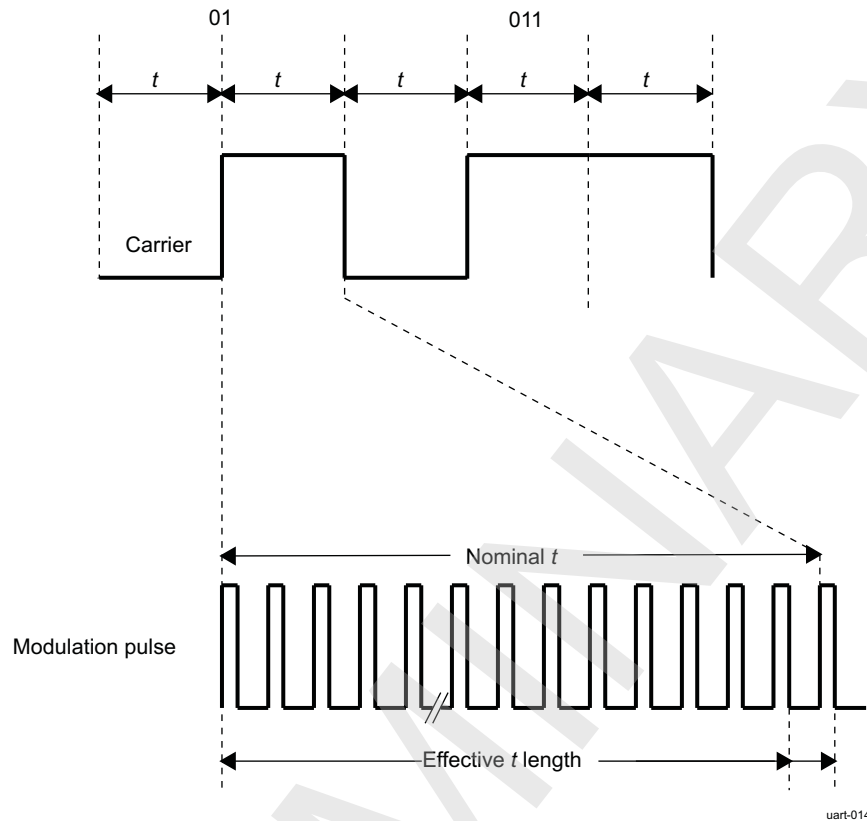

CIR mode uses a variable PWM technique (based on multiples of a programmable  $t$  period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on user-defined frame structure and packet content.

##### 23.3.2.6.2.1 Carrier Modulation

Each modulated pulse that constitutes a digit is a train of on/off pulses (see [Figure 23-64](#)).

Figure 23-64. CIR Pulse Modulation

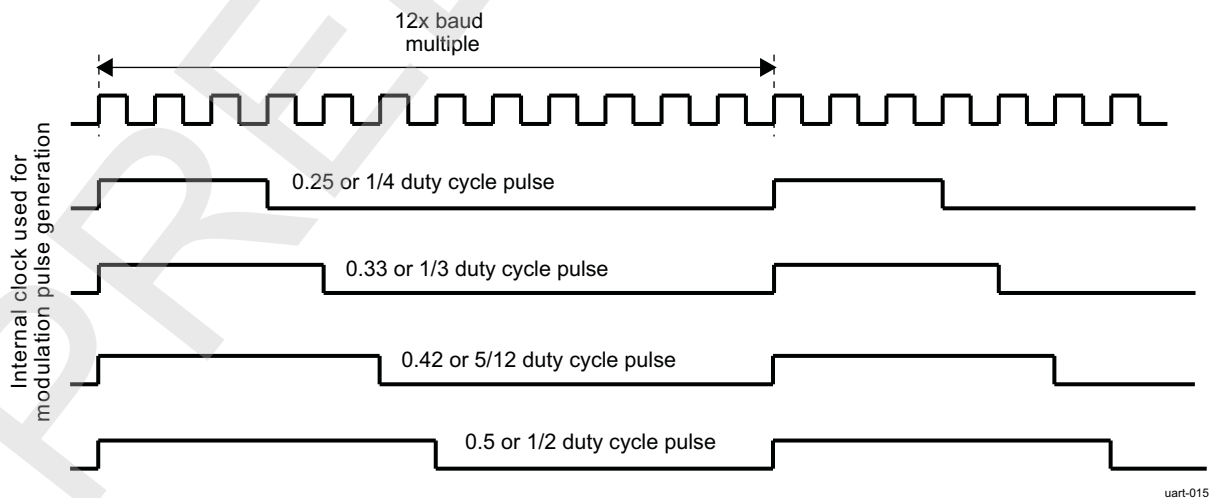

### 23.3.2.6.2.2 Pulse Duty Cycle

The programmer can choose one of four duty cycles for modulation pulses by setting the appropriate value in the UART3.UART\_MDR2[5:4] CIR\_PULSE\_MODE bit field (1/4, 1/3, 5/12, or 1/2).

Figure 23-65 shows the CIR modulation duty cycles.

Figure 23-65. CIR Modulation Duty Cycle

The transmission logic ensures that all pulses are transmitted completely (no cutoff during transmission). While transmitting continuous bytes back-to-back, no delay is inserted between 2 transmitted bytes. Thus, software must handle the delay between consecutively transmitted bytes if the receiving end requires it.

### 23.3.2.6.2.3 Consumer IR Encoding/Decoding

There are two methods of encoding for remote-control applications:

- Pulse duration encoding (time-extended bit forms): A variable pulse distance, or duration, in which the difference between logic 1 and logic 0 is the length of the pulse width
- Biphase encoding: The encoding of logic 0 and logic 1 is in the change of signal level from 1 to 0 or 0 to 1, respectively.

Japanese manufacturers favor pulse duration encoding; European manufacturers favor biphase encoding.

CIR mode uses a completely flexible free-format encoding in which 1 is transmitted from the TX FIFO as a modulated pulse with duration  $T$ .

Similarly, 0 is transmitted as a blank duration  $T$ . The MPU constructs and deciphers the protocol of the data. For example, the RC-5 protocol using Manchester encoding can be emulated as using a 01 pair for 1 and a 10 pair for 0 (see [Figure 23-66](#)).

**Figure 23-66. RC-5 Bit Encoding**

Because CIR mode logic does not impose a fixed format for infrared packets of data, the MPU software can define the format using simple data structures that are then modulated into an industry standard, such as RC-5 or SIRC. To send a sequence of 0101 in RC-5, the MPU software must write an 8-bit binary character of 10011001 to the data FIFO of the UART.

For SIRC, the modulation length (multiples of  $T$ ) is used to distinguish between 1 and 0. The subsequent SIRC digits show the difference in encoding between this and, for example, RC-5. The pulse width is extended for one digit.

[Figure 23-67](#) shows SIRC bit encoding.

**Figure 23-67. SIRC Bit Encoding**

To construct comprehensive packets constituting remote-control commands, the MPU software must combine a number of 8-bit data characters in a sequence that follows one of the universally accepted formats.

Figure 23-68 shows a standard RC-5 frame as detected by UART3 in CIR mode (the SIRC format follows this). Each field in RC-5 can be considered as two T pulses (digital bits) from the TX FIFO.

**Figure 23-68. RC-5 Standard Packet Format**

uart-018

Where:

- S1, S2: Start-bits (always 1)
- T: Toggle bit
- A4..A0: Address (or system) bits
- C5..C0: Command bits

The toggle bit T changes when a new command is transmitted to detect when the same key is pressed twice (effectively receiving the same data from the host consecutively). A brief delay in the transmission of the same command is detected by the use of the toggle bit because a code is sent while the MPU transmits characters to the UART for transmission. The address bits define the machine or device for which the infrared transmission is intended, and the command defines the operation.

To accommodate an extended RC-5 format, the S2 bit is replaced by an additional command bit (C6) that lets the command range increase to 7 bits. This format is known as the extended RC-5 format.

SIRC encoding uses the duration of modulation for mark and space; therefore, the duration of data bits in the standard frame length varies.

Figure 23-69 shows the packet format and bit encoding. As Figure 23-70 shows, 1 start-bit of 2.4 ms and control codes are followed by data that constitute the entire frame.

**Figure 23-69. SIRC Packet Format**

uart-019

**NOTE:** The encoding must take a standard duration, but the contents of the data can vary. This implies that the control software for sending and receiving data packets must exercise a scheme of interpacket delay, where successive packets can be sent only after a real-time delay expires.

**Figure 23-70. SIRC Bit Transmission Example**

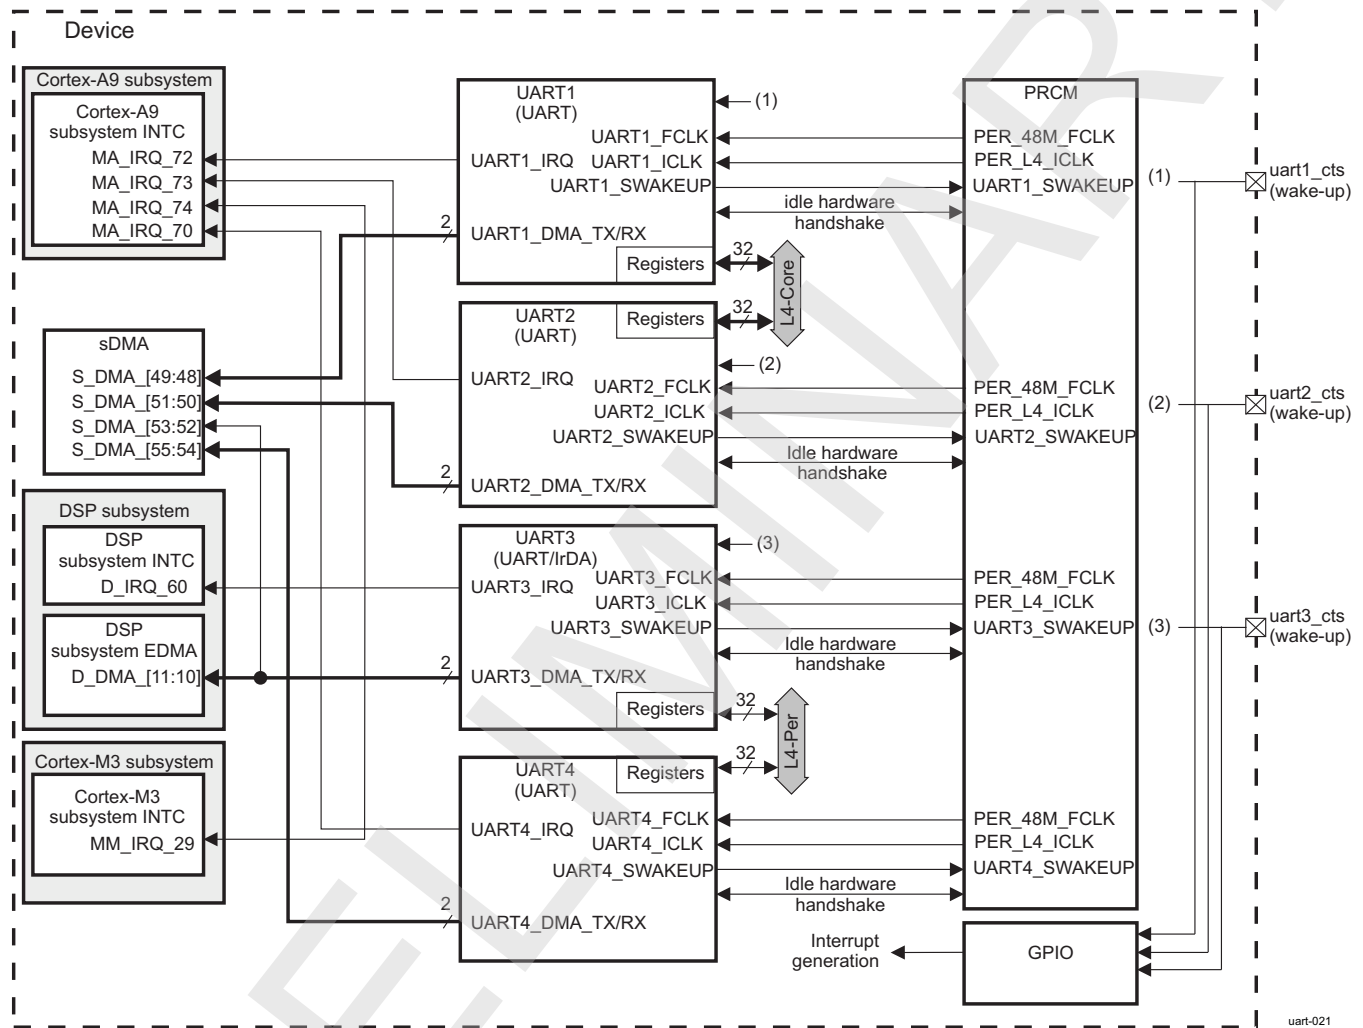

This document does not describe all encoding methods and techniques; the preceding information shows the considerations required to employ different encoding methods for different industry-standard protocols. See industry-standard documentation for specific methods of encoding and protocol use.

### 23.3.3 UART/IrDA/CIR Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 23-71 shows the device internal connections with related modules for UART functions.

Figure 23-71. UART/IrDA/CIR Integration

**NOTE:** For more information about the idle and standby hardware handshakes and the wake-up request, see Section 3.1.1.1.4, *Clock Domain Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 23-142 through Table 23-144 summarize the integration of the module in the device.

Table 23-142. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
UART1	PD_L4_PER	Yes	L4_PER
UART2	PD_L4_PER	Yes	L4_PER
UART3	PD_L4_PER	Yes	L4_PER
UART4	PD_L4_PER	Yes	L4_PER

**Table 23-143. Clocks and Resets**

Clocks				
Module Instance	Destination Signal	Source Signal	Source	Description
UART1	UART1_ICLK	PER_L4_ICLK	PRCM	UART1 interface clock
	UART1_FCLK	PER_48M_FCLK	PRCM	UART1 functional clock
UART2	UART2_ICLK	PER_L4_ICLK	PRCM	UART1 interface clock
	UART2_FCLK	PER_48M_FCLK	PRCM	UART1 functional clock
UART3	UART3_ICLK	PER_L4_ICLK	PRCM	UART3 interface clock
	UART3_FCLK	PER_48M_FCLK	PRCM	UART3 functional clock
UART4	UART4_ICLK	PER_L4_ICLK	PRCM	UART4 interface clock
	UART4_FCLK	PER_48M_FCLK	PRCM	UART4 functional clock
Resets				
Module Instance	Destination Signal	Source Signal	Source	Description
UART1	UART1_RST	L4_PER_RST	PRCM	UART1 reset signal
UART2	UART2_RST	L4_PER_RST	PRCM	UART2 reset signal
UART3	UART3_RST	L4_PER_RST	PRCM	UART3 interface reset
UART4	UART4_RST	L4_PER_RST	PRCM	UART4 reset

**Table 23-144. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal	Destination Signal	Destination	Description
UART1	UART1_IRQ	MA_IRQ_72	Cortex™-A9	UART module 1
UART2	UART2_IRQ	MA_IRQ_73	Cortex-A9	UART module 2
UART3	UART3_IRQ	D_IRQ_60	DSP	UART module 3 (also infrared)
	UART3_IRQ	MA_IRQ_74	Cortex-A9	UART module 3 (also infrared)
	UART3_IRQ	MM_IRQ_29	Cortex™-M3	UART module 3 (also infrared)
UART4	UART4_IRQ	MA_IRQ_70	Cortex-A9	UART module 4
Direct Memory Access (DMA) Requests				
Module Instance	Source Signal	Destination Signal	Destination	Description
UART1	UART1_DMA_TX	S_DMA_48	sDMA	UART module 1 – transmit request
	UART1_DMA_RX	S_DMA_49	sDMA	UART module 1 – receive request
UART2	UART2_DMA_TX	S_DMA_50	sDMA	UART module 2 – transmit request
	UART2_DMA_RX	S_DMA_51	sDMA	UART module 2 – receive request
UART3	UART3_DMA_TX	S_DMA_52	sDMA	UART module 3 – transmit request (also infrared)
	UART3_DMA_RX	S_DMA_53	sDMA	UART module 3 – receive request (also infrared)
	UART3_DMA_TX	D_DMA_10	DDMA	UART module 3 – transmit request [0]
	UART3_DMA_RX	D_DMA_11	DDMA	UART module 3 – receive request [0]
UART4	UART4_DMA_TX	S_DMA_54	sDMA	UART module 4 – transmit request
	UART4_DMA_RX	S_DMA_55	sDMA	UART module 4 – receive request

## 23.3.4 UART/IrDA/CIR Functional Description

### 23.3.4.1 Block Diagram

The UART/IrDA/CIR module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to the chosen function (UART, IrDA, or CIR) and enables the mechanism corresponding to the chosen function
- Register mode: Enables conditional access to registers

For more information about mode configuration, see [Section 23.3.4.7, Mode Selection](#).

Protocol formatting has three subcategories:

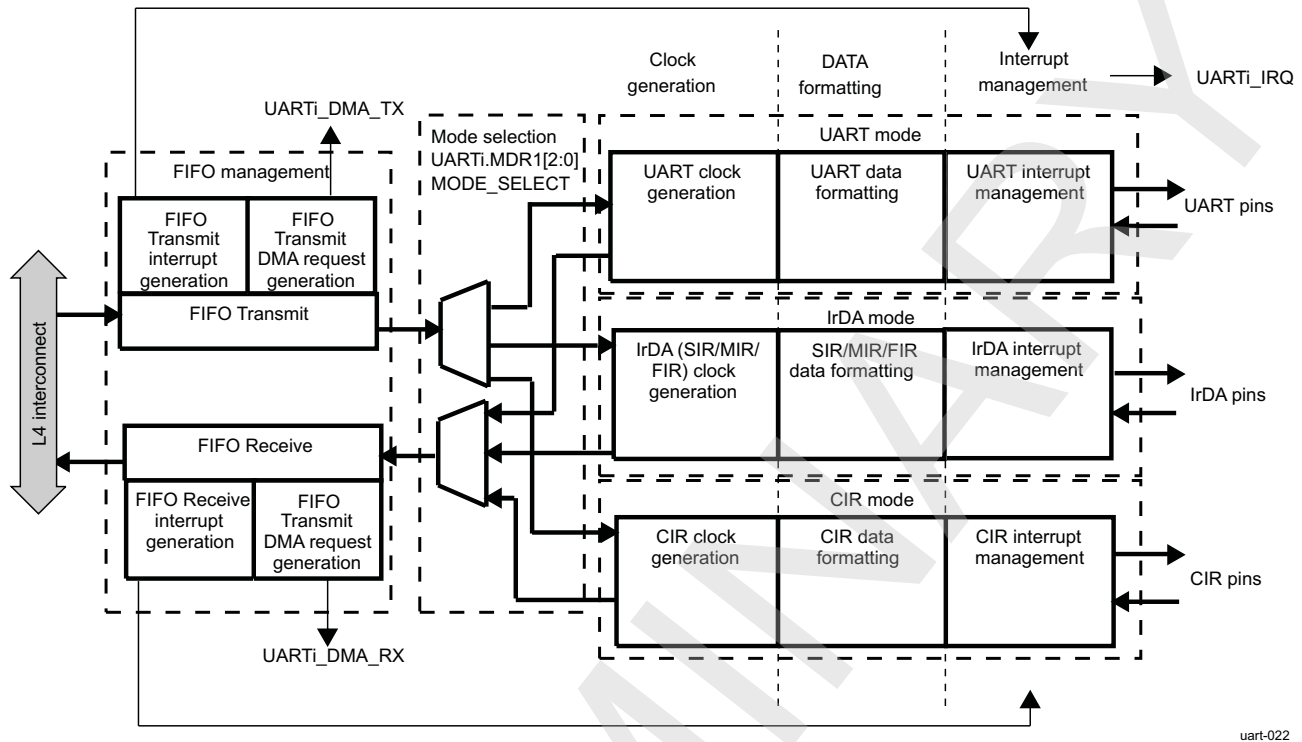

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine that is responsible for the transition between FIFO data and frame data associated with it.
- Interrupt management: Different interrupt types are generated depending on the chosen function:
  - UART mode interrupts: Seven interrupts prioritized in six different levels
  - IrDA mode interrupts: Eight interrupts. The interrupt line is activated when any interrupt is generated (there is no priority).
  - CIR mode interrupts: A subset of existing IrDA mode interrupts is used.

In each mode, when an interrupt is generated, the [UART\\_IIR](#) register indicates the interrupt type.

In parallel with these functional blocks, a power-saving strategy exists for each function.

[Figure 23-72](#) is the UART/IrDA/CIR block diagram.

Figure 23-72. UART/IrDA/CIR Functional Specification Block Diagram

uart-022

### 23.3.4.2 Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses. The power, reset, and clock management (PRCM) module generates and controls all these clocks (for more information, see [Section 3.6.4.4, Clock Domain Module Attributes](#), in [Chapter 3, Power, Reset, and Clock Management](#)).

The idle and wake-up processes use a handshake protocol between the PRCM and the UART (for a description of the protocol, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)). The UARTi.UART\_SYSC[4:3] IDLEMODE bit field controls UART idle mode.

### 23.3.4.3 Software Reset

The UARTi.UART\_SYSC[1] SOFTRESET bit controls the software reset; setting this bit to 1 triggers a software-reset functionally equivalent to hardware reset.

### 23.3.4.4 Power Management

#### 23.3.4.4.1 UART Mode Power Management

##### 23.3.4.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UARTi.UART\_IER[4] SLEEP\_MODE bit to 1 (when the UARTi.UART\_EFR[4] ENHANCED\_EN bit is set to 1).

Sleep mode is entered when all the following conditions exist:

- The serial data input line, uarti\_rx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- The only pending interrupts are THR interrupts.

Sleep mode is a good way to lower power consumption of the UART, but this state can be achieved only when the UART is set in modem mode. Therefore, even if the UART has no functional key role, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the `uarti_rx` line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the `UARTi.UART_SCR[4] RX_CTS_WU_EN` bit to 1. To understand how to manage the interrupt, see [Section 23.3.4.5.1.1, Wake-Up Interrupt](#).

---

**NOTE:** There must be no writing to the divisor latches, `UARTi.UART_DLL` and `UARTi.UART_DLH`, to set the baud clock, BCLK, while in sleep mode. It is advisable to disable sleep mode using the `UARTi.UART_IER[4] SLEEP_MODE` bit before writing to the `UARTi.UART_DLL` register or the `UARTi.UART_DLH` register.

---

#### **23.3.4.4.1.2 System Power Saving**

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol used at the system level to shut down the UART clocks in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the `UARTi.UART_SYSC[2] ENAWAKEUP` bit and the `UARTi.UART_WER` register).

For more information, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

#### **23.3.4.4.2 IrDA Mode Power Management (UART3 Only)**

##### **23.3.4.4.2.1 Module Power Saving**

In IrDA modes, sleep mode is enabled by setting the `UART3.MDR[3] IR_SLEEP` bit to 1.

Sleep mode is entered when all the following conditions exist:

- The serial data input line, `uart3.rx_irrx`, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the `uart3_rx_irrx` line or when data is written to the TX FIFO.

##### **23.3.4.4.2.2 System Power Saving**

System power saving for IrDA mode has the same function as that for UART mode (see [Section 23.3.4.4.1.2, System Power Saving](#)).

#### **23.3.4.4.3 CIR Mode Power Management (UART3 Only)**

##### **23.3.4.4.3.1 Module Power Saving**

Module power saving for CIR mode has the same function as that for IrDA mode (see [Section 23.3.4.4.2.1, Module Power Saving](#)).

### 23.3.4.4.3.2 System Power Saving

System power saving for CIR mode has the same function as that for UART mode (see [Section 23.3.4.4.1.2, System Power Saving](#)).

### 23.3.4.4.4 Local Power Management

[Table 23-145](#) describes power-management features available for the UART.

**NOTE:**

- For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**Table 23-145. Local Power Management features**

Feature	Registers	Description
Clock autogating	<a href="#">UART_SYSC</a> [0] AUTOIDLE	This bit allows local power optimization in the module by gating the UARTi_ICLK clock on interface activity or gating the UARTi_FCLK clock on internal activity.
Slave idle modes	<a href="#">UART_SYSC</a> [4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	<a href="#">UART_SYSC</a> [2] ENAWAKEUP	This bit enables the wake-up feature at module level.
Wake-Up sources enable	N/A	Feature not available

### 23.3.4.5 Interrupt Requests

#### 23.3.4.5.1 UART Mode Interrupt Management

UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UARTi.UART\_IIR) sets the UARTi.UART\_IIR[0] IT\_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UARTi.UART\_IIR[5:1] bit field. [Table 23-146](#) summarizes the interrupt control functions.

**Table 23-146. UART Mode Interrupts**

UART_IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	None	None	None	None
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read the <a href="#">UART_RHR</a> register. OE: Read the <a href="#">UART_LSR</a> register.
001100	2	RX time-out	Stale data in RX FIFO	Read the <a href="#">UART_RHR</a> register.
000100	2	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read the <a href="#">UART_RHR</a> register until the interrupt condition disappears.
000010	3	THR interrupt	TFE ( <a href="#">UART_THR</a> empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to the <a href="#">UART_THR</a> until the interrupt condition disappears.
000000	4	Modem status	See the <a href="#">UART_MSR</a> register.	Read the <a href="#">UART_MSR</a> register.

**Table 23-146. UART Mode Interrupts (continued)**

<b>UART_IIR[5:0]</b>	<b>Priority Level</b>	<b>Interrupt Type</b>	<b>Interrupt Source</b>	<b>Interrupt Reset Method</b>
010000	5	XOFF interrupt/special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of the <a href="#">UART_IIR</a> register, if special character interrupt.
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high).	Read the <a href="#">UART_IIR</a> register.

For the receiver-line status interrupt, the RX\_FIFO\_STS bit (UARTi.UART\_LSR[7]) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UARTi.UART\_IIR register.

#### 23.3.4.5.1.1 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the UARTi.UART\_SCR[4] RX\_CTS\_WU\_EN bit is set to 1. The UARTi.UART\_IIR register is not modified when this occurs; the UART3.UART\_SSR[1] RX\_CTS\_WU\_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, it can be cleared only by resetting the UARTi.UART\_SCR[4] RX\_CTS\_WU\_EN bit. This bit must be reenabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

#### 23.3.4.5.2 IrDA Mode Interrupt Management

##### 23.3.4.5.2.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART3.UART\_IER). The interrupt status of the device can be checked by reading the interrupt identification register (UART3.UART\_IIR).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.UART\_IER and UART3.UART\_IIR mappings, depending on the selected mode.

IrDA modes have eight possible interrupts (see [Table 23-147](#)). The interrupt line is activated when any interrupt is generated (there is no priority).

**Table 23-147. IrDA Mode Interrupts**

<b>UART_IIR Bit</b>	<b>Interrupt Type</b>	<b>Interrupt Source</b>	<b>Interrupt Reset Method</b>
0	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read the <a href="#">UART_RHR</a> register until the interrupt condition disappears.
1	THR interrupt	TFE ( <a href="#">UART_THR</a> empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to the <a href="#">UART_THR</a> until the interrupt condition disappears.
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the RHR port.	Read the <a href="#">UART_RHR</a> register.
3	RX overrun	Write to the <a href="#">UART_RHR</a> register when the RX FIFO is full.	Read <a href="#">UART_RESUME</a> register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.

**Table 23-147. IrDA Mode Interrupts (continued)**

UART_IIR Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
5	TX status	1. <a href="#">UART_THR</a> empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error. OR 2. Transmission of the last bit of the IrDA frame completed successfully.	1. Read the <a href="#">UART_RESUME</a> register. OR 2. Read the <a href="#">UART_IIR</a> register.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into the STATUS FIFO.	Read the STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame	Read the <a href="#">UART_IIR</a> register.

### 23.3.4.5.2.2 Wake-Up Interrupts

The wake-up interrupt for IrDA mode has the same function as that for UART mode (see [Section 23.3.4.5.1.1, Wake-Up Interrupt](#)).

#### CAUTION

Wake-Up interface implementation in this mode is based on the `UARTi_SIDLEACK` low-to-high transition instead of the `UARTi_SIDLEACK` state.

This does not ensure wake-up event generation as expected when configured in smart-idle mode, and the system wakes up for a short period.

### 23.3.4.5.3 CIR Mode Interrupt Management

#### 23.3.4.5.3.1 CIR Interrupts

The CIR function generates interrupts that can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (`UART3.UART_IER`). The interrupt status of the device can be checked by reading the interrupt identification register (`UART3.UART_IIR`).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different `UART3.UART_IER` and `UART3.UART_IIR` mappings, depending on the selected mode.

[Table 23-148](#) lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the `UART3.UART_IIR[5]` bit is to indicate that the last bit of infrared data was passed to the `uart3_cts_rctx` pin.

**Table 23-148. CIR Mode Interrupts**

UART_IIR Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
1	THR interrupt	TFE ( <a href="#">UART_THR</a> empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to the <a href="#">UART_THR</a> register until the interrupt condition disappears.
2	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
3	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
5	TX status	Transmission of the last bit of the frame is complete successfully.	Read the <a href="#">UART_IIR</a> register.
6	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

**Table 23-148. CIR Mode Interrupts (continued)**

UART_IIR Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
7	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

**23.3.4.5.3.2 Wake-Up Interrupts**

The wake-up interrupt for CIR mode has the same function as that for UART mode (see [Section 23.3.4.5.1.1, Wake-Up Interrupt](#)).

**23.3.4.6 FIFO Management**

The FIFO is accessed by reading and writing the UARTi.UART\_RHR and UARTi.UART\_THR registers. Parameters are controlled using the FIFO control register (UARTi.UART\_FCR) and supplementary control register (UARTi.UART\_SCR). Reading the UARTi.UART\_SSR[0] TX\_FIFO\_FULL bit at 1 means the FIFO is full.

The UARTi.UART\_TLR register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. [Figure 23-73](#) shows the FIFO management registers.

---

**NOTE:** Data in the UARTi.UART\_RHR register is not overwritten when an overflow occurs.

---

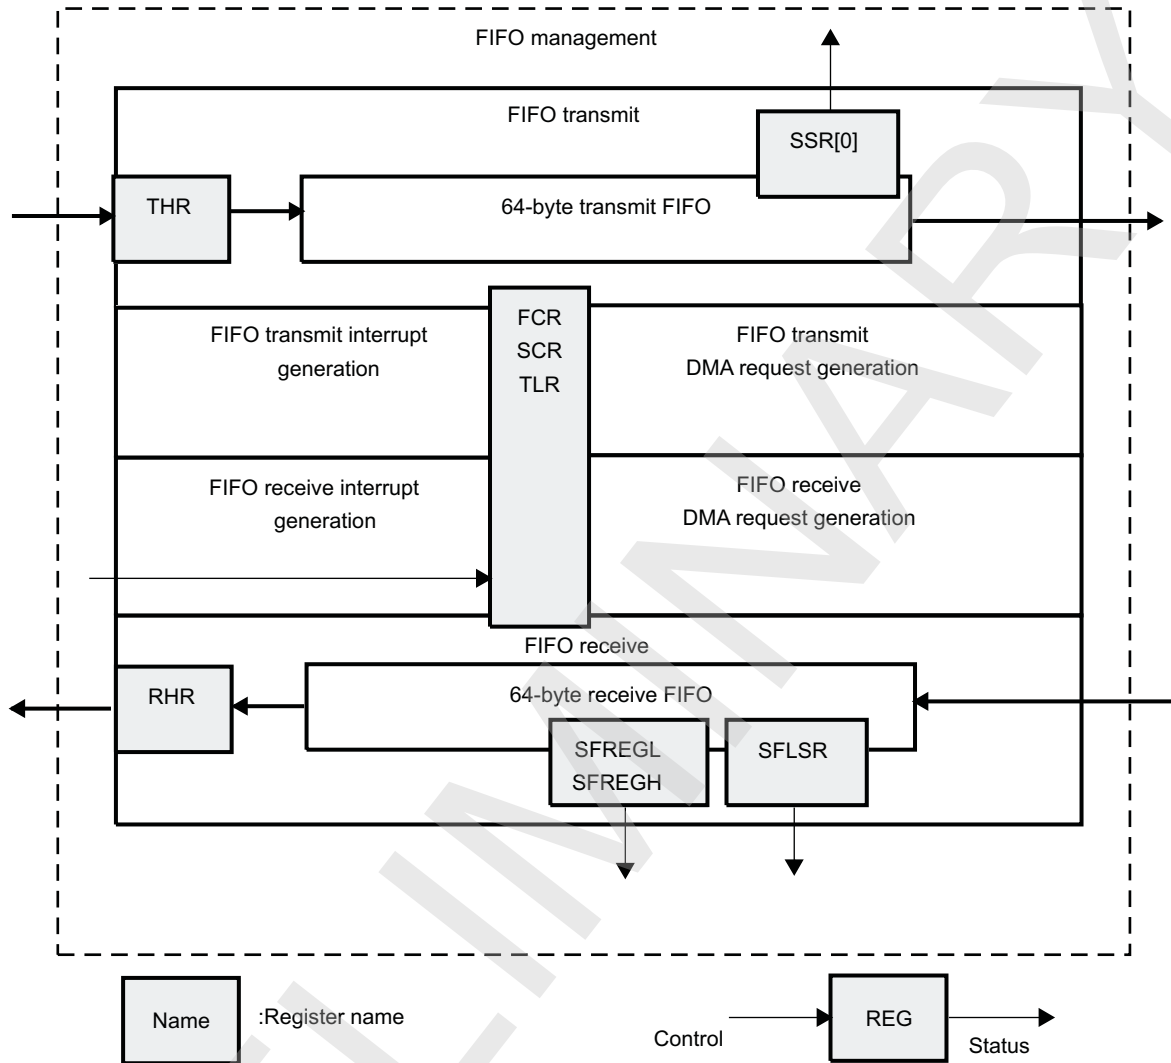

---

**NOTE:** The UARTi.UART\_SFLSR, UARTi.UART\_SFREGL, and UARTi.UART\_SFREGH status registers are used in IrDA mode only. For use, see [Section 23.3.4.8.2.3, IrDA Data Formatting](#).

---

**Figure 23-73. FIFO Management Registers**

uart-023

### 23.3.4.6.1 FIFO Trigger

#### 23.3.4.6.1.1 Transmit FIFO Trigger

Table 23-149 lists the TX FIFO trigger level settings.

**Table 23-149. TX FIFO Trigger Level Setting Summary**

UART_SCR[6]	UART_TLR[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field (8,16, 32, or 56 spaces)
0	!= 0x0	Defined by the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space) <b>Note:</b> The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of one space required). All zeros result in unpredictable behavior.

#### 23.3.4.6.1.2 Receive FIFO Trigger

Table 23-150 lists the RX FIFO trigger level settings.

**Table 23-150. RX FIFO Trigger Level Setting Summary**

UART_SCR[7]	UART_TLR[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field (8,16, 56, or 60 characters)
0	!= 0x0	Defined by the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character) <b>Note:</b> The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of one character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UARTi.UART\_TCR[7:4] RX\_FIFO\_TRIG\_START and UARTi.UART\_TCR[3:0] RX\_FIFO\_TRIG\_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4. (trigger level = 4 x [4-bit register value]).
- To ensure correct device operation, ensure that RX\_FIFO\_TRIG\_HALT > RX\_FIFO\_TRIG when auto-RTS is enabled.

$$\text{Delay} = [4 + 16 \times (1 + \text{CHAR\_LENGTH} + \text{Parity} + \text{Stop } 0.5)] \times \text{Baud\_rate} + 4 \times \text{FCLK}$$

**NOTE:** The RTS signal is deasserted after the UART module receives the data over RX\_FIFO\_TRIG\_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX\_FIFO\_TRIG\_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UARTi.UART\_TCR[7:4] RX\_FIFO\_TRIG\_START bit field or the UARTi.UART\_FCR[7:6] RX\_FIFO\_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

#### 23.3.4.6.2 FIFO Interrupt Mode

In FIFO interrupt mode (the FIFO control register UARTi.UART\_FCR[0] FIFO\_EN bit is set to 1 and

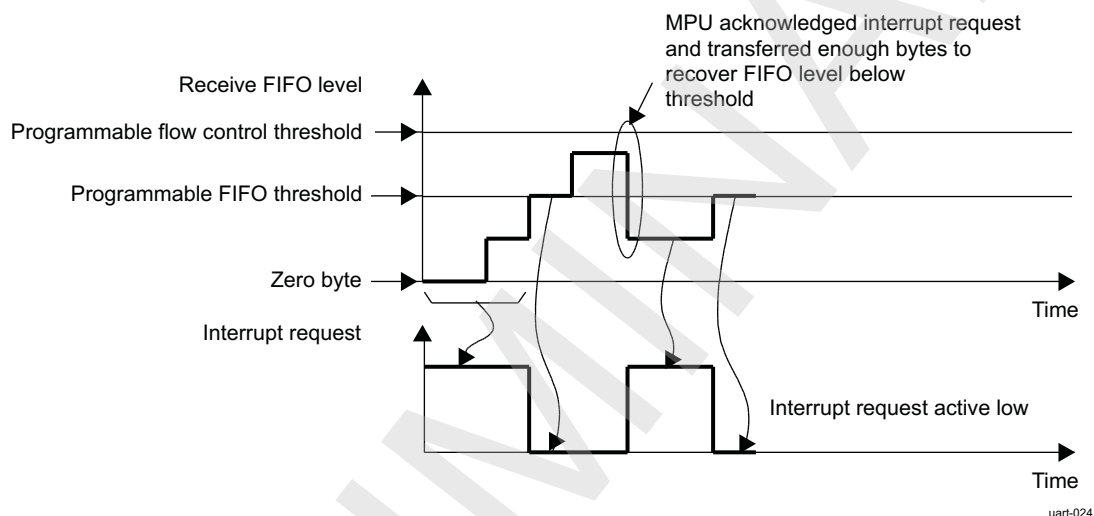

relevant interrupts are enabled by the UARTi.UART\_JER register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the receive/TX FIFO threshold (the UARTi.UART\_TLR[7:4] RX\_FIFO\_TRIG\_DMA and UARTi.UART\_TLR[3:0] TX\_FIFO\_TRIG\_DMA bit fields or the UARTi.UART\_FCR[7:6] RX\_FIFO\_TRIG and UARTi.UART\_FCR[5:4] TX\_FIFO\_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the MPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UARTi.UART\_TCR[3:0] RX\_FIFO\_TRIG\_HALT bit field) must be greater than or equal to the RX FIFO threshold.

Figure 23-74 shows the generation of the RX FIFO interrupt request.

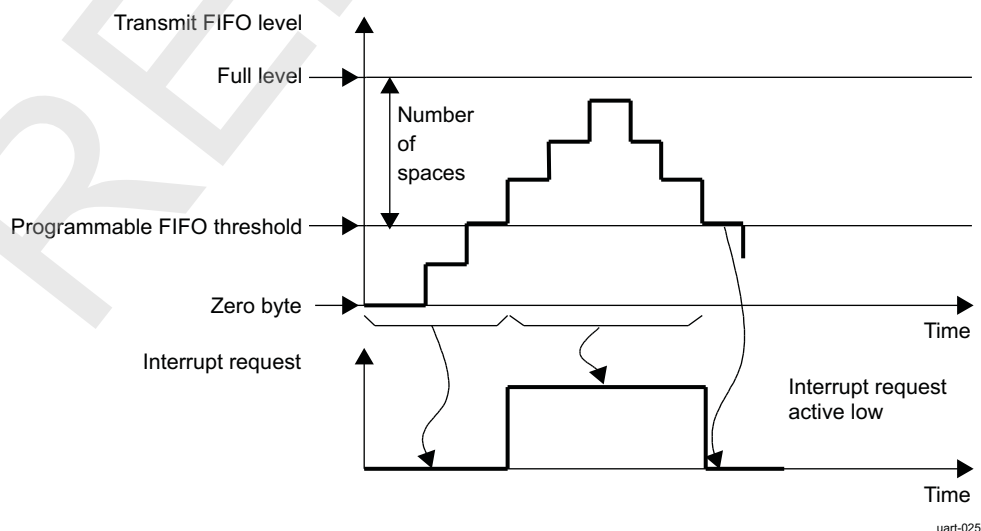

**Figure 23-74. Receive FIFO Interrupt Request Generation**

In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the MPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 23-75 shows the generation of the TX FIFO interrupt request.

**Figure 23-75. Transmit FIFO Interrupt Request Generation**

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

#### **23.3.4.6.3 FIFO Polled Mode Operation**

In FIFO polled mode (the UARTi.UART\_FCR[0] FIFO\_EN bit is set to 0 and the relevant interrupts are disabled by the UARTi.UART\_IER register), the status of the receiver and transmitter can be checked by polling the line status register (UARTi.UART\_LSR).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the MPU.

#### **23.3.4.6.4 FIFO DMA Mode Operation**

Although DMA operation includes four modes (DMA modes 0/1/2/3), the information in [Table 23-144](#) assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the following signals:

- S\_DMA\_48
- S\_DMA\_50
- S\_DMA\_52/D\_DMA\_10
- S\_DMA\_54

The following signals are not used by the module in mode 2 and mode 3:

- S\_DMA\_49
- S\_DMA\_51
- S\_DMA\_53/D\_DMA\_11
- S\_DMA\_55

These signals can be selected as follows:

- When the UARTi.UART\_SCR[0] DMA\_MODE\_CTL bit is set to 0, setting the UARTi.UART\_FCR[3] DMA\_MODE\_CTL bit to 0 enables DMA mode 0. Setting the DMA\_MODE bit to 1 enables DMA mode 1.
- When the DMA\_MODE\_CTL bit is set to 1, the UARTi.UART\_FCR[2:1] DMA\_MODE\_2 bit field determines DMA mode 0 to mode 3 based on the supplementary control register (UART\_SCR) description.

For example:

- If no DMA operation is desired, set the DMA\_MODE\_CTL bit to 1 and the DMA\_MODE\_2 bit field to 0x0. (The DMA\_MODE bit is discarded.)
- If DMA mode 1 is desired, set the DMA\_MODE\_CTL bit to 0 and the DMA\_MODE bit to 1, or set the DMA\_MODE\_CTL bit to 1 and the DMA\_MODE\_2 bit field to 01. (The DMA\_MODE bit is discarded.)

If the FIFOs are disabled (the UARTi.UART\_FCR[0] FIFO\_EN bit = 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

Depending on [UART\\_MDR3\[2\] SET\\_DMA\\_TX\\_THRESHOLD](#) the threshold can be programmed different ways:

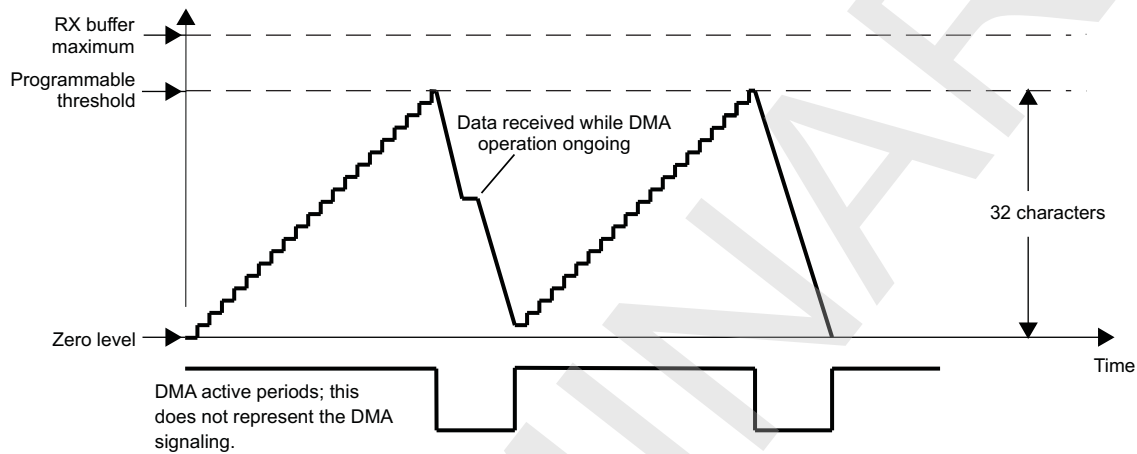

- SET\_TX\_DMA\_THRESHOLD = 1:  
The threshold value will be the value of the [UART\\_TX\\_DMA\\_THRESHOLD](#) register. If TX\_DMA\_THRESHOLD + TX trigger spaces > 64, then the default method of threshold will be used: threshold value = TX FIFO size.
- SET\_TX\_DMA\_THRESHOLD = 0:

The threshold value = TX FIFO size TX trigger space. The TX DMA line will be asserted if the TX FIFO level is lower than the threshold. It will remain asserted till TX trigger spaces number of bytes are written into the FIFO. Then the DMA line will deassert and the FIFO level will be compared with the threshold value.

#### 23.3.4.6.4.1 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 23-76 through Figure 23-79 show the supported DMA operations.

**Figure 23-76. Receive FIFO DMA Request Generation (32 Characters)**

uart-026

In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UARTi.UART\_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the system DMA (sDMA).

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the trigger level register (UARTi.UART\_TLR) is written by the sDMA. If an insufficient number of characters is written, the DMA request stays active.

Figure 23-77. Transmit FIFO DMA Request Generation (56 Spaces)

uart-027

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the `UARTi.UART_TLR` register.

The threshold can be programmed in a number of ways. Figure 23-77 shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the `UARTi.UART_FCR[5:4]` `TX_FIFO_TRIG` bit field or the `UARTi.UART_TLR[3:0]` `TX_FIFO_TRIG_DMA` bit field concatenated with the `TX_FIFO_TRIG` bit field.

The setting of 56 spaces in the UART/IrDA/CIR module must correlate with the settings of the sDMA so that the buffer does not overflow (program the DMA request size of the local host controller to equal the number of spaces in the UART/IrDA/CIR module).

Figure 23-78 shows an example with eight spaces to show the buffer level crossing the space threshold. The local host DMA controller settings must correspond to those of the UART/IrDA/CIR module.

**Figure 23-78. Transmit FIFO DMA Request Generation (8 Spaces)**

uart-028

The final example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see [Figure 23-79](#)). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UARTi.UART\_DLL and the UARTi.UART\_DLH registers.

The DMA settings must correspond to the system local host DMA controller settings to ensure correct operation of this logic.

**Figure 23-79. Transmit FIFO DMA Request Generation (1 Space)**

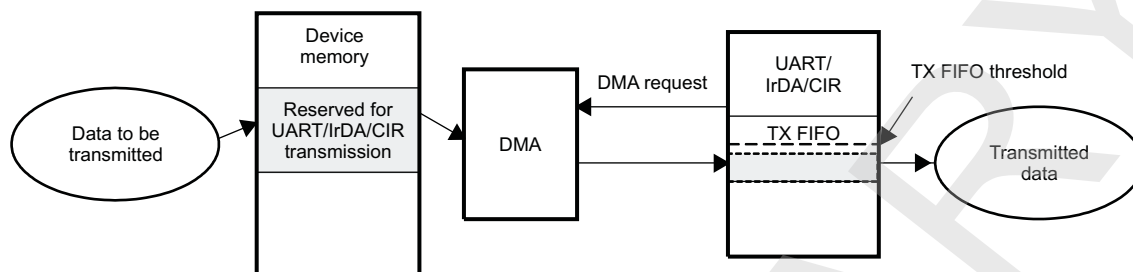

uart-029

### 23.3.4.6.4.2 DMA Transmission

Figure 23-80 shows DMA transmission.

Figure 23-80. DMA Transmission

uart-030

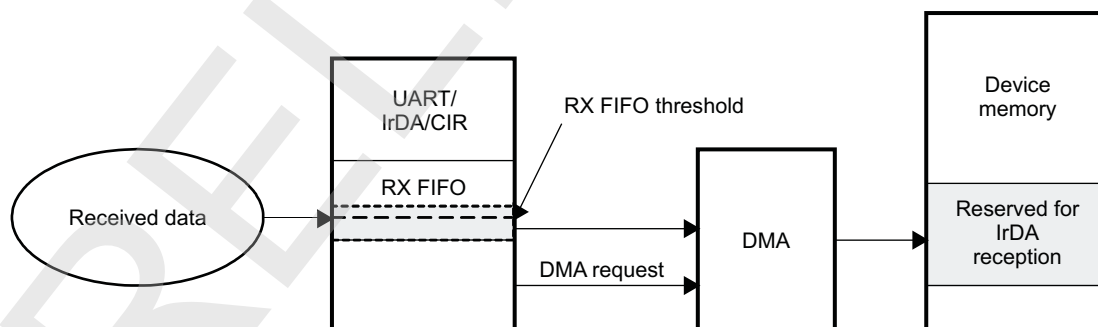

1. Data to be transmitted are put in the device memory reserved for UART/IrDA/CIR transmission by the DMA:
  - (a) Until the TX FIFO trigger level is not reached, a DMA request is generated.
  - (b) An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
2. Data in the TX FIFO are automatically transmitted.
3. The end of the transmission is signaled by the UARTi.UART\_THR empty (TX FIFO empty).

**NOTE:** In IrDA mode, the transmission does not end immediately after the TX FIFO empties, at which point there are still the last data byte, the CRC field, and the stop flag to be transmitted; thus, the end of transmission is a few milliseconds after the UARTi.UART\_THR register empties.

### 23.3.4.6.4.3 DMA Reception

Figure 23-81 shows DMA reception.

Figure 23-81. DMA Reception

uart-031

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
  - (a) At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
  - (b) An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

### 23.3.4.7 Mode Selection

#### 23.3.4.7.1 Register Access Modes

##### 23.3.4.7.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UARTi.UART\_LCR register determines the register access mode (see [Table 23-151](#)).

**Table 23-151. UART/IrDA/CIR Register Access Mode Programming (Using UART\_LCR)**

Mode	Condition
Configuration mode A	UART_LCR[7] = 0x1 and UART_LCR[7:0] != 0xBF
Configuration mode B	UART_LCR[7] = 0x1 and UART_LCR[7:0] = 0xBF
Operational mode	UART_LCR[7] = 0x0

##### 23.3.4.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR\_SPR, TCR\_TLR, and XOFF). These registers are identified in [Section 23.3.6](#), *UART/IrDA/CIR Register Manual*.

[Table 23-152](#) through [Table 23-154](#) summarize the register access submodes.

**Table 23-152. Subconfiguration Mode A Summary**

Mode	Condition
MSR_SPR	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

**Table 23-153. Subconfiguration Mode B Summary**

Mode	Condition
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1
XOFF	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)

**Table 23-154. Suboperational Mode Summary**

Mode	Condition
MSR_SPR	UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

##### 23.3.4.7.1.3 Registers Available for the Register Access Modes

[Table 23-155](#) lists the names of the register hits in each access register mode. Gray shading indicates that the register does not depend on the register access mode (available in all modes).

**Table 23-155. UART/IrDA/CIR Register Access Mode Overview**

Address Offset	Registers

(<sup>1</sup>) MSR\_SPR mode is active (see Section 23.3.4.7.1.2, Register Access Submode)

(<sup>2</sup>) TCR\_TLR mode is active (see Section 23.3.4.7.1.2, Register Access Submode)

(<sup>3</sup>) XOFF mode is active (see Section 23.3.4.7.1.2, Register Access Submode)

### 23.3.4.7.2 UART/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UARTi.UART\_MDR1[2:0] MODE\_SELECT bit field (see [Table 23-156](#)).

**Table 23-156. UART Mode Selection**

Value	Mode
0x0:	UART 16x mode
0x1:	SIR mode (UART3 only)
0x2:	UART 16x auto-baud
0x3:	UART 13x mode
0x4:	MIR mode (UART3 only)
0x5:	FIR mode (UART3 only)
0x6:	CIR mode (UART3 only)

MODE\_SELECT is effective when the module is in operational mode (see [Section 23.3.4.7.1](#), *Register Access Modes*).

#### 23.3.4.7.2.1 Registers Available for the UART Function

Only the registers listed in [Table 23-157](#) are used for the UART function.

**Table 23-157. UART Mode Register Overview<sup>(1) (2)</sup>**

Address Offset	Registers					
	Configuration Mode A		Configuration Mode B		Operational Mode

### 23.3.4.8 Protocol Formatting

#### 23.3.4.8.1 UART Mode

##### 23.3.4.8.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 23-82 shows the baud rate generator and associated controls.

**Figure 23-82. Baud Rate Generation**

uart-032

**CAUTION**

Before initializing or modifying clock parameter controls (UARTi.UART\_DLH, UARTi.UART\_DLL), MODE\_SELECT = DISABLE (UARTi.UART\_MDR1[2:0]) must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

**23.3.4.8.1.2 Choosing the Appropriate Divisor Value**

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency/(16 x baud rate)
- UART 13x mode: Divisor value = Operating frequency/(13 x baud rate)

Table 23-160 describes the UART baud rate settings.

**Table 23-160. UART Baud Rate Settings (48-MHz Clock)**

Baud Rate	Baud Multiple	DLH,DLL (Decimal)	DLH,DLL (Hex)	Actual Baud Rate	Error (%)

**23.3.4.8.1.3 UART Data Formatting**

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

**23.3.4.8.1.3.1 Frame Formatting**

When autobauding is not used, frame format attributes must be defined in the UARTi.UART\_LCR register.

Character length is specified using the UARTi.UART\_LCR[1:0] CHAR\_LENGTH bit field.

The number of stop-bits is specified using the UARTi.UART\_LCR[2] NB\_STOP bit.

The parity bit is programmed using the UARTi.UART\_LCR[5:3] PARITY\_EN, PARITY\_TYPE\_1, and PARITY\_TYPE\_2 bit fields (see Table 23-161).

**Table 23-161. UART Parity Bit Encoding**

PARITY_EN	PARITY_TYPE_1	PARITY_TYPE_2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

**23.3.4.8.1.3.2 Hardware Flow Control**

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UARTi.UART\_EFR[7:6] AUTO\_CTS\_EN and AUTO\_RTS\_EN bit fields, respectively.

With auto-CTS, uarti\_cts must be active before the module can transmit data.

Auto-RTS activates the uarti\_rts output only when there is enough room in the RX FIFO to receive data. It deactivates the uarti\_rts output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.UART\_TCR register determine the levels at which uarti\_rts is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UARTi.UART\_TCR register. uarti\_rts is active if the RX FIFO level is below the HALT trigger level in the UARTi.UART\_TCR[3:0] RX\_FIFO\_TRIG\_HALT bit field. When the RX FIFO HALT trigger level is reached, uarti\_rts is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

uarti\_rts is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UARTi.UART\_TCR[7:4] RX\_FIFO\_TRIG\_START bit field. This reassertion requests the sending device to resume transmission.

In this case, uarti\_rts is an active-low signal.

- Auto-CTS:

The transmitter circuitry checks uarti\_cts before sending the next data byte. When uarti\_cts is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, uarti\_cts must be deasserted before the middle of the last stop-bit currently sent.

The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled,

the `uarti_cts` state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

In this case, `uarti_cts` is an active-low signal.

### 23.3.4.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.UART\_EFR) and the modem control register (UARTi.UART\_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UARTi.UART\_EFR[3:0] bit field (see Table 23-162).

Two other enhanced features relate to software flow control:

- XON any function (UARTi.UART\_MCR[5]): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

---

**NOTE:** The XON-any character is written into the RX FIFO even if it is a software flow character.

---

- Special character (UARTi.UART\_EFR[5]): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.UART\_IIR[4]) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.UART\_IIR. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

**Table 23-162. UART\_EFR[0:3] Software Flow Control Options**

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2 <sup>(1)</sup>
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2 <sup>(1)</sup>

<sup>(1)</sup> In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2. XON1 is defined in the UARTi.UART\_XON1\_ADDR1[7:0] XON\_WORD1 bit field. XON2 is defined in the UARTi.UART\_XON2\_ADDR2[7:0] XON\_WORD2 bit field. XOFF1 is defined in the UARTi.UART\_XOFF1[7:0] XOFF\_WORD1 bit field. XOFF2 is defined in the UARTi.UART\_XOFF2[7:0] XOFF\_WORD2 bit field.

### 23.3.4.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. XOFF detection also sets UARTi.UART\_IIR[4] (if enabled by UARTi.UART\_IER[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, UARTi.UART\_IIR[4] is cleared and the XOFF interrupt disappears.

---

**NOTE:** When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

---

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UARTi.UART\_EFR[1:0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UARTi.UART\_EFR[1:0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

#### 23.3.4.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UARTi.UART\_TCR[3:0]. As soon as the RX FIFO reaches the trigger level programmed by UARTi.UART\_TCR[7:4], two XON1 characters are sent, so the data transfer recovers.

---

**NOTE:** If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

---

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

#### 23.3.4.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UARTi.UART\_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
  - 115.2K baud
  - 57.6K baud
  - 38.4K baud
  - 28.8K baud
  - 19.2K baud
  - 14.4K baud

- 9.6K baud
- 4.8K baud
- 2.4K baud
- 1.2K baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

---

**NOTE:** The combination of 7-bit character plus space parity is not supported.

---

Autobauding mode is selected when the UARTi.UART\_MDR1[2:0] MODE\_SELECT bit field is set to 0x2. In UART autobauding mode, UARTi.UART\_DLL, UARTi.UART\_DLH, and UARTi.UART\_LCR[5:0] bit field settings are not used; instead, UART\_UASR is updated with the configuration detected by the autobauding logic.

#### UART\_UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UARTi.UART\_LCR, UARTi.UART\_DLL, and UARTi.UART\_DLH registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UARTi.UART\_MDR1[2:0] MODE\_SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115,200 bps (10 possibilities)

#### 23.3.4.8.1.3.5 Error Detection

When the UARTi.UART\_LSR register is read, the UARTi.UART\_LSR[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UARTi.UART\_LSR register and then reading the UARTi.UART\_RHR register identifies errors in a character.

Reading the UARTi.UART\_RHR register updates the BI, FE, and PE bits (see Table 23-146 for the UART mode interrupts).

The UARTi.UART\_LSR[7] RX\_FIFO\_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

---

**NOTE:** Reading UARTi.UART\_LSR does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UARTi.UART\_RHR register.

---

Reading the UARTi.UART\_LSR register clears the OE bit if it is set (see Table 23-146 for the UART mode interrupts).

#### 23.3.4.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the MPU with UARTi.UART\_IIR[5:1] IT\_TYPE = 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the MPU must:

- Reset the RX FIFO.
- Read the UARTi.UART\_RESUME register, which clears the internal flag.

### **23.3.4.8.1.3.7 Time-Out and Break Conditions**

#### **23.3.4.8.1.3.7.1 Time-Out Counter**

An RX idle condition is detected when the receiver line (uarti\_rx) is high for a time that equals 4x the programmed word length + 12 bits. uarti\_rx is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on uarti\_rx.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on uarti\_rx or when the UARTi.UART\_RHR register is read.

#### **23.3.4.8.1.3.7.2 Break Condition**

When a break condition occurs, uarti\_tx is pulled low. A break condition is activated by setting the UARTi.UART\_LCR[6] BREAK\_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (UARTi.UART\_LSR[6] TX\_SR\_E = 1).
3. Take a guard time according to stop-bit definition.
4. Set the BREAK\_EN bit to 1.

The break condition is asserted while the BREAK\_EN bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

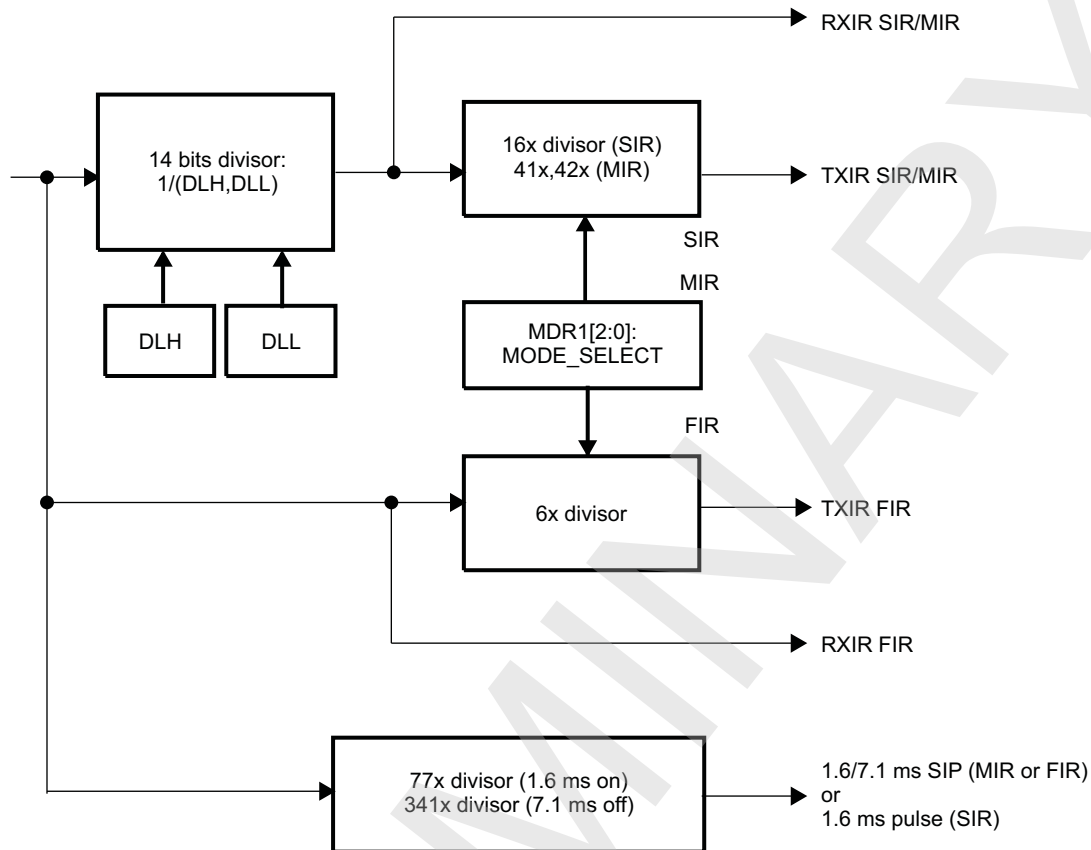

### **23.3.4.8.2 IrDA Mode (UART3 Only)**

#### **23.3.4.8.2.1 IrDA Clock Generation: Baud Generator**

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 23-83 shows the baud rate generator and associated controls.

Figure 23-83. Baud Rate Generator

uart-033

**CAUTION**

Before trying to initialize or modify clock parameter controls (UARTi.UART\_DLH, UARTi.UART\_DLL), MODE\_SELECT=DISABLE (UARTi.UART\_MDR1[2:0] must be set to 0x7.

Failure to observe this rule can result in unpredictable module behavior.

**23.3.4.8.2.2 Choosing the Appropriate Divisor Value**

Three divisor values are:

- SIR mode: Divisor value = Operating frequency/(16x baud rate)
- MIR mode: Divisor value = Operating frequency/(41x/42x baud rate)
- FIR mode: Divisor value = None

Table 23-163 lists the IrDA baud rate settings.

Table 23-163. IrDA Baud Rate Settings

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)\$	Source Jitter (%)	Pulse Duration
2.4 kbps	SIR	16x	3/16	1250	2.4 kbps	0	0	78.1 $\mu$ s
9.6 kbps	SIR	16x	3/16	312	9.6153 kbps	+0.16	0	19.5 $\mu$ s
19.2 kbps	SIR	16x	3/16	156	19.231 kbps	+0.16	0	9.75 $\mu$ s
38.4 kbps	SIR	16x	3/16	78	38.462 kbps	+0.16	0	4.87 $\mu$ s

4 Mbps	FIR	6x	4 PPM	–	4 Mbps	0	0	125 ns

<sup>(1)</sup> Average value

**NOTE:** Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

### 23.3.4.8.2.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

#### 23.3.4.8.2.3.1 IRRX Polarity Control

The UART3.UART\_MDR2[6] IRRXINVERT bit provides the flexibility to invert the uart3\_rx\_irrx pin in the UART to ensure that the protocol at the output of the transceiver has the same polarity at module level. By default, the uart3\_rx\_irrx pin is inverted because most transceivers invert the IR receive pin.

#### 23.3.4.8.2.3.2 IrDA Reception Control

The module can transmit and receive data, but when the device is transmitting, the IRRX circuitry is automatically disabled by hardware.

Operation of the uart3\_rx\_irrx input can be disabled by the UART3.UART\_ACREG[5] DIS\_IR\_RX bit.

#### 23.3.4.8.2.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives, with the UART3.UART\_XON1\_ADDR1[7:0] XON\_WORD1 and UART3.UART\_XON2\_ADDR2[7:0] XON\_WORD2 bit fields.

Setting the UART\_EFR[0] bit to 1 selects address1 checking. Setting the UART\_EFR[1] bit to 1 selects address2 checking. Setting the UART\_EFR[1:0] bit field to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for private and public addresses.

If address checking is disabled, all received frames write to the RX FIFO.

#### 23.3.4.8.2.3.4 Frame Closing

A transmission frame can be terminated in two ways:

- Frame-length method: Set the UART3.UART\_MDR1[7] FRAME\_END\_MODE bit to 0. The MPU writes the value of the frame length to the UART3.UART\_TXFLH and UART3.UART\_TXFLL registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the value of the frame length.
- Set-EOT bit method: Set the FRAME\_END\_MODE bit to 1. The MPU writes 1 to the UART3.UART\_ACREG[0] EOT bit just before it writes the last byte to the TX FIFO. When the MPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

### 23.3.4.8.2.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the MPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or an entire frame (a small frame; that is, a supervisory frame), the MPU writes 1 to the UART3.UART\_ACREG[2] SCTX\_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART3.UART\_MDR1[5] SCT bit to 1. This transmission method differs from normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

### 23.3.4.8.2.3.6 Error Detection

When the UART3.UART\_LSR register is read, the UART3.UART\_LSR[4:2] bit field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (for IrDA mode interrupts, see [Table 23-147](#)). The STATUS FIFO must be read until empty (a maximum of eight reads is required).

### 23.3.4.8.2.3.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the MPU must:

- Reset the TX FIFO.
- Read the UART3.UART\_RESUME register, which clears the internal flag.

This function can be disabled by the UART3.UART\_ACREG[4] DIS\_TX\_UNDERRUN bit, compensated by the extension of the stop-bit in transmission if the TX FIFO is empty.

### 23.3.4.8.2.3.8 Overrun During Receive

Overrun during receive for the IrDA mode has the same function as that for the UART mode (see [Section 23.3.4.8.1.3.6, Overrun During Receive](#)).

### 23.3.4.8.2.3.9 Status FIFO

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading the UART3.UART\_SFREGH[3:0] most-significant bit (MSB) and UART3.UART\_SFREGL[3:0] (LSB) bit fields obtains the frame length. The frame error status is read in the UART3.UART\_SFLSR register. Reading the UART3.UART\_SFLSR register increments the status FIFO read pointer. The status FIFO is eight entries deep and, therefore, can hold the status of eight frames.

The MPU uses the frame-length information to locate the frame boundary in the received frame data. The MPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the MPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

### 23.3.4.8.2.4 SIR Mode Data Formatting

This section provides specific instructions for SIR mode programming.

#### 23.3.4.8.2.4.1 Abort Sequence

When the transmitter prematurely closes a frame, it sends the following sequence to abort: 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UART3.UART\_ACREG[1] ABORT\_EN bit to 1.

When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

The receiver treats a frame as an aborted frame when a 0x7D character followed immediately by a 0xC1 character is received without transparency.

#### CAUTION

When the TX FIFO is not empty and the UART3.UART\_MDR1[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the abort frame is sent. Therefore, the TX FIFO must be reset before sending an abort frame.

#### 23.3.4.8.2.4.2 Pulse Shaping

SIR mode supports the 3/16 or the 1.6- $\mu$ s pulse duration methods. The UART3.UART\_ACREG[7] PULSE\_TYPE bit selects the pulse width method in the transmit mode.

#### 23.3.4.8.2.4.3 SIR Free Format Programming

The SIR FF mode is selected by setting the module in the UART mode (UART3.UART\_MDR1[2:0] MODE\_SELECT = 0x0) and the UART3.UART\_MDR2[3] UART\_PULSE bit to 1 to allow pulse shaping.

Because the bit format stays the same, some UART mode configuration registers must be set at specific values:

- UART3.UART\_LCR[1:0] CHAR\_LENGTH bit field = 0x3 (8 data bits)
- UART3.UART\_LCR[2] NB\_STOP bit = 0x0 (1 stop-bit)
- UART3.UART\_LCR[3] PARITY\_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many are not relevant (XOFF, RTS, CTS, modem status register, etc.).

#### 23.3.4.8.2.5 MIR and FIR Mode Data Formatting

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the MPU reads the line status register (UART3.UART\_LSR) to detect errors in the received frame.

When the UART3.UART\_MDR1[6] SIP\_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP\_MODE bit is set to 0, SIP transmission depends on the UART3.UART\_ACREG[3] SEND\_SIP bit.

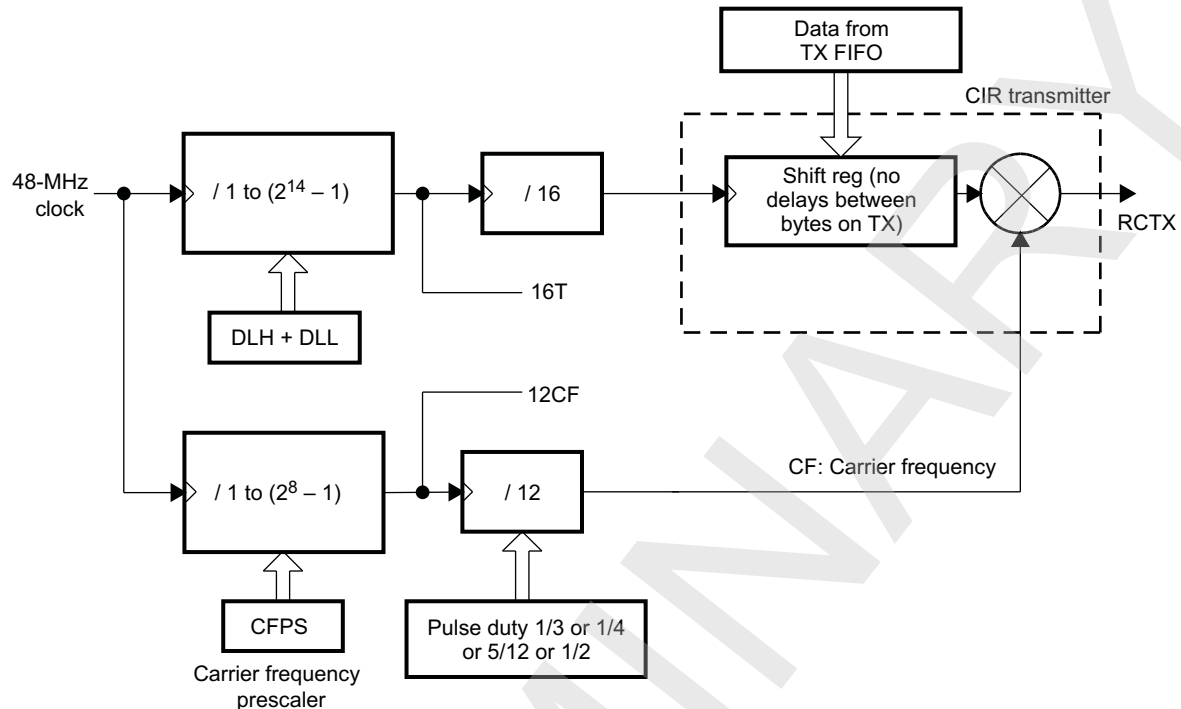

The MPU can set the SEND\_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, thus reducing the overhead required.

#### 23.3.4.8.3 CIR Mode (UART3 Only)

##### 23.3.4.8.3.1 CIR Mode Clock Generation

Depending on the encoding method (variable pulse distance/biphase), the MPU must develop a data structure that combines 1 and 0 with a  $t$  period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in [Figure 23-84](#).

Figure 23-84. CIR Mode Block Components

uart-034

Based on the requested modulation frequency, the `UART3.UART_CFPS` register must be set with the correct dividing value to provide an accurate pulse frequency:

$$\text{Dividing value} = (\text{FCLK}/12)/\text{MODfreq}$$

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the value of `UART3.UART_CFPS` must be set to 0x7 (decimal), which provides a modulation frequency of 36.04 kHz.

---

**NOTE:** The `UART3.UART_CFPS` register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

---

The duty cycle of these pulses is user-defined by the pulse duty register bits in the `UART3.UART_MDR2` register. [Table 23-164](#) shows the duty cycle.

**Table 23-164. Duty Cycle**

UART_MDR2[5:4]	Duty Cycle (High-Level)
00	1/4
01	1/3
10	5/12
11	1/2

### 23.3.4.8.3.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

#### 23.3.4.8.3.2.1 IRRX Polarity Control

The IRRX polarity control for CIR mode has the same function as that for IrDA mode (see [Section 23.3.4.8.2.3.1, IRRX Polarity Control](#)).

#### 23.3.4.8.3.2.2 CIR Transmission

In transmission, the MPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start-bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a  $t$  period
- Using an external system timer to control the delay between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
  - Controlling the start of the frame using the UART3.UART\_MDR1[5] SCT bit and the UART3.UART\_ACREG[2] SCTX\_EN bit, depending on the timer status
  - Using the UART3.UART\_IIR[5] TX\_STATUS\_IT interrupt bit to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame).

## 23.3.5 UART/IrDA/CIR Basic Programming Model

### 23.3.5.1 UART Programming Model

#### 23.3.5.1.1 Quick Start

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This 3-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

---

**NOTE:** Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see [Section 23.3.4.7.1, Register Access Modes](#).

---

#### 23.3.5.1.1.1 Software Reset

To clear the UART registers, perform the following steps:

- Step 1. Initiate a software reset:  
Set the UARTi.UART\_SYSC[1] SOFTRESET bit to 1.
- Step 2. Wait for the end of the reset operation:  
Poll the UARTi.UART\_SYSS[0] RESETDONE bit until it equals 1.

### 23.3.5.1.1.2 FIFOs and DMA Settings

To enable and configure the receive and transmit FIFOs and program the DMA mode, perform the following steps:

- Step 1. Switch to register configuration mode B to access the UARTi.UART\_EFR register:
  - (a) Save the current UARTi.UART\_LCR register value.
  - (b) Set the UARTi.UART\_LCR register value to 0x00BF.
- Step 2. Enable register submode TCR\_TLR to access the UARTi.UART\_TLR register (part 1 of 2):
  - (a) Save the UARTi.UART\_EFR[4] ENHANCED\_EN value.
  - (b) Set the UARTi.UART\_EFR[4] ENHANCED\_EN bit to 1.
- Step 3. Switch to register configuration mode A to access the UARTi.UART\_MCR register:  
Set the UARTi.UART\_LCR register value to 0x0080.
- Step 4. Enable register submode TCR\_TLR to access the UARTi.UART\_TLR register (part 2 of 2):
  - (a) Save the UARTi.UART\_MCR[6] TCR\_TLR value.
  - (b) Set the UARTi.UART\_MCR[6] TCR\_TLR bit to 1.
- Step 5. Enable the FIFO; load the new FIFO triggers (part 1 of 3) and the new DMA mode (part 1 of 2):  
Set the following bits to the desired values:
  - UARTi.UART\_FCR[7:6] RX\_FIFO\_TRIG
  - UARTi.UART\_FCR[5:4] TX\_FIFO\_TRIG
  - UARTi.UART\_FCR[3] DMA\_MODE
  - UARTi.UART\_FCR[0] FIFO\_ENABLE (0: Disable the FIFO/1; Enable the FIFO)

---

**NOTE:** The UARTi.UART\_FCR register is not readable.

---

- Step 6. Switch to register configuration mode B to access the UARTi.UART\_EFR register:  
Set the UARTi.UART\_LCR register value to 0x00BF.
- Step 7. Load the new FIFO triggers (part 2 of 3):  
Set the following bits to the desired values:
  - UARTi.UART\_TLR[7:4] RX\_FIFO\_TRIG\_DMA
  - UARTi.UART\_TLR[3:0] TX\_FIFO\_TRIG\_DMA
- Step 8. Load the new FIFO triggers (part 3 of 3) and the new DMA mode (part 2 of 2):  
Set the following bits to the desired values:
  - UARTi.UART\_SCR[7] RX\_TRIG\_GRANU1
  - UARTi.UART\_SCR[6] TX\_TRIG\_GRANU1
  - UARTi.UART\_SCR[2:1] DMA\_MODE\_2
  - UARTi.UART\_SCR[0] DMA\_MODE\_CTL
- Step 9. Restore the UARTi.UART\_EFR[4] ENHANCED\_EN value saved in Step 2a.
- Step 10. Switch to register configuration mode A to access the UARTi.UART\_MCR register:  
Set the UARTi.UART\_LCR register value to 0x0080.
- Step 11. Restore the UARTi.UART\_MCR[6] TCR\_TLR value saved in Step 4a.
- Step 12. Restore the UARTi.UART\_LCR value saved in Step 1a.

Triggers are used to generate interrupt and DMA requests. See [Section 23.3.4.6.1.1, Transmit FIFO Trigger](#), to choose the following values:

- UARTi.UART\_FCR[5:4] TX\_FIFO\_TRIG

- UARTi.UART\_TLR[3:0] TX\_FIFO\_TRIG\_DMA
- UARTi.UART\_SCR[6] TX\_TRIG\_GRANU1

Triggers are used to generate interrupt and DMA requests. See [Section 23.3.4.6.1.2, Receive FIFO Trigger](#), to choose the following values:

- UARTi.UART\_FCR[7:6] RX\_FIFO\_TRIG
- UARTi.UART\_TLR[7:4] RX\_FIFO\_TRIG\_DMA
- UARTi.UART\_SCR[7] RX\_TRIG\_GRANU1

DMA mode enables DMA requests. See [Section 23.3.4.6.4, FIFO DMA Mode Operation](#), to choose the following values:

- UARTi.UART\_FCR[3] DMA\_MODE
- UARTi.UART\_SCR[2:1] DMA\_MODE\_2
- UARTi.UART\_SCR[0] DMA\_MODE\_CTL

### 23.3.5.1.1.3 Protocol, Baud Rate, and Interrupt Settings

To program the protocol, baud rate, and interrupt settings, perform the following steps:

Step 1. Disable UART to access the UARTi.UART\_DLL and UARTi.UART\_DLH registers:

Set the UARTi.UART\_MDR1[2:0] MODE\_SELECT bit field to 0x7.

Step 2. Switch to register configuration mode B to access the UARTi.UART\_EFR register:

Set the UARTi.UART\_LCR register value to 0x00BF.

Step 3. Enable access to the UARTi.UART\_IER[7:4] bit field:

(a) Save the UARTi.UART\_EFR[4] ENHANCED\_EN value.

(b) Set the UARTi.UART\_EFR[4] ENHANCED\_EN bit to 1.

Step 4. Switch to register operational mode to access the UARTi.UART\_IER register:

Set the UARTi.UART\_LCR register value to 0x0000.

Step 5. Clear the UARTi.UART\_IER register (set the UARTi.UART\_IER[4] SLEEP\_MODE bit to 0 to change the UARTi.UART\_DLL and UARTi.UART\_DLH registers). Set the UARTi.UART\_IER register value to 0x0000.

Step 6. Switch to register configuration mode B to access the UARTi.UART\_DLL and UARTi.UART\_DLH registers:

Set the UARTi.UART\_LCR register value to 0x00BF.

Step 7. Load the new divisor value:

Set the UARTi.UART\_DLL[7:0] CLOCK\_LSB and UARTi.UART\_DLH[5:0] CLOCK\_MSB bit fields to the desired values.

Step 8. Switch to register operational mode to access the UARTi.UART\_IER register:

Set the UARTi.UART\_LCR register value to 0x0000.

Step 9. Load the new interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt):

Set the following bits to the desired values:

- UARTi.UART\_IER[7] CTS\_IT
- UARTi.UART\_IER[6] RTS\_IT
- UARTi.UART\_IER[5] XOFF\_IT
- UARTi.UART\_IER[4] SLEEP\_MODE
- UARTi.UART\_IER[3] MODEM\_STS\_IT
- UARTi.UART\_IER[2] LINE\_STS\_IT
- UARTi.UART\_IER[1] THR\_IT
- UARTi.UART\_IER[0] RHR\_IT

Step 10. Switch to register configuration mode B to access the UARTi.UART\_EFR register:

Set the UARTi.UART\_LCR register value to 0x00BF.

Step 11. Restore the UARTi.UART\_EFR[4] ENHANCED\_EN value saved in Step 3a.

Step 12. Load the new protocol formatting (parity, stop-bit, character length) and switch to register

operational mode:

Set the UARTi.UART\_LCR[7] DIV\_EN bit to 0.

Set the UARTi.UART\_LCR[6] BREAK\_EN bit to 0.

Set the following bits to the desired values:

- UARTi.UART\_LCR[5] PARITY\_TYPE\_2
- UARTi.UART\_LCR[4] PARITY\_TYPE\_1
- UARTi.UART\_LCR[3] PARITY\_EN
- UARTi.UART\_LCR[2] NB\_STOP
- UARTi.UART\_LCR[1:0] CHAR\_LENGTH

Step 13. Load the new UART mode:

Set the UARTi.UART\_MDR1[2:0] MODE\_SELECT bit field to the desired value.

See [Section 23.3.4.8.1.2, Choosing the Appropriate Divisor Value](#), to choose the following values:

- UARTi.UART\_DLL[7:0] CLOCK\_LSB
- UARTi.UART\_DLH[5:0] CLOCK\_MSB
- UARTi.UART\_MDR1[2:0] MODE\_SELECT

See [Section 23.3.4.8.1.3.1, Frame Formatting](#), to choose the following values:

- UARTi.UART\_LCR[5] PARITY\_TYPE\_2
- UARTi.UART\_LCR[4] PARITY\_TYPE\_1
- UARTi.UART\_LCR[3] PARITY\_EN
- UARTi.UART\_LCR[2] NB\_STOP
- UARTi.UART\_LCR[1:0] CHAR\_LENGTH

### 23.3.5.1.2 Hardware and Software Flow Control Configuration

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

---

**NOTE:** Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see [Section 23.3.4.7.1, Register Access Modes](#).

---

#### 23.3.5.1.2.1 Hardware Flow Control Configuration

To enable and configure hardware flow control, perform the following steps:

Step 1. Switch to register configuration mode A to access the UARTi.UART\_MCR register:

- (a) Save the current UARTi.UART\_LCR register value.
- (b) Set the UARTi.UART\_LCR register value to 0x0080.

Step 2. Enable register submode TCR\_TLR to access the UARTi.UART\_TCR register (part 1 of 2):

- (a) Save the UARTi.UART\_MCR[6] TCR\_TLR value.
- (b) Set the UARTi.UART\_MCR[6] TCR\_TLR bit to 1.

Step 3. Switch to register configuration mode B to access the UARTi.UART\_EFR register:

Set the UARTi.UART\_LCR register value to 0x00BF.

Step 4. Enable register submode TCR\_TLR to access the UARTi.UART\_TCR register (part 2 of 2):

- (a) Save the UARTi.UART\_EFR[4] ENHANCED\_EN value.
- (b) Set the UARTi.UART\_EFR[4] ENHANCED\_EN bit to 1.

Step 5. Load the new start and halt trigger values for hardware flow control:

Set the following bits to the desired values:

- UARTi.UART\_TCR[7:4] AUTO\_RTS\_START

- UARTi.UART\_TCR[3:0] AUTO\_RTS\_HALT
- Step 6. Enable or disable receive and transmit hardware flow control mode and restore the UARTi.UART\_EFR[4] ENHANCED\_EN value saved in Step 4a.

Set the following bits to the desired values:

- UARTi.UART\_EFR[7] AUTO\_CTS\_EN (0: Disable; 1: Enable)
- UARTi.UART\_EFR[6] AUTO\_RTS\_EN (0: Disable; 1: Enable)

Restore the UARTi.UART\_EFR[4] ENHANCED\_EN bit to the saved value.

Step 7. Switch to register configuration mode A to access the UARTi.UART\_MCR register:

Set the UARTi.UART\_LCR register value to 0x0080.

Step 8. Restore the UARTi.UART\_MCR[6] TCR\_TLR value saved in Step 2a.

Step 9. Restore the UARTi.UART\_LCR value saved in Step 1a.

See [Section 23.3.4.8.1.3.2, Hardware Flow Control](#), to choose the following values:

- UARTi.UART\_EFR[7] AUTO\_CTS\_EN
- UARTi.UART\_EFR[6] AUTO\_RTS\_EN
- UARTi.UART\_TCR[7:4] AUTO\_RTS\_START
- UARTi.UART\_TCR[3:0] AUTO\_RTS\_HALT

### 23.3.5.1.2.2 Software Flow Control Configuration

To enable and configure software flow control, perform the following steps:

Step 1. Switch to register configuration mode B to access the UARTi.UART\_EFR register.

- (a) Save the current UARTi.UART\_LCR register value.
- (b) Set the UARTi.UART\_LCR register value to 0x00BF.

Step 2. Enable register submode XOFF to access the UARTi.UART\_XOFF1 and UARTi.UART\_XOFF2 registers:

- (a) Save the UARTi.UART\_EFR[4] ENHANCED\_EN value.
- (b) Set the UARTi.UART\_EFR[4] ENHANCED\_EN bit to 0.

Step 3. Load the new software flow control characters:

Set the following bits to the desired values:

- UARTi.UART\_XON1\_ADDR1[7:0] XON\_WORD1
- UARTi.UART\_XON2\_ADDR2[7:0] XON\_WORD2
- UARTi.UART\_XOFF1[7:0] XOFF\_WORD1
- UARTi.UART\_XOFF2[7:0] XOFF\_WORD2

Step 4. Enable access to the UARTi.UART\_MCR[7:5] bit field and enable register submode TCR\_TLR to access the UARTi.UART\_TCR register (part 1 of 2):

Set the UARTi.UART\_EFR[4] ENHANCED\_EN bit to 1.

Step 5. Switch to register configuration mode A to access the UARTi.UART\_MCR register:

Set the UARTi.UART\_LCR register value to 0x0080.

Step 6. Enable register submode TCR\_TLR to access the UARTi.UART\_TCR register (part 2 of 2) and enable or disable XON any function:

- (a) Save the UARTi.UART\_MCR[6] TCR\_TLR value.
- (b) Set the UARTi.UART\_MCR[6] TCR\_TLR bit to 1.  
Set the UARTi.UART\_MCR[5] XON\_EN bit to the desired value (0: Disable; 1: Enable).

Step 7. Switch to register configuration mode B to access the UARTi.UART\_EFR register:

Set the UARTi.UART\_LCR register value to 0x00BF.

Step 8. Load the new start and halt trigger values for software flow control:

Set the following bits to the desired values:

- UARTi.UART\_TCR[7:4] AUTO\_RTS\_START
- UARTi.UART\_TCR[3:0] AUTO\_RTS\_HALT

Step 9. Enable or disable special character function and load the new software flow control mode and

restore the UARTi.UART\_EFR[4] ENHANCED\_EN value saved in Step 2a:

Set the following bits to the desired values:

- UARTi.UART\_EFR[5] SPEC\_CHAR (0: Disable; 1: Enable)
- UARTi.UART\_EFR[3:0] SW\_FLOW\_CONTROL

Restore the UARTi.UART\_EFR[4] ENHANCED\_EN bit to the saved value.

Step 10. Switch to register configuration mode A to access the UARTi.UART\_MCR register:

Set the UARTi.UART\_LCR register value to 0x0080.

Step 11. Restore the UARTi.UART\_MCR[6] TCR\_TLR bit value saved in Step 6a.

Step 12. Restore the UARTi.UART\_LCR value saved in Step 1a.

See [Section 23.3.4.8.1.3.3, Software Flow Control](#), to choose the following values:

- UARTi.UART\_EFR[5] SPEC\_CHAR
- UARTi.UART\_EFR[3:0] SW\_FLOW\_CONTROL
- UARTi.UART\_TCR[7:4] AUTO\_RTS\_START
- UARTi.UART\_TCR[3:0] AUTO\_RTS\_HALT
- UARTi.UART\_XON1\_ADDR1[7:0] XON\_WORD1
- UARTi.UART\_XON2\_ADDR2[7:0] XON\_WORD2
- UARTi.UART\_XOFF1[7:0] XOFF\_WORD1
- UARTi.UART\_XOFF2[7:0] XOFF\_WORD2

### 23.3.5.2 IrDA Programming Model (UART3 Only)

#### 23.3.5.2.1 SIR Mode

##### 23.3.5.2.1.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with parity forced to 1, baud rate = 112.5KB, FIFOs disabled, 2 stop-bits, and 8-bit word length:

1. Disable the UART before accessing the UARTi.[UART\\_DLL](#) and UARTi.[UART\\_DLH](#) registers:  
Set the UARTi.[UART\\_MDR1](#)[2:0] MODE\_SELECT bit field to 0x7.
2. Grant access to the [UART\\_DLL](#) and [UART\\_DLH](#) registers (the [UART\\_LCR](#)[7] DIV\_EN bit = 1):  
UART3.[UART\\_LCR](#) = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.[UART\\_LCR](#) register in IrDA mode.)
3. Load the new baud rate (115.2 kbps):  
UART3.[UART\\_DLL](#) = 0x1A  
UART3.[UART\\_DLH](#) = 0x00
4. Set SIR mode:  
UART3.[UART\\_MDR1](#)[2:0] MODE\_SELECT = 0x1
5. Disable access to the [UART\\_DLL](#) and [UART\\_DLH](#) registers and switch to register operational mode:  
UART3.[UART\\_LCR](#) = 0x00.
6. Optional: Enable the RHR interrupt:  
UART3.[UART\\_IER](#)[0] RHR\_IT = 0x1

##### 23.3.5.2.1.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 6-byte frame with no parity, baud rate = 112.5 kbps, FIFOs disabled, 3/16 encoding, 2 stop-bits, and 7-bit word length:

1. Disable the UART before accessing the UARTi.[UART\\_DLL](#) and UARTi.[UART\\_DLH](#) registers:  
Set the [UART\\_MDR1](#)[2:0] MODE\_SELECT bit field to 0x7.
2. Grant access to the [UART\\_EFR](#) register:  
UART3.[UART\\_LCR](#) = 0xBF
3. Enable the enhanced features (the [UART\\_EFR](#)[4] ENHANCED\_EN bit = 1):  
Set the UART3.[UART\\_EFR](#) register value to 0x10.
4. Grant access to the [UART\\_DLL](#) and [UART\\_DLH](#) registers (the [UART\\_LCR](#)[7] DIV\_EN bit = 1):  
UART3.[UART\\_LCR](#) = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.[UART\\_LCR](#) register in IrDA mode.)
5. Load the new baud rate (115.2 kbps):  
UART3.[UART\\_DLL](#) = 0x1A  
UART3.[UART\\_DLH](#) = 0x00
6. Set SIR mode (the [UART\\_MDR1](#)[2:0] MODE\_SELECT bit field = 0x1):  
UART3.[UART\\_MDR1](#) = 0x01
7. Disable access to the [UART\\_DLL](#) and [UART\\_DLH](#) registers and switch to register operational mode:  
UART3.[UART\\_LCR](#) = 0x00.
8. Force DTR output to active:  
UART3.[UART\\_MCR](#)[0] DTR = 1
9. Optional: Enable the THR interrupt:  
UART3.[UART\\_IER](#)[1] THR\_IT = 1
10. Set transmit frame length to 6 bytes:  
UART3.[UART\\_TXFLR](#) = 0x06
11. Set 7 starts of frame transmission:  
UART3.[UART\\_EBLR](#) = 0x08
12. Optional: Set SIR pulse width to be 1.6 us:  
UART3.[UART\\_ACREG](#)[7] PULSE\_TYPE = 1
13. Load [UART\\_THR](#) with the desired data to be transmitted.

### 23.3.5.2.2 MIR Mode

#### 23.3.5.2.2.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with no parity, baud rate = 1.152 mpbs, and FIFOs disabled.

1. Disable the UART before accessing the UARTi.UART\_DLL and UARTi.UART\_DLH registers:  
Set the UARTi.UART\_MDR1[2:0] MODE\_SELECT bit field to 0x7.
2. Grant access to the UART\_DLL and UART\_DLH registers (UART\_LCR[7] DIV\_EN bit = 1):  
UART3.UART\_LCR = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.UART\_LCR register in IrDA mode.)
3. Load the new baud rate (1.152 mpbs):  
UART3.UART\_DLL = 0x01  
UART3.UART\_DLH = 0x00
4. Set MIR mode:  
UART3.UART\_MDR1[2:0] MODE\_SELECT = 0x4
5. Disable access to the UART\_DLL and UART\_DLH registers and switch to register operational mode:  
UART3.UART\_LCR = 0x00
6. Force DTR output to active (UART\_MCR[0] DTR = 1):  
Force RTS output to active (UART\_MCR[1] RTS = 1).  
UART3.UART\_MCR = 0x3
7. Optional: Enable the RHR interrupt:  
UART3.UART\_IER[0] RHR\_IT = 1

#### 23.3.5.2.2.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 60-byte frame with no parity, baud rate = 1.152 Mbps, and FIFOs disabled:

1. Disable the UART before accessing the UARTi.UART\_DLL and UARTi.UART\_DLH registers:  
Set the UARTi.UART\_MDR1[2:0] MODE\_SELECT bit field to 0x7.
2. Grant access to the UART\_DLL and UART\_DLH registers (UART\_LCR[7] DIV\_EN bit = 1):  
UART3.UART\_LCR = 0x80 (**Note:** Data format is unaffected by the use and settings of the UART3.UART\_LCR register in IrDA mode.)
3. Load the new baud rate (1.152 mpbs):  
UART3.UART\_DLL = 0x01  
UART3.UART\_DLH = 0x00
4. Set MIR mode:  
UART3.UART\_MDR1[2:0] MODE\_SELECT = 0x4.
5. Disable access to the UART\_DLL and UART\_DLH registers and switch to register operational mode:  
UART3.UART\_LCR = 0x00
6. Force DTR output to active:  
UART3.UART\_MCR[0] DTR = 1
7. Optional: Enable the THR interrupt:  
UART3.UART\_IER[1] THR\_IT = 1
8. Set the frame length to 60 bytes:  
UART3.UART\_TXFLL = 0x3C
9. Optional: Transmit 8 additional starts of frame (MIR mode requires two starts):  
UART3.UART\_EBLR = 0x08
10. SIP is sent at the end of transmission:  
UART3.UART\_ACREG[3] = 1
11. Load the UART\_THR register with the data to be transmitted.

### 23.3.5.2.3 FIR Mode

#### 23.3.5.2.3.1 Receive

The following programming model explains how to program the module to receive IrDA frame with no parity, baud rate = 4M bits/s, FIFOs enable, 8-bit word length.

1. Disable the UART before accessing the UART3.UART\_DLL and UART3.UART\_DLH registers:  
Set the UART3.UART\_MDR1[2:0] MODE\_SELECT bit field to 0x7.
2. Grant access to the UART\_DLL and UART\_DLH registers (UART\_LCR[7] DIV\_EN bit = 1):  
UART3.UART\_LCR = 0x80 (**Note:** Data format is unaffected by the use and settings of the UART3.UART\_LCR register in IrDA mode.)
3. FIFO clear and enable:  
UART3.UART\_FCR = 0x7 (Tx/Rx FIFO trigger : UART\_FCR[7:6] and UART\_FCR[5:4])  
UART3.UART\_LCR[7]=0
4. Set FIR mode:  
UART3.UART\_MDR1[2:0] MODE\_SELECT = 0x5
5. Set frame length:  
UART3.UART\_RXFLL = 0xA (Data + CRC + STOP)
6. Disable access to UART3.UART\_DLL and UART3.UART\_DLH and switch to register operational mode:  
UART3.UART\_LCR[7] DIV\_EN = 0x0
7. Optional: Enable the RHR interrupt:  
UART3.UART\_IER[0] RHR\_IT = 1

#### 23.3.5.2.3.2 Transmit

The following programming model explains how to program the module to transmit IrDA 4 bytes frame with no parity, baud rate = 4 Mbps, FIFOs enable, 8-bit word length.

1. Disable the UART before accessing the UART3.UART\_DLL and UART3.UART\_DLH registers:  
Set the UART3.UART\_MDR1[2:0] MODE\_SELECT bit field to 0x7.
2. Grant access to EFR\_REG:  
UART3.UART\_LCR = 0xBF
3. Enable the enhanced features (EFR\_REG[4] ENAHNCED\_EN = 0x1):  
UART3.UART\_EFR = 0x10
4. FIFO clear and enable:  
UART3.UART\_FCR = 0x7 (Tx/Rx FIFO trigger: UART\_FCR[7:6] and UART\_FCR[5:4]).  
UART3.UART\_LCR[7] = 0
5. Set FIR mode and enable auto-SIP mode:  
UART3.UART\_MDR1 = 0x45
6. Set Frame Length:  
UART3.UART\_TXFLL = 0x4  
UART3.UART\_TXFLH = 0x0  
UART3.UART\_RXFLL = 0xA (Data + CRC + STOP)  
UART3.UART\_RXFLH = 0x0
7. Force DTR output to active:  
UART3.UART\_MCR[0] DTR = 0x1
8. Optional: Enable THR interrupt:  
UART3.UART\_IER[1] THR\_IT = 0x1
9. Optional: Transmit 8 additional starts of frame (MIR mode requires two starts):  
UART3.UART\_EBLR = 0x08
10. SIP is sent at the end of transmission:  
UART3.UART\_ACREG[3] = 1
11. Load the UART\_THR register with the data to be transmitted.

## 23.3.6 UART/IrDA/CIR Register Manual

### 23.3.6.1 UART/IrDA/CIR Instance Summary

Table 23-165 shows the base address and address space for the UART/IrDA/CIR module instances.

**Table 23-165. UART/IrDA/CIR Instance Summary**

Module Name	Base Address	Size
UART1 <sup>(1)</sup>	0x4806 A000	1KB
UART2 <sup>(1)</sup>	0x4806 C000	1KB
UART3 <sup>(2)</sup>	0x4802 0000	1KB
UART4 <sup>(1)</sup>	0x4806 E000	1KB

<sup>(1)</sup> UART mode only

<sup>(2)</sup> UART, IrDA, or CIR mode

### 23.3.6.2 UART/IrDA/CIR Registers

**23.3.6.2.2 UART/IrDA/CIR Registers****Table 23-168. UART\_THR**

<b>Address Offset</b>	0x0000 0000																																																																
<b>Physical Address</b>	See <a href="#">Table 23-166</a> to <a href="#">Table 23-167</a> .																																																																
<b>Description</b>	The transmitter section consists of the transmit holding register (THR) and the transmit shift register. The transmit holding register is a 64-byte FIFO. The local host (LH) writes data to the THR. The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location 0 of the FIFO stores the data.

<b>Physical Address</b>	See <a href="#">Table 23-166</a> to <a href="#">Table 23-167</a> .	<b>Instance</b> UART																																																												
<b>Description</b>	The receiver section consists of the receiver holding register (RHR) and the receiver shift register. The RHR is a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR. If the FIFO is disabled, location 0 of the FIFO stores the single data character. <b>Note:</b> If an overflow occurs, the data in the RHR is not overwritten.

<b>Address Offset</b>	0x0000 0018	
<b>Physical Address</b>	See <a href="#">Table 23-166</a> to <a href="#">Table 23-167</a> .	<b>Instance</b> UART
<b>Description</b>	Transmission control register This register stores the RX FIFO threshold levels to start/stop transmission during hardware/software flow control. Notes: Trigger levels from 0 - 60 bytes are available with a granularity of four. (Trigger level = 4 x [4-bit register value]) The programmer must ensure that <code>UART_TCR[3:0] &gt; UART_TCR[7:4]</code> when auto-RTS or software flow control is enabled to avoid a mis-operation of the device. In FIFO interrupt mode with flow control, the programmer must ensure that the trigger level to halt transmission is greater than or equal to the RX FIFO trigger level ( <code>UART_TLR[7:4]</code> or <code>UART_FCR[7:6]</code> ); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist because a DMA request is sent each time a byte is received.	
<b>Type</b>	RW

<b>Address Offset</b>	0x0000 0020	
<b>Physical Address</b>	See Table 23-166 to Table 23-167.	<b>Instance</b> UART
<b>Description</b>	<p>Mode definition register 1</p> <p>The mode of operation can be programmed by writing to MDR1[2:0] and therefore the MDR1 must be programmed on startup after configuration of the configuration registers (UART_DLL, UART_DLH, and UART_LCR). The value of MDR1[2:0] must not be changed again during normal operation. <b>Note:</b> If the module is disabled by setting the MODE_SELECT field to 111, interrupt requests can still be generated unless disabled through the interrupt enable register (IER). In this case, UART mode interrupts are visible. Reading the interrupt identification register (IIR) shows UART mode interrupt flags.</p>	
<b>Type</b>	RW

<b>Address Offset</b>	0x0000 0024	<b>Instance</b>	UART
<b>Physical Address</b>	See Table 23-166 to Table 23-167.		
<b>Description</b>	<p>Mode definition register 2</p> <p>IR-IrDA and IR-CIR modes only. <b>UART_MDR2</b>[0] describes the status of the interrupt in <b>UART_IIR</b>[5]. The IRTX_UNDERRUN bit should be read after an <b>UART_IIR</b>[5] TX_STATUS_IT interrupt. The bits [2:1] of this register set the trigger level for the frame status FIFO (8 entries) and must be programmed before the mode is programmed in <b>UART_MDR1</b>[2:0].</p> <p><b>Note:</b> The <b>UART_MDR2</b>[6] gives the flexibility to invert the RX pin in the UART to ensure that the protocol at the input of the transceiver module has the same polarity at module level. By default, the RX pin is inverted because most transceivers invert the IR receive pin.</p>		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																SET_TXIR_ALT	IRRXINVERT	CIR_PULSE_MODE	UART_PULSE	STS_FIFO_TRIG	IRTX_UNDERRUN										

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0. Write has no effect.	RW	0x000000
7	SET_TXIR_ALT	Provide alternate function for MDR1[4] (SET_TXIR). 0x0: Normal mode 0x1: Alternate mode for SET_TXIR	R	0

Bits	Field Name	Description	Type	Reset
6	IRRXINVERT	IR mode only (IRDA and CIR). Invert RX pin in the module before the voting or sampling system logic of the infrared block. This does not affect the RX path in UART modem modes.  0x0: Inversion is performed. 0x1: No inversion is performed.	RW	0
5:4	CIR_PULSE_MODE	CIR pulse modulation definition. Defines high level of the pulse width associated with a digit: 0x0: Pulse width of 3 from 12 cycles 0x1: Pulse width of 4 from 12 cycles 0x2: Pulse width of 5 from 12 cycles 0x3: Pulse width of 6 from 12 cycles	RW	0x0
3	UART_PULSE	UART mode only. Allows pulse shaping in UART mode. 0x0: Normal UART mode 0x1: UART mode with a pulse shaping	RW	0
2:1	STS_FIFO_TRIG	IR-IRDA mode only. Frame status FIFO threshold select: 0x0: 1 entry 0x1: 4 entries 0x2: 7 entries 0x3: 8 entries	RW	0x0
0	IRTX_UNDERRUN	IRDA transmission status interrupt. When the <a href="#">UART_IIR[5]</a> interrupt occurs, the meaning of the interrupt is :  Read 0x0: The last bit of the frame transmitted successfully without error.  Read 0x1: An underrun occurred. The last bit of the frame was transmitted but with an underrun error. The bit is reset to 0 when the <a href="#">UART_RESUME</a> register is read.	R	0

<b>Description</b>	Transmit frame length register high IrDA modes only. The <code>UART_TXFLH</code> and <code>UART_TXFLH</code> registers hold the 13-bit transmit frame length (expressed in bytes). <code>UART_TXFLH</code> holds the LSBs and <code>UART_TXFLH</code> holds the MSBs. The frame length value is used if the frame length method of frame closing is used.		
<b>Type</b>	W

<b>Description</b>	<p>UART autobauding status register</p> <p>UART autobauding mode only. This status register returns the speed, the number of bits by characters, and the type of the parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition.</p> <p><b>Note:</b> When the UART is in autobauding mode, this register, instead of the LCR, DLL, and DLH registers, is used to set up transmission according to the characteristics of the previous reception. To reset the autobauding hardware (to start a new AT detection), set MDR1[2:0] to 111 (reset value), then set MDR1[2:1] to 010 (UART in autobaud mode). To set the UART to standard mode (no autobaud), set MDR1[2:1] to 000.</p>

<b>Description</b>	Auxiliary control register. IR-IrDA and IR-CIR modes only		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
RESERVED																											PULSE_TYPE	SD_MOD	DIS_IR_RX	DIS_TX_UNDERRUN	SEND_SIP	SCTX_EN	ABORT_EN	EOT_EN

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0. Write has no effect.	RW	0x000000
7	PULSE_TYPE	SIR pulse width select 0x0: 3/16 of baud-rate pulse width 0x1: 1.6 us	RW	0
6	SD_MOD	Primary output used to configure transceivers. Connected to the SD/MODE input pin of IrDA transceivers. 0x0: SD pin is set to high. 0x1: SD pin is set to low.	RW	0
5	DIS_IR_RX	0x0: Normal operation (RX input automatically disabled during transmit but enabled outside of transmit operation) 0x1: Disables RX input (permanent state - independent of transmit)	RW	0
4	DIS_TX_UNDERRUN	It is recommended to disable TX FIFO underrun capability by masking corresponding underrun interrupt. When disabling underrun by setting ACREG[4] = 1, garbage data is sent over TX line. 0x0: Long stop-bits cannot be transmitted; TX underrun is enabled. 0x1: Long stop-bits can be transmitted; TX underrun is disabled.	RW	0

Bits	Field Name	Description	Type	Reset
3	SEND_SIP	MIR/FIR modes only. Send serial infrared interaction pulse (SIP). If this bit is set during an MIR/FIR transmission, the SIP is sent at the end of it. This bit is cleared automatically at the end of the SIP transmission. 0x0: No action 0x1: Send SIP pulse.	RW	0
2	SCTX_EN	Store and controlled TX start. When MDR1[5] = 1 and the LH writes 1 to this bit, the TX state-machine starts frame transmission. This bit is self-clearing.	RW	0
1	ABORT_EN	Frame abort. The LH can intentionally abort transmission of a frame by writing 1 to this bit. Neither the end flag nor the CRC bits are appended to the frame. If TX FIFO is not empty and MDR1[5] = 1, UART IrDA starts a new transfer with data of the previous frame when the abort frame is sent. Therefore, TX FIFO must be reset before sending an abort frame.	RW	0
0	EOT_EN	EOT (end of transmission) bit. The LH writes 1 to this bit just before it writes the last byte to the TX FIFO in set-EOT bit frame closing method. This bit is cleared automatically when the LH writes to the THR (TX FIFO).	RW	0

<b>Description</b>	<p>BOF length register</p> <p>IR-IrDA and IR-CIR modes only. In IR-IrDA SIR operation, this register specifies the number of BOF + xBOFs to transmit. Value set into this register must account for the BOF character; therefore, to send only one BOF with no XBOF, this register must be set to 1. To send one BOF with N XBOF, this register must be set to N + 1. The value 0 sends 1 BOF plus 255 XBOF. In IR-IrDA MIR mode, this register specifies the number of additional start flags (MIR protocol mandates a minimum of 2 start flags). In IR-CIR mode, this register specifies the number of consecutive 0s to be received before generating the RX_STOP interrupt (<a href="#">UART_IIR[2]</a>). All received 0s are stored in the RX FIFO. When the register is set to 0, this feature is deactivated and always in reception state, which can be disabled by setting the ACREG[5] to 1.</p> <p><b>Note:</b> If the RX_STOP interrupt occurs before a byte boundary, the remaining bits of the last byte are filled with 0s and passed into the RX FIFO.</p>

<b>Description</b>	System configuration register The auto idle bit controls a power-saving technique to reduce the logic power consumption of the open-core protocol (OCP) interface. When the feature is enabled, the clock is gated off until an OCP command for this device is detected. When the software reset bit is set high, it causes a full device reset.

<b>Description</b>	Wake-Up enable register  The UART wake-up enable register is used to mask and unmask a UART event that would subsequently notify the system. an event is any activity in the logic that could cause an interrupt and/or an activity that would require the system to wake up. Even if the wakeup is disabled for certain events, if these events are also an interrupt to the UART, the UART registers the interrupt.

<b>Description</b>	Carrier frequency prescaler  Because the consumer IR works at modulation rates of 30 - 56.8 kHz, the 48-MHz clock must be prescaled before the clock can drive the IR logic. This register sets the divisor rate to give a range to accommodate the remote-control requirements in baud multiples of 12x. The value of the CFPS at reset is 0105 decimal, which equals 38.1 KHz output from starting conditions. The 48-MHz carrier is prescaled by the CFPS, which is then divided by the 12x baud multiple.

## 23.4 Multichannel Serial Port Interface (MCSPi)

This section describes the four multichannel serial port interface (MCSPi) modules for the device.

### 23.4.1 MCSPi Overview

The multichannel serial port interface (MCSPi) is a master/slave synchronous serial bus. The MCSPi has four separate modules (SPI1, SPI2, SPI3, and SPI4) in the device (see [Figure 23-85](#)). The MCSPi modules differ as follows: SPI1 supports up to four peripherals, SPI2 and SPI3 support up to two peripherals, and SPI4 supports only one peripheral.

---

**NOTE:** In this chapter,  $m = [1,4]$  represents the module instance and  $x$  represents the channel in signal and register naming. There MCSPi has four instances, with each module instance having different channel numbers:

- SPI1: 4 channels (if  $m = 1, x = 4$ )
  - SPI2: 2 channels (if  $m = 2, x = 2$ )
  - SPI3: 1 channel (if  $m = 3, x = 1$ )
  - SPI4: 1 channel (if  $m = 4, x = 1$ )
-

Figure 23-85. Multichannel Modules SPI1, SPI2, SPI3, and SPI4

The MCSIPI instances include the following main features:

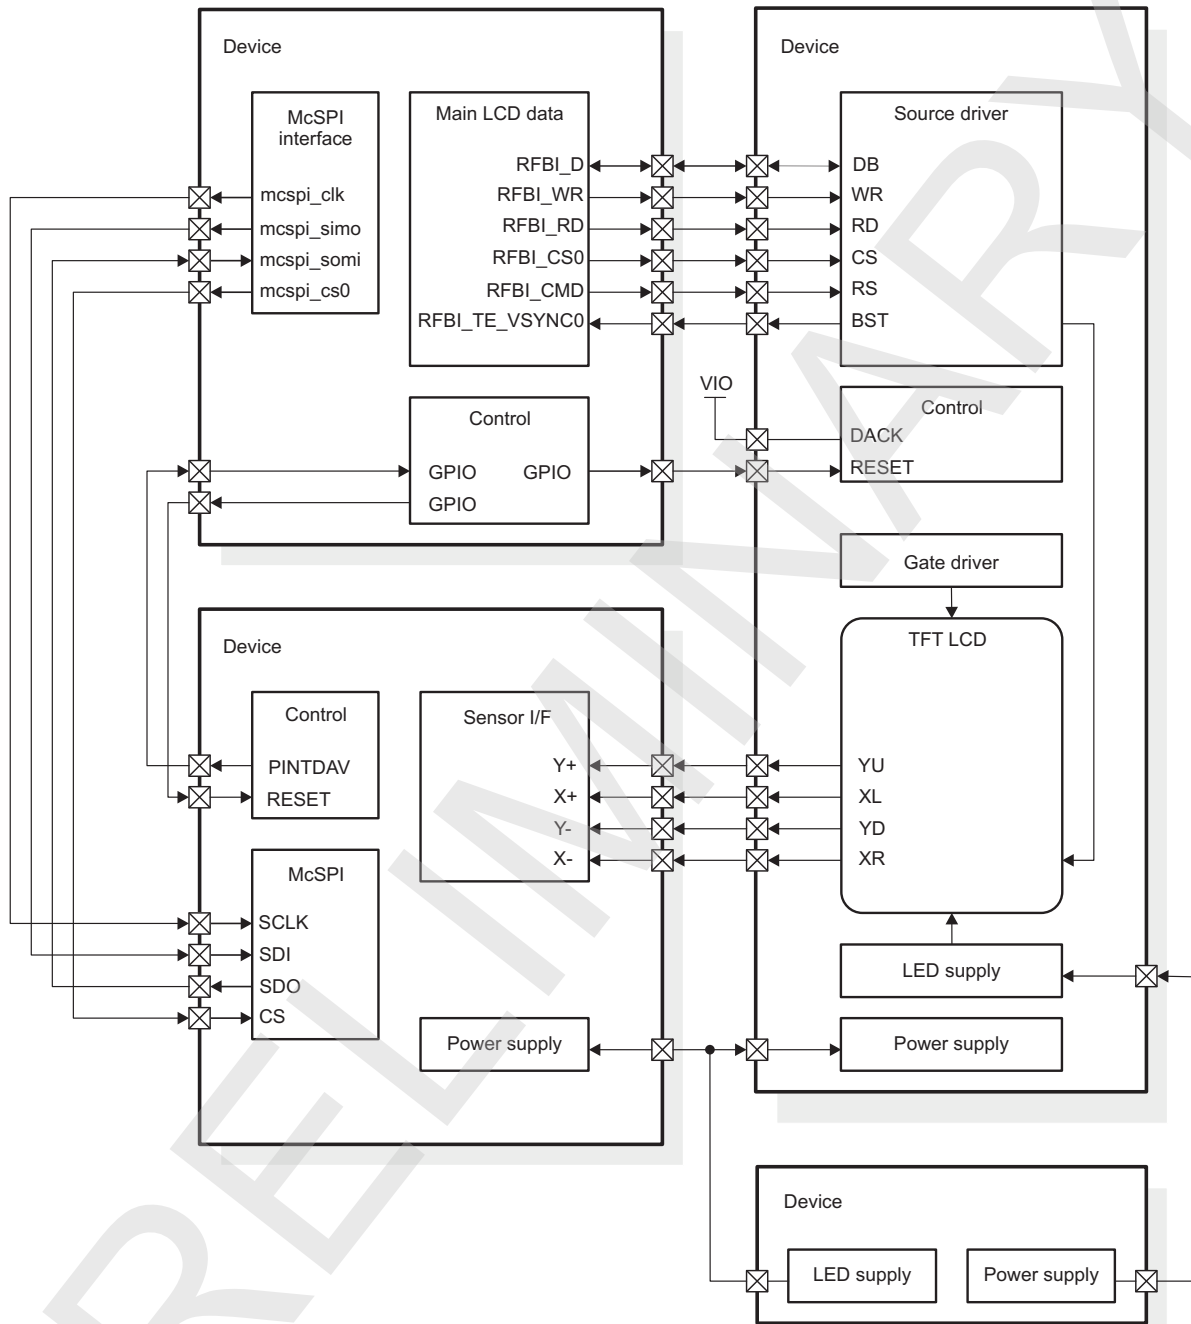

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to four master channels, or single channel in slave mode
- Master multichannel mode:
  - Full duplex/half duplex
  - Transmit-only/receive-only/transmit-and-receive modes

- Flexible I/O port controls per channel
- Two direct memory access (DMA) requests (read/write) per channel
- Single interrupt line for multiple interrupt source events
- Power management through wake-up capabilities
- Enable the addition of a programmable start-bit for SPI transfer per channel (start-bit mode)
- Supports start-bit write command
- Supports start-bit pause and break sequence
- 64-byte built-in FIFO available for a single channel
- Force CS mode for continuous transfers

### 23.4.2 MCSPi Environment

Figure 23-86 shows a simplified overview of a typical application system using the MCSPi. This example is based on a TFS chip set, including a 2.2-inch color-active matrix thin-film transistor (TFT) liquid crystal display (LCD) with a light-emitting diode (LED) front light, a four-wire resistive touch-screen panel, and LCD controllers. This chip set is associated with a touch-screen controller, powered by a power-management unit, and driven by the device. The MCSPi device interface is set to master mode; the touch-screen MCSPi controller interface operates in slave mode.

Figure 23-86. Typical Application Using the MCSPi

### 23.4.2.1 MCSPi Interface

#### 23.4.2.1.1 Basic MCSPi Pins for Master Mode

Figure 23-87 shows all of the MCSPi interface signals in master mode.

**Figure 23-87. MCSPi Interface Signals in Master Mode**

Table 23-262 describes the MCSPi I/O in master mode.

**Table 23-262. MCSPi I/O Description (Master Mode)**

Signal Name	I/O	Description	Reset <sup>(1)</sup>
mcspim_clk	O	SPIm module serial clock <sup>(2)</sup>	Unknown
mcspim_simo	O	SPIm module serial data master out (slave input, master output)	Unknown
mcspim_somi	I	SPIm module serial data master input (slave output, master input)	-
mcspim_csx	O	SPIm module chip-select x output	Low

<sup>(1)</sup> After reset, the SPI modules are in slave mode by default. This paragraph implies that the MCSPi module is configured in slave mode. (See the MCSPi\_MODULCTRL[2] MS bit in the module control register [MCSPi\_MODULCTRL]).

<sup>(2)</sup> This output signal is also used as re-timing input.

#### 23.4.2.1.2 Basic MCSPi Pins for Slave Mode

Figure 23-88 shows all of the MCSPi interface signals in slave mode.

**Figure 23-88. MCSPi Interface Signals in Slave Mode**

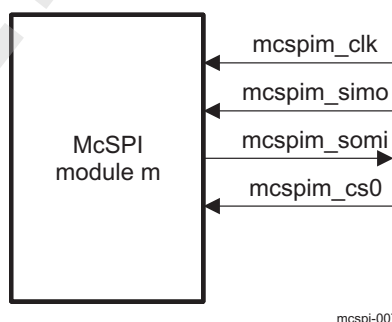

Table 23-263 describes the MCSPi I/O in slave mode.

**Table 23-263. MCSPi I/O Description (Slave Mode)**

Signal Name	I/O	Description	Reset <sup>(1)</sup>
mcspim_clk	I	SPIm module serial clock	Unknown

<sup>(1)</sup> After reset, the SPI modules are in slave mode by default. This paragraph implies that the MCSPi module is configured in slave mode. (See the MCSPi\_MODULCTRL[2] MS bit in the module control register (MCSPi\_MODULCTRL).)

**Table 23-263. MCSPI I/O Description (Slave Mode) (continued)**

Signal Name	I/O	Description	Reset <sup>(1)</sup>
mcspim_simo	I	SPIm module serial data master out (slave input, master output)	Unknown
mcspim_somi	O	SPIm module serial data master input (slave output, master input)	-
mcspim_csx	I	SPIm module chip-select x output	Low

**23.4.2.1.3 Multichannel SPI Protocol and Data Format**

The synchronous SPI protocol allows a master device to initiate serial data transfers to a slave device. A slave select line (mcspim\_csx) allows selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities.

MCSPi offers the flexibility to modify the following parameters to adapt to the device features:

- Word length  
 MCSPi supports any SPI word ranging from 4 bits to 32 bits long (SPIm.MCSPi\_CHxCONF[11:7] WL field).  
 SPI word length can be changed between transmissions to allow the master device to communicate with peripheral slaves that have different requirements.
- SPI enable (mcspim\_csx, for channel x of instance m)  
 The polarity of the SPI enable signals is programmable (SPIm.MCSPi\_CHxCONF[6] EPOL bit). mcspim\_csx signals can be active high or low.  
 The assertion of the mcspim\_csx signals is programmable and can be manually or automatically asserted. The manual assertion mode is available in single master mode only. mcspim\_csx can be kept active between words with the SPIm.MCSPi\_CHxCONF[20] FORCE bit.  
 Two consecutive words for two different slave devices can go along with active mcspim\_csx signals with different polarity. .
- Programmable start-bit  
 In start-bit mode a start-bit is added before the SPI word length to indicate how the next SPI word must be handled. The start-bit is enabled by setting SPIm.MCSPi\_CHxCONF[23] SBE bit to 1. The SPIm.MCSPi\_CHxCONF[24] SBPOL bit defines the polarity of the start-bit.
- Programmable SPI clock
  - Bit rate  
 In master mode, the baud rate of the SPI serial clock is programmable using the 48-MHz reference clock (from the power, reset, and clock management [PRCM] module). Table 23-264 gives the spim\_clk bit rates obtained for data transfer when programming the clock divider (SPIm.MCSPi\_CHxCONF[5:2] CLKD bit field).

**Table 23-264. SPI Master Clock Rates**

Divider	Clock Rate
1	48 MHz
2	24 MHz
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz

**Table 23-264. SPI Master Clock Rates (continued)**

Divider	Clock Rate
4096	~11.7 kHz

– Polarity and phase

The polarity (the SPIm.MCSPi\_CHxCONF[1] POL bit) and the phase (the SPIm.MCSPi\_CHxCONF[0] PHA bit) of the SPI serial clock (mcspim\_clk) are configurable to offer four combinations. Software selects the right combination, depending on the device. See [Table 23-265](#) and [Figure 23-89](#).

**Table 23-265. Phase and Polarity Combinations**

Polarity (POL)	Phase (PHA)	SPI Mode	Comments
0	0	Mode 0	mcspim_clk is active high and sampling occurs on the rising edge.
0	1	Mode 1	mcspim_clk is active high and sampling occurs on the falling edge.
1	0	Mode 2	mcspim_clk is active low and sampling occurs on the falling edge.
1	1	Mode 3	mcspim_clk is active low and sampling occurs on the rising edge.

**Figure 23-89. Phase and Polarity Combinations****23.4.2.1.3.1 Transfer Format**

In master and slave modes, MCSPi drives the data lines when spim\_csx is asserted.

Each word is transmitted starting with the most-significant bit (MSB).

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

- Transmission in mode 0 and mode 2 (PHA = 0)

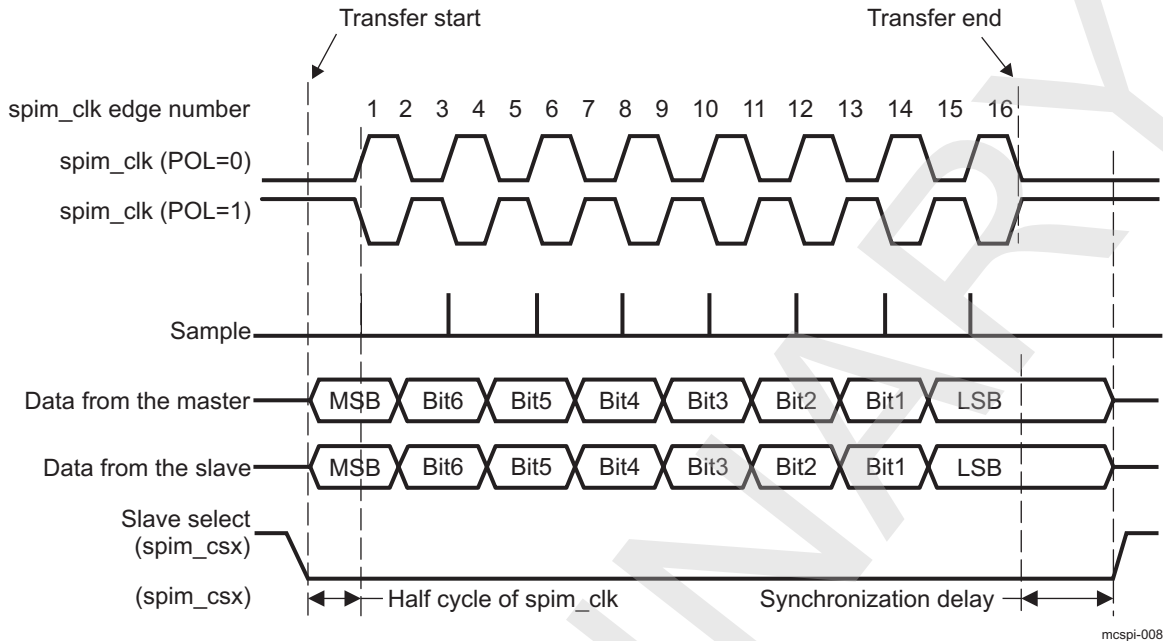

When PHA = 0, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid one half cycle of spim\_clk after the spim\_csx assertion.

Therefore, the first edge of the mcspim\_clk line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

On the next mcspim\_clk edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line.

This process continues for a number of pulses on the spim\_clk line defined by the SPI word length programmed in the master device, with data being latched on odd-numbered edges and shifted on even-numbered edges. See [Figure 23-90](#).

**Figure 23-90. Full-Duplex Transfer Format With PHA = 0**

- Transmission in mode 1 and mode 3 (PHA = 1)

When PHA = 1, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid on the following mcsnim\_clk edge (one half cycle later). This is the sampling edge for the master and slave. A synchronization delay is added between the mcsnim\_csx activation and the first mcsnim\_clk edge.

The received data bit is shifted into the shift register on the third mcsnim\_clk edge.

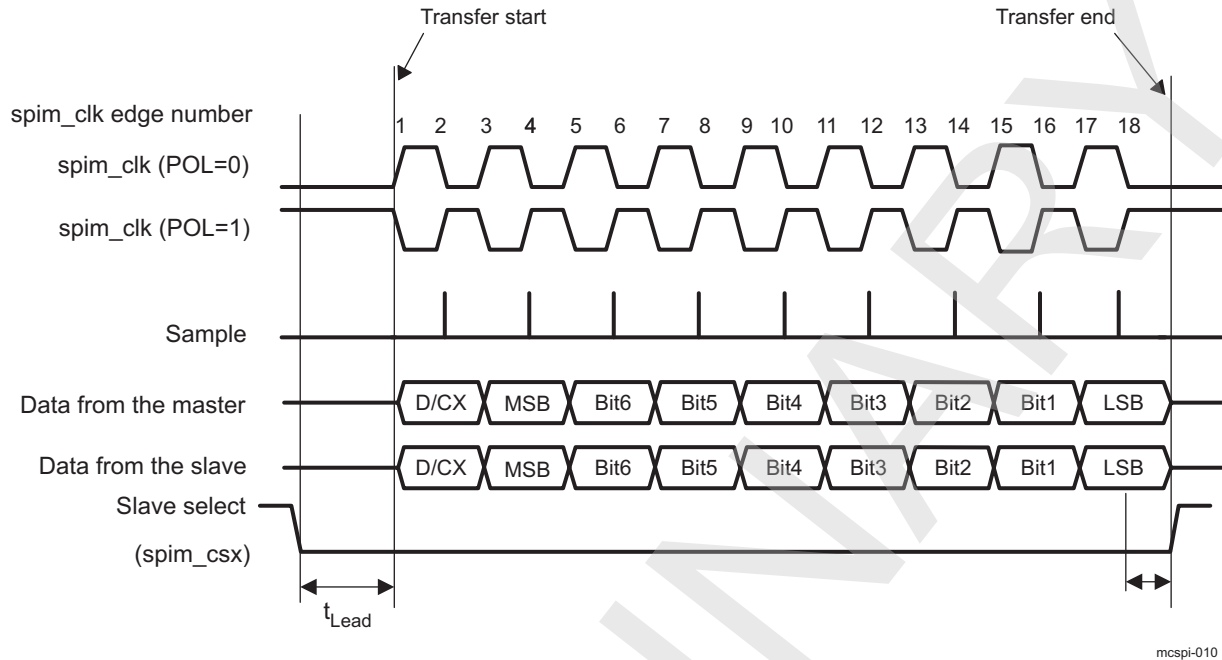

This process continues for a number of pulses on the mcsnim\_clk line defined by the SPI word length programmed in the master device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

**NOTE:** The minimum synchronization delay is one cycle of mcsnim\_clk, if the mcsnim\_clk frequency equals the SPI<sub>m</sub>\_FCLK (MCSPIm functional clock) frequency in master mode. The minimum synchronization delay is one-half cycle of mcsnim\_clk, if the mcsnim\_clk frequency is lower than the SPI<sub>m</sub>\_FCLK frequency in the master and slave modes.

- Transmission with a start-bit (SBE = 1)

When the SPI<sub>m</sub>.MCSPI\_CHxCONF[23] SBE bit = 1, a start-bit is added before the MSB to indicate whether the next SPI word must be handled as a command or as data.

Figure 23-91 shows an example of a data transfer with an extra start-bit.

**Figure 23-91. Extended SPI Transfer With a Start-Bit (SBE = 1)**

### 23.4.2.2 SPI in Master Mode

Figure 23-92 shows a case in master mode (full-duplex) where the MCSPi module is connected with two slave devices.

**Figure 23-92. MCSPi Master Mode (Full-Duplex)**

**NOTE:** In this case  $m = [1,3]$ .

Figure 23-93 shows the master single mode, which can also be configured in receive-only mode.

Figure 23-93. MCSPi Master Single Mode (Receive-Only)

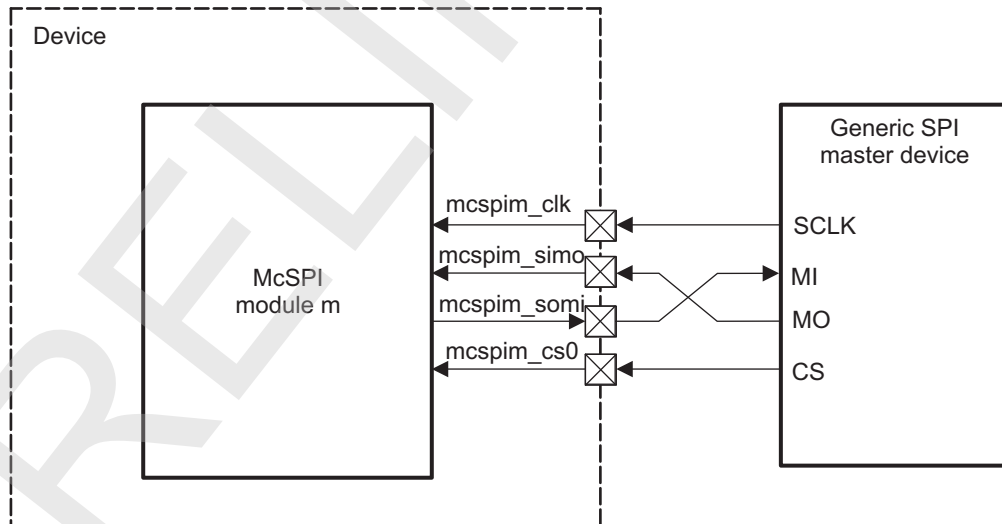

mcspi-003

### 23.4.2.3 SPI in Slave Mode

Figure 23-94 shows a case in slave mode (full-duplex).

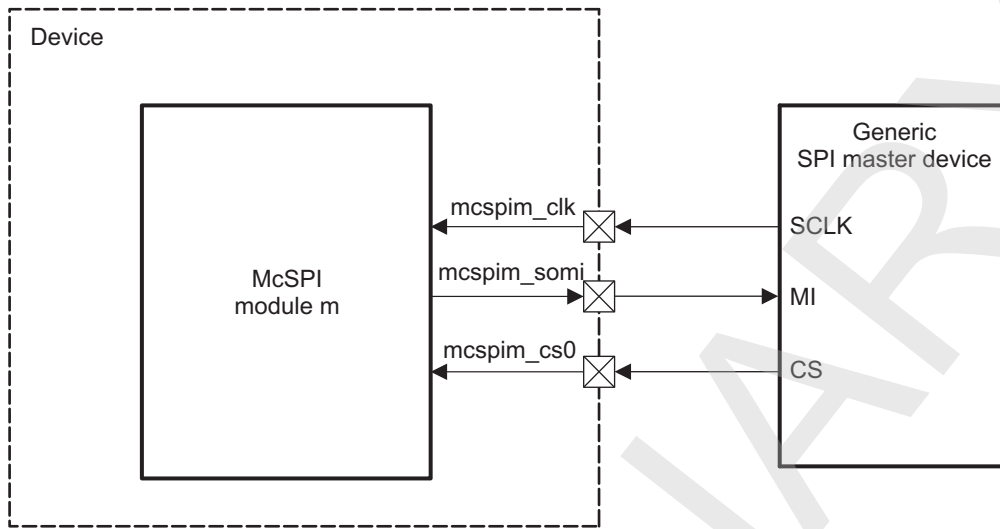

**NOTE:** Only channel 0 can be configured as slave, but the chip-enable signal can be connected to any mcspim\_csx pin and then rerouted internally to channel 0 (SPIm.MCSPi\_CHxCONF[22:21] SPIENSLV bit field [where x = 0]). For more information, see Section 23.4.4.3, *Slave Mode*.

SPI3	1	spi3_cs0	SPI3_SWAKEUP	Destination is the PRCM module.
SPI4	1	spi4_cs0	SPI4_SWAKEUP	Destination is the PRCM module.

### 23.4.4 MCSPi Functional Description

#### 23.4.4.1 MCSPi Block Diagram

Figure 23-97 shows the MCSPi module.

Figure 23-97. MCSPi Block Diagram

mcs pi-012

## 23.4.4.2 Master Mode

### 23.4.4.2.1 Master Mode Features

The MCSPI master mode supports multichannel communication with up to four independent SPI communication channel contexts. The MCSPI initiates a data transfer on the data lines (mcs pim\_simo and mcs pim\_somi) and generates clock (mcs pim\_clk) and control signals (mcs pim\_csx).

Connected to multiple external devices, the MCSPI exchanges data with one SPI device at a time through two main modes (available in slave mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of MCSPI.

Three interrupt events can be used for data transmission and reception in master mode (for more information about interrupts, see [Section 23.4.4.5.1, Interrupt Events in Master Mode](#)).

### 23.4.4.2.2 Master Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on mcs pim\_simo) and received (shifted in serially on mcs pim\_somi) simultaneously on separate data lines.

The master transmit-and-receive mode is programmable per channel (the SPIm.MCSPI\_CHxCONF[13:12] TRM field).

Channel access to the shift registers for transmission/reception is based on the MCSPI\_TXx transmitter register state, the MCSPI\_RXx receiver register state, and round robin arbitration.

Channels that meet the following rules are included in the round-robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

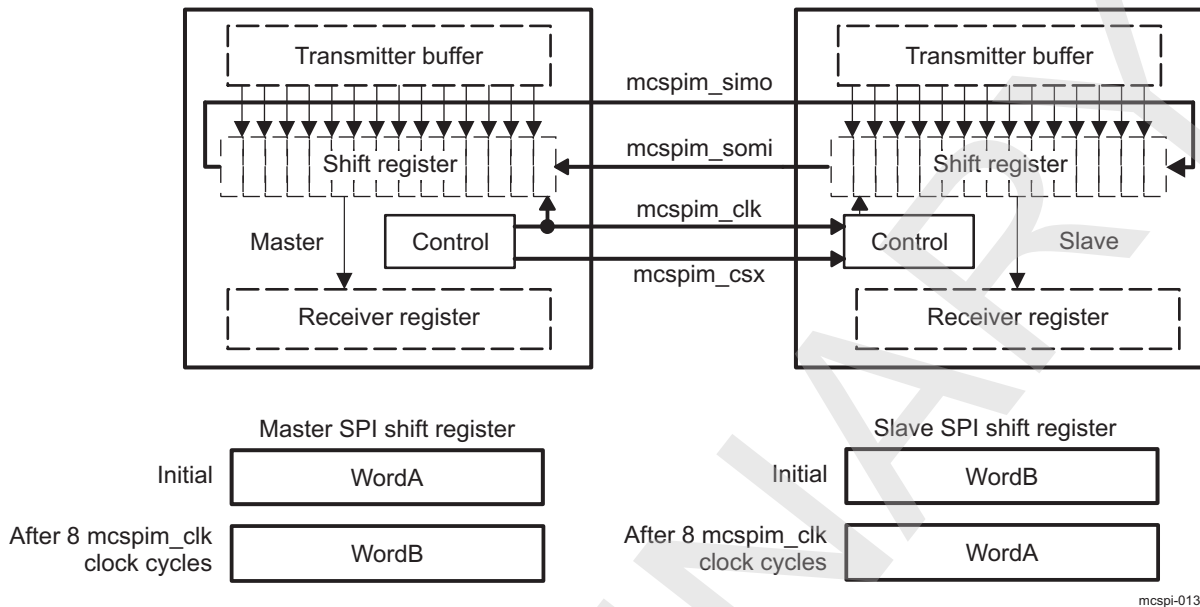

- Rule 1: Only enabled channels (the SPIm.MCSPI\_CHxCTRL[0] EN bit) can be scheduled for transmission and/or reception.
- Rule 2: If its MCSPI\_TXx transmitter register is not empty (the SPIm.MCSPI\_CHxSTAT[1] TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the MCSPI\_TXx register is empty when the shift register is assigned, the TXx\_UNDERFLOW event is activated, and the next enabled channel with new data to transmit is scheduled (see also the transmit-only mode).
- Rule 3: An enabled channel can be scheduled if its receive register is not full (the SPIm.MCSPI\_CHxSTAT[0] RXS bit) when the shift register is assigned (see also the receive-only mode). Therefore, the MCSPI\_RXx register cannot be overwritten. The SPI1.MCSPI\_IRQSTATUS[3] RX0\_OVERFLOW bit is never set to this mode.

When SPI word transfer completes (the SPIm.MCSPI\_CHxSTAT[2] EOT bit is set), the updated MCSPI\_TXx register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (mcs pim\_clk) synchronizes shifting and sampling of the information on the two serial data lines (mcs pim\_simo and mcs pim\_somi). Each time a bit transfers out from the master, 1 bit transfers in from the slave.

[Figure 23-98](#) shows an example of a full-duplex system with a master device (MCSPI module *m*) on the left and a slave device on the right. After eight cycles of the serial clock mcs pim\_clk, WordA transfers from the master to the slave. At the same time, WordB transfers from the slave to the master.

Figure 23-98. SPI Full-Duplex Transmission (Example)

mcs pi-013

### 23.4.4.2.3 Master Transmit-Only Mode (Half Duplex)

The master transmit-only mode prevents the MPU from reading the `MCSPI_RXx` register (minimizing data movement) when only transmission is meaningful.

The master transmit-only mode is programmable per channel (the `SPIm.MCSPI_CHxCONF[13:12]` TRM field). Transmission starts only after data is loaded into the `MCSPI_TXx` register.

Rule 1 and Rule 2, defined in Section 23.4.4.2.2, are applicable in this mode.

Rule 3, defined in Section 23.4.4.2.2, is not applicable.

In master transmit-only mode, the `MCSPI_RXx` register state FULL does not prevent transmission and the `MCSPI_RXx` register is always overwritten with the new SPI word. This event is not significant when only transmission is meaningful. Thus, the `RX0_OVERFLOW` bit in the `SPIm.MCSPI_IRQSTATUS` register is never set in this mode.

The hardware automatically disables the `RX_FULL` interrupt and the DMA read requests.

The transfer status is given by the `SPIm.MCSPI_CHxSTAT[2]` EOT bit.

### 23.4.4.2.4 Master Receive-Only Mode (Half Duplex)

The master receive mode prevents the MPU from refilling the `MCSPI_TXx` register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (the `SPIm.MCSPI_CHxCONF[13:12]` TRM field).

The master receive-only mode enables channel scheduling only on the empty state of the `MCSPI_RXx` register.

Rule 1 and Rule 3, defined in Section 23.4.4.2.2, are applicable in this mode.

Rule 2, defined in Section 23.4.4.2.2, is not applicable.

In the master receive-only mode, software must write dummy data to the `MCSPI_TXx` register. Only one dummy write is enough to receive any number of words from the slave. Software should ensure that the `MCSPI_TXx` register is always full (the `TXx_EMPTY` bits of `SPIm.MCSPI_IRQSTATUS`) when receiving. The content of the `MCSPI_TXx` register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the `MCSPI_TXx` register, the `TXx_EMPTY` and `TXx_UNDERFLOW` bits in the `SPIm.MCSPI_IRQSTATUS` register are never set in receive-only mode.

The SPIm.MCSPI\_CHxSTAT[2] EOT bit gives the status of serialization. The RXx\_FULL bits of the SPIm.MCSPI\_IRQSTATUS register are set when received data is loaded from the shift register to the corresponding MCSPI\_RXx register. The SPIm.MCSPI\_IRQSTATUS[3] RX0\_OVERFLOW bit is never set in this mode.

#### 23.4.4.2.5 Single-Channel Master Mode

When the MCSPI is configured as a master device with a single enabled channel, the assertion of the mcsnim\_csx signal can be controlled in two different ways:

- If the MCSPI\_MODULCTRL[0] SINGLE bit is set to 0, mcsnim\_csx assertion/deassertion after each SPI word is automatically controlled by the MCSPI module (see subsections of Section 23.4.4.2.1, *Master Mode Features*).
- If the MCSPI\_MODULCTRL[0] SINGLE bit and the MCSPI\_CHxCONF[20] FORCE bit are set to 1: mcsnim\_csx assertion/deassertion is controlled by software (see Section 23.4.4.2.5.1, *Programming Tips When Switching to Another Channel*).

##### 23.4.4.2.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for completion of the SPI word transfer (wait until the SPIm.MCSPI\_CHxSTAT[2] EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel first, and then enable the other channel.

##### 23.4.4.2.5.2 Force mcsnim\_csx Mode

Continuous transfers are allowed manually by keeping the mcsnim\_csx signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the mcsnim\_csx line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the mcsnim\_csx active mode is supported when:

- A single channel is used (with the SPIm.MCSPI\_MODULCTRL[0] SINGLE bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (SPIm.MCSPI\_CHxCONF).

The state of the mcsnim\_csx signal is programmable.

- Writing 1 to the SPIm.MCSPI\_CHxCONF[20] FORCE bit drives the mcsnim\_csx line high when the SPIm.MCSPI\_CHxCONF[6] EPOL bit is set to 0. mcsnim\_csx is driven low when the SPIm.MCSPI\_CHxCONF[6] EPOL bit is set to 1.
- Writing 0 to the SPIm.MCSPI\_CHxCONF[20] FORCE bit drives the mcsnim\_csx line low when the SPIm.MCSPI\_CHxCONF[6] EPOL bit is set to 0. mcsnim\_csx is driven high when the SPIm.MCSPI\_CHxCONF[6] EPOL bit is set to 1.
- A single channel is enabled (the SPIm.MCSPI\_CHxCTRL[0] EN bit is set to 1). The first enabled channel activates the mcsnim\_csx line.

When the channel is enabled, the mcsnim\_csx signal activates with the programmed polarity. As in the multichannel master mode, the transfer start depends on the status of the MCSPI\_TXx register (the SPIm.MCSPI\_CHxSTAT[1] TXS bit), the status of the MCSPI\_RXx register (the SPIm.MCSPI\_CHxSTAT[1] RXS bit), and the defined mode (the SPIm.MCSPI\_CHxCONF[13:12] TRM field) of the channel enabled.

The SPIm.MCSPI\_CHxSTAT[2] EOT bit gives the transfer status of each SPI word. The RXx\_FULL bit in the SPIm.MCSPI\_IRQSTATUS register is set when received data is loaded from the shift register to the MCSPI\_RXx register.

A change in the configuration parameters is propagated directly on the SPI interface. If the mcsnim\_csx signal is activated, ensure that the configuration is changed only between SPI words to avoid corrupting the current transfer.

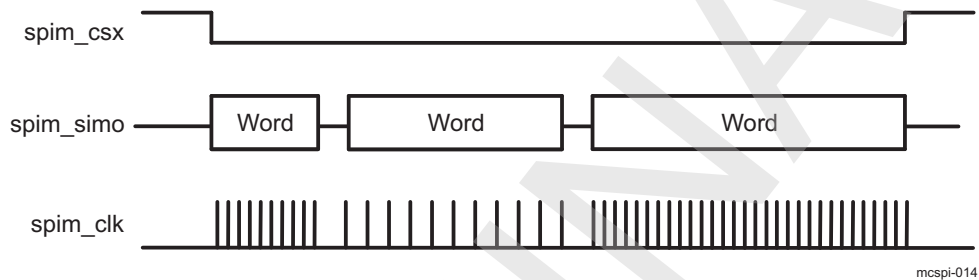

**NOTE:** To avoid data corruption, `mcs pim_clk` phase and `mcs pim_clk` polarity must not be modified when the `mcs pim_csx` signal is activated.

A delay between SPI words that requires the connected SPI slave device to switch from one configuration (transmit-only for instance) to another (receive-only for instance) must be handled by software.

At the end of the last SPI word, the channel must be deactivated (the `SPI m.MCSPi_CHxCTRL[0]` EN bit set to 0) and `mcs pim_csx` can be forced to its inactive state using the `SPI m.MCSPi_CHxCONF[20]` FORCE bit.

Figure 23-99 and Figure 23-100 show successive transfers with `mcs pim_csx` maintained active low with a different configuration for each SPI word in single-data-pin and dual-data-pin interface modes, respectively.

**Figure 23-99. Continuous Transfers With `mcs pim_csx` Maintained Active (Single-Data-Pin Interface Mode)**

**Figure 23-100. Continuous Transfers With `mcs pim_csx` Maintained Active (Dual-Data-Pin Interface Mode)**

**NOTE:** The turbo mode described in Section 23.4.4.2.5.3, *Turbo Mode*, maintains `mcs pim_csx` in active mode when the following conditions are met:

- A single channel is explicitly used (the `SPI m.MCSPi_MODULCTRL[0]` SINGLE bit is set to 1).
- Turbo mode is enabled in the configuration of the channel. (The `SPI m.MCSPi_CHxCONF[19]` TURBO bit is set to 1.)

### 23.4.4.2.5.3 Turbo Mode

Turbo mode improves the throughput of the SPI interface when a single channel is enabled by allowing transfers until the shift register and the `MCSPi_RXx` register are full. Turbo mode is useful (time saving) when a transfer exceeds two words. This mode is programmable per channel (through the `SPI1.MCSPi_CHxCONF[9]` TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 apply, but Rule 3 does not (see Section 23.4.4.2.2). An enabled channel can be scheduled if its receive register is full (the `SPI m.MCSPi_CHxSTAT[0]` RXS bit) at the time of the shift-register assignment until the shift register is full.

The `MCSPi_RXx` register cannot be overwritten in turbo mode. Consequently, the `SPIm.MCSPi_IRQSTATUS[3] RX0_OVERFLOW` bit is never set in this mode.

#### 23.4.4.2.6 Start-Bit Mode

In start-bit mode, an extended bit is added before the SPI word to indicate whether the next SPI word must be handled as a command or as data. This feature is available only in master mode. Start-bit mode cannot be used at the same time as turbo mode and/or force `mcsxim_csx` mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the `SPIm.MCSPi_CHxCONF[23] SBE` bit to 1. The polarity of the extended bit is programmable per channel. When the `SPIm.MCSPi_CHxCONF[24] SBPOL` bit is set to 0, the SPI word must be handled as a command. When the `SPIm.MCSPi_CHxCONF[24] SBPOL` bit is set to 1, the SPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start-bit transfer without disabling the channel for reconfiguration; in this case, users must configure the `SPIm.MCSPi_CHxCONF[24] SBPOL` bit before writing the SPI word to be transmitted to the TX register.

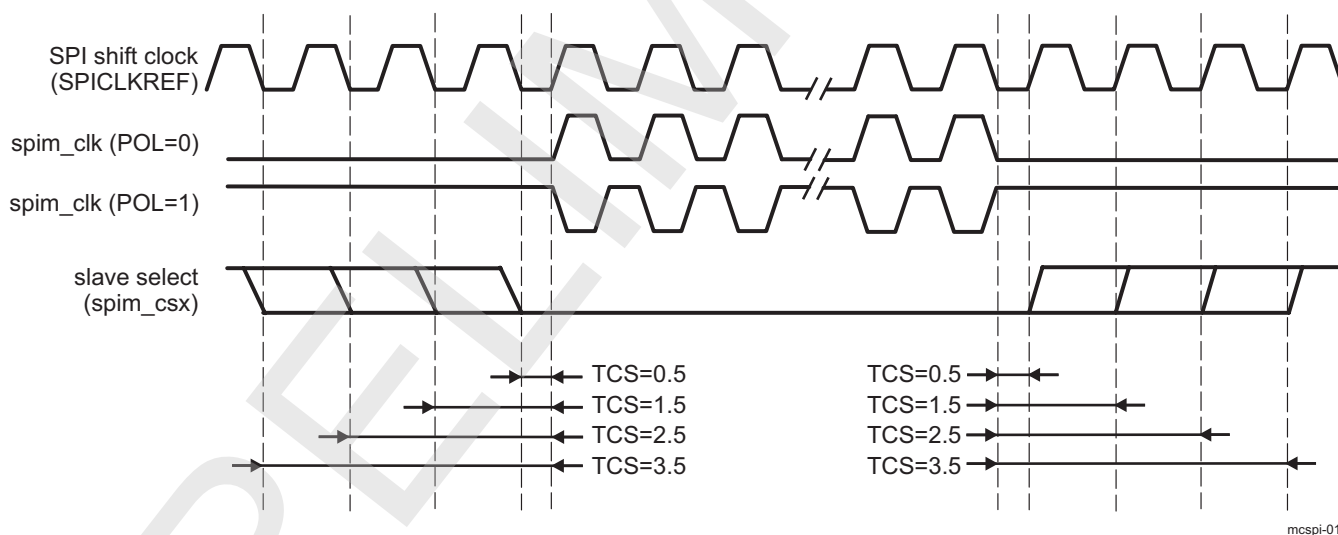

#### 23.4.4.2.7 Chip-Select Timing Control

The chip-select (CS) timing control is available only in master mode with automatic CS generation (the `MCSPi_MODULCTRL[0] SINGLE` bit field set to 0) to add a programmable delay between CS assertion and first clock edge, or CS removal and last clock edge.

This mode is programmable per channel (the `TCS` bit of the `SPIm.MCSPi_CHxCONF` register).

Figure 23-101 shows the CS SPIEN timing control.

**Figure 23-101. CS SPIEN Timing Controls**

**NOTE:** Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between CS assertion and the first clock edge with `PHA = 1` or between CS removal and the last clock edge with `PHA = 0`.

#### 23.4.4.2.8 Programmable SPI Clock (`mcsxim_clk`)

In master mode, the baud rate of the SPI serial clock is programmable.

An internal reference clock, `SPIm_FCLK`, is used as input of a programmable divider (the `SPIm.MCSPi_CHxCONF[5:2] CLKD` bit field) to generate the bit rate of the serial output clock `mcsxim_clk`. Table 23-270 summarizes the supported divisor values.

**Table 23-270. SPI Master Clock Rates**

Divider	Clock Rate
1	48 MHz
2	24 MHz
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz
8192 and higher: Division not supported	-

**23.4.4.2.8.1 Clock Ratio Granularity**

By default, the clock division ratio is defined by the SPIm.MCSPi\_CHxCONF[5:2] CLKD bit field with power-of-two granularity leading to a clock division in the range 1 to 4096; in this case, the duty cycle is always 50 percent. With the SPIm.MCSPi\_CHxCONF[29] CLKG bit, clock division granularity can be changed to one clock cycle; in that case the SPIm.MCSPi\_CHxCTRL[15:8] EXTCLK bit field is concatenated with the SPIm.MCSPi\_CHxCONF[5:2] CLKD bit field to give a 12-bit-wide division ratio in the range 1 to 4096.

When granularity is one clock cycle (CLKG set to 1), for the odd value of the clock ratio, the clock high level lasts one clock cycle more than the low level, depending on the SPIm.MCSPi\_CHxCONF[1] POL and SPIm.MCSPi\_CHxCONF[0] PHA bits (see Table 23-271).

**Table 23-271. CLKSPiO High/Low Time Computation**

Clock Ratio Fratio	CLKSPiO High Time	CLKSPiO Low Time
1	T <sub>high_ref</sub>	T <sub>low_ref</sub>
Even >=2	T <sub>ref</sub> * (Fratio/2)	T <sub>ref</sub> * (Fratio/2)
Odd >= (POL=PHA)	T <sub>ref</sub> * (Fratio - 1)/2	T <sub>ref</sub> * (Fratio + 1)/2
Odd >= (POL != PHA)	T <sub>ref</sub> * (Fratio + 1)/2	T <sub>ref</sub> * (Fratio - 1)/2

**NOTE:** Fratio = spi1\_clk frequency (Fout) division ratio.  
 T<sub>high</sub> = spi1\_clk high time period.  
 T<sub>low</sub> = spi1\_clk low time period.  
 T<sub>ref</sub> = SPI1\_FCLK period.  
 T<sub>high\_ref</sub> = SPI1\_FCLK high time period.  
 T<sub>low\_ref</sub> = SPI1\_FCLK low time period.

If CLKG = 1: Fratio = EXTCLK concatenated with CLKD + 1

For odd ratio values, the duty cycle is calculated as follows:

$$\text{Duty\_cycle} = (1 - 1/\text{Fratio})/2$$

Table 23-272 shows examples of clock granularity with a clock source frequency of 48 MHz.

**Table 23-272. Clock Granularity Examples**

EXTCLK	CLKD	CLKG	Fratio	PHA	POL	Thigh (ns)	Tlow (ns)	Tperiod (ns)	Duty Cycle	Fout (MHz)
X	0	0	1	X	X	10.4	10.4	20.8	50–50	48
X	1	0	2	X	X	20.8	20.8	41.6	50–50	24
X	2	0	4	X	X	41.6	41.6	83.2	50–50	12
X	3	0	8	X	X	83.2	83.2	166.4	50–50	6
0	0	1	1	X	X	10.4	10.4	20.8	50–50	48
0	1	1	2	X	X	20.8	20.8	41.6	50–50	24
0	2	1	3	1	0	41.6	20.8	62.4	66–33	16
0	2	1	3	1	1	20.8	41.6	62.4	33–66	16
0	3	1	4	X	X	41.6	41.6	83.2	50–50	12
5	0	1	81	1	0	852.8	832	1684.8	50.6–49.4	0.592
5	7	1	88	X	X	915.2	915.2	1830.4	50–50	0.545

#### 23.4.4.3 Slave Mode

To select the MCSPi slave mode, set the SPI1.MCSPi\_MODULCTRL[2] MS bit.

A MCSPi slave device can be connected to up to four external SPI master devices but handles transactions with one SPI master device at a time.

In slave mode, the MCSPi initiates data transfer on the data lines (mcspim\_simo and mcspim\_somi) when it is selected by an active control signal (mcspim\_csx) and receives an SPI clock (mcspim\_clk) from the external SPI master device. Only channel 0 can be configured as a slave. In slave mode, the MCSPi uses the edge of mcspim\_csx to detect word length. For this reason, mcspim\_csx must become inactive between each word.

The MCSPi does not support mcspim\_csx active between SPI words. It uses the edge to detect word length.

##### 23.4.4.3.1 Dedicated Resources

Only channel 0 can be enabled in slave mode. In this section register names such as SPI1.MCSPi\_CHxCTRL stand for SPI1.MCSPi\_CH0CTRL, where x = 0 (channel 0 control register).

Figure 23-102 shows an example of four slaves wired on a single master device.

Figure 23-102. Example of MCSPi Slave With One Master and Multiple Slave Devices on Channel 0

The channel 0 in slave mode has the following resources:

- Its own channel enable, programmable with the SPIm.MCSPi\_CHxCTRL[0] EN bit (where x = 0). This channel must be enabled before transmission and reception.
- For this mode, the slave-select signal can be detected on any one of the mcspim\_csx ports. This is programmable with the SPIm.MCSPi\_CHxCONF[22:21] SPIENSLV bit field (where x = 0).
- Its own transmitter register, SPIm.MCSPi\_TXx (where x = 0), on top of the common transmit shift register. If the MCSPi\_TXx register is empty, the SPIm.MCSPi\_CHxSTAT[1] TXS bit (where x = 0) is set. If MCSPi is selected by an external master (the active signal on the mcspim\_csx port assigned to channel 0), the MCSPi\_TXx register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The MCSPi\_TXx register must be loaded before MCSPi is selected by a master.
- Its own receiver register, SPIm.MCSPi\_RXx (where x = 0), on top of the common receive shift register. If the MCSPi\_RXx register is full, the SPIm.MCSPi\_CHxSTAT[0] RXS bit (where x = 0) is set.

**NOTE:** The MCSPi\_TXx register and MCSPi\_RXx registers of the other channels are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the SPIm.MCSPi\_CHxCONF register (where x = 0):
  - Transmit and receive modes, programmable with the TRM field
  - Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The SPIm modules are in slave mode after reset and must be properly configured for the modules to act in master mode.)
  - SPI word length, programmable with the WL bit

- mcspim\_csx polarity, programmable with the EPOL bit
- mcspim\_clk polarity, programmable with the POL bit
- mcspim\_clk phase, programmable with the PHA bit

The mcspim\_clk frequency of a transfer is controlled by the external SPI master connected to the MCSPi slave device. The SPIm.MCSPi\_CHxCONF[5:2] CLKD bit field (where x = 0) is not used in slave mode.

---

**NOTE:** The configuration of the channel can be loaded in the SPIm.MCSPi\_CHxCONF register (where x = 0) only when the channel is disabled.

---

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of MCSPi. DMA requests are asserted using the SPIm.MCSPi\_CHxCONF[15] DMAR bit (where x = 0) for reading and the SPIm.MCSPi\_CHxCONF[14] DMAW bit (where x = 0) for writing.
- Four interrupt events (see [Section 23.4.4.5.2, Interrupt Events in Slave Mode](#))

#### 23.4.4.3.2 Slave Transmit-and-Receive Mode

The slave receive mode is programmable (set the SPIm.MCSPi\_CHxCONF[13:12] TRM bit field [where x = 0] to 0x0).

In slave transmit-and-receive mode, the MCSPi\_TXx register must be loaded before MCSPi is selected by an external SPI master device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The MCSPi\_TXx register content is always loaded in the shift register whether it is updated or not. The event TXx\_UNDERFLOW is activated accordingly and does not prevent transmission.

When an SPI word transfer completes (the SPIm.MCSPi\_CHxSTAT0[2] EOT bit [where x = 0] set to 1), the received data is transferred to the channel receive register.

To use MCSPi as a slave transmit-only device, the RXx\_FULL and RX0\_OVERFLOW interrupts and DMA read requests must be disabled due to the MCSPi\_RXx register state (see [Section 23.4.4.5.2, Interrupt Events in Slave Mode](#)).

#### 23.4.4.3.3 Slave Transmit-Only Mode

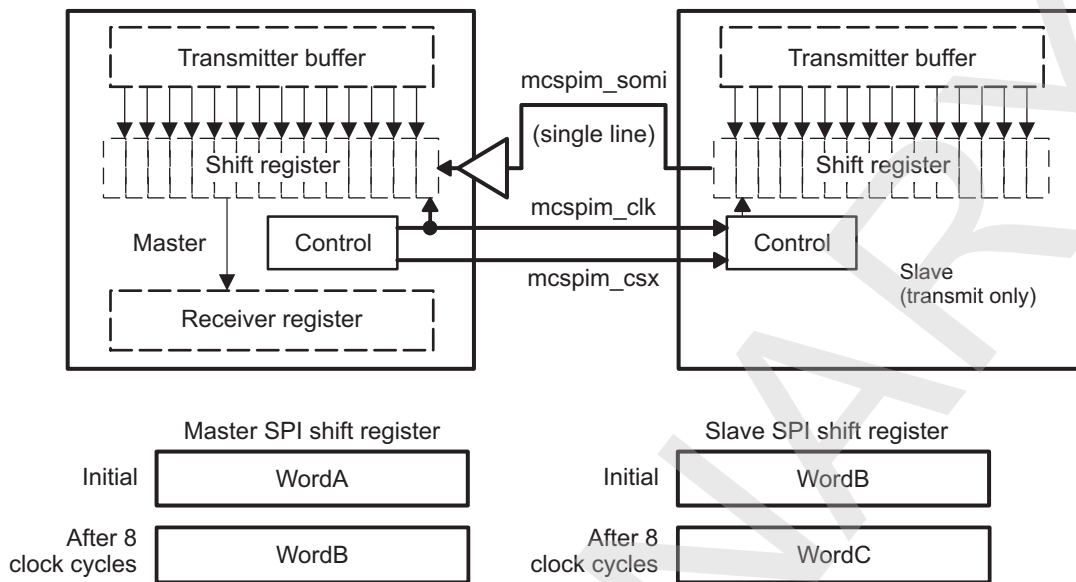

The slave transmit-only mode is programmable (set the SPIm.MCSPi\_CHxCONF[13:12] TRM bit field [where x = 0] to 0x2) and avoids the requirement for the MPU to read the MCSPi\_RXx register (minimizing data movement) only when transmission is meaningful.

To use the MCSPi as a slave transmit-only device, the RXx\_FULL and RX0\_OVERFLOW interrupts and DMA read requests must be disabled because of the MCSPi\_RXx register state.

When the SPI word transfer completes, the SPIm.MCSPi\_CHxSTAT[2] EOT bit is set (where x = 0).

[Figure 23-103](#) shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave device, 1 bit transfers in the master. After eight cycles of the serial clock mcspim\_clk, WordB transfers from the slave to the master.

Figure 23-103. SPI Half-Duplex Transmission (Transmit-Only Slave)

#### 23.4.4.3.4 Slave Receive-Only Mode

The slave receive mode is programmable (set the `SPI m.MCSPI_CHxCONF[13:12]` TRM bit field [where  $x = 0$ ] to 0x1).

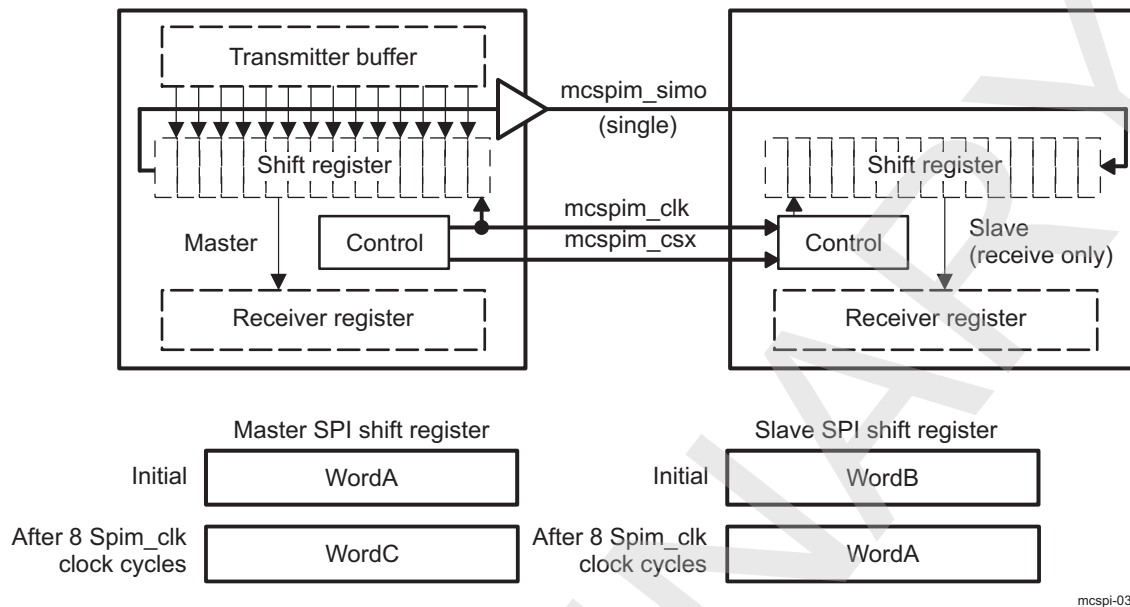

In receive-only mode, the `MCSPI_Tx` register must be loaded before the MCSPi is selected by an external SPI master device. The `MCSPI_Tx` register content is always loaded into the shift register whether it is updated or not. The `Tx_UNDERFLOW` event is activated accordingly and does not prevent transmission.

When an SPI word transfer completes (the `SPI m.MCSPI_CHxSTAT0[2]` EOT bit [where  $x = 0$ ] is set to 1), the received data is transferred to the channel receive register.

To use the MCSPi as a slave receive-only device, the `Tx_EMPTY` and `Tx_UNDERFLOW` interrupts and the DMA write requests must be disabled due to the `MCSPI_Tx` register state.

For a full-duplex transmission, the serial clock (`mcs pim_clk`) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If `mcs pim_clk` synchronizes on a single serial data line, the data line should be half-duplex.

Figure 23-104 shows an example of a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time a bit transfers out from the master, 1 bit transfers in from the slave. After eight cycles of the serial clock `mcs pim_clk`, Word A transfers from the master to the slave.

**Figure 23-104. SPI Half-Duplex Transmission (Receive-Only Slave)**

#### 23.4.4.4 FIFO Buffer Management

The MCSPI controller has a built-in 64-byte buffer to unload the DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at a time and is selected by setting the `SPIm.MCSPI_CHxCONF[28] FFER` or `SPIm.MCSPI_CHxCONF[27] FFEW` bits to 1. If several channels are selected and several FIFO enable bit fields are set to 1, the controller forces the buffer not to be used; the driver must set only one FIFO enable bit field.

The buffer can be used in the following modes:

- Master or slave mode
- Transmit-only, receive-only, or transmit/receive mode
- Single channel or turbo mode, or normal round-robin mode. In round-robin mode the buffer is used by only one channel.

Every word length (`SPIm.MCSPI_CHxCONF[11:7] WL`) is supported.

In transmit/receive mode, the buffer can be used in transmit (see [Figure 23-105](#)) or receive (see [Figure 23-106](#)) directions, or in both directions. If only one direction is chosen in transmit/receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two 32-byte buffers, one for each direction. See [Figure 23-107](#).

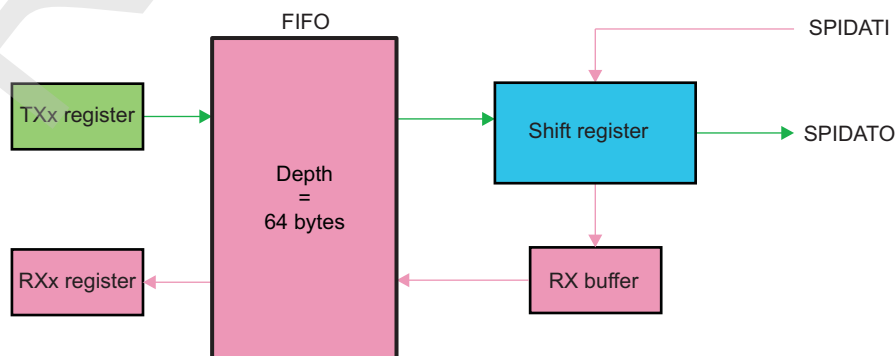

**Figure 23-105. Buffer Used in Transmit Direction Only**

Figure 23-106. Buffer Used in Receive Direction Only

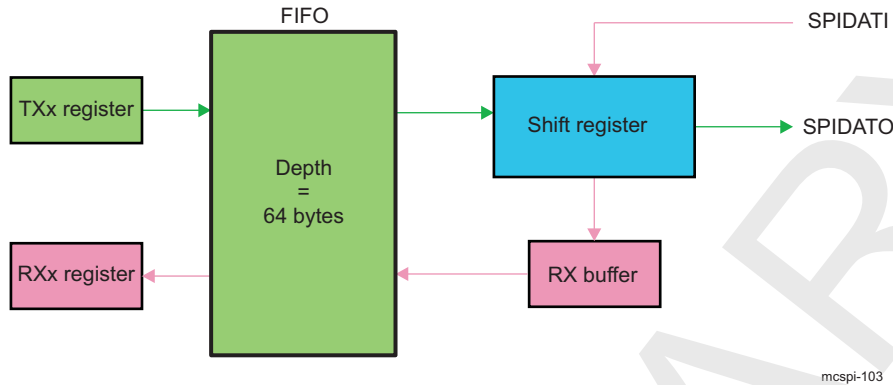

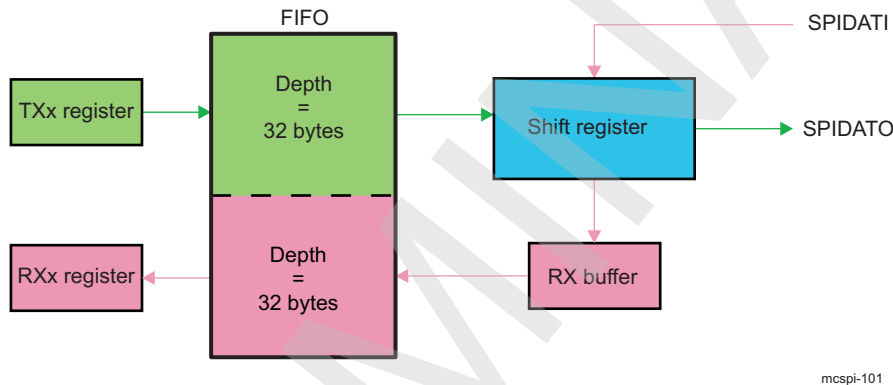

Figure 23-107. Buffer Used for Transmit and Receive Directions

Two levels (SPI<sub>m</sub>.MCSPI\_XFERLEVEL[5:0] AEL and SPI<sub>m</sub>.MCSPI\_XFERLEVEL[13:8] AFL) rule the buffer management. The granularity of these levels is 1 byte; it is not aligned with the SPI word length. The driver must set these values as a multiple of the SPI word length defined in WL. Table 23-273 shows the number of bytes written in the FIFO, depending on the word length.

Table 23-273. FIFO Writes, Word Length Relationship

SPI Word Length WL	3 ≤ WL ≤ 7	8 ≤ WL ≤ 15	16 ≤ WL ≤ 31
Number of byte written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or the FIFO configuration changes.

#### 23.4.4.4.1 Buffer Almost Full

The MCSPI\_XFERLEVEL[15:8] AFL bit field is needed when the buffer is used to receive an SPI word from a slave (the MCSPI\_CHxCONF[28] FFER bit must be set to 1). It defines the almost-full buffer status. See Figure 23-108.

When the FIFO pointer reaches this level an interrupt or a DMA request is sent to the MPU to enable the system to read AFL + 1 bytes from the receive register.

**NOTE:** AFL + 1 must correspond to a multiple value of the MCSPI\_CHxCONF[11:7] WL bit field.

When DMA is used, the request is deasserted after the first receive register read.

No new request will be asserted again as long as the system has not performed the right number of read accesses.

**Figure 23-108. Buffer Almost Full Level (AFL)**

**NOTE:** The [MCSPI\\_IRQSTATUS](#) register bits are not available in DMA mode. In DMA mode, the SPIIm\_DMA\_RXx request is asserted on the same conditions as the [MCSPI\\_IRQSTATUS](#) RXx\_FULL flag.

#### 23.4.4.4.2 Buffer Almost Empty

The [MCSPI\\_XFERLEVEL\[7:0\]](#) AEL bit field is needed when the buffer is used to transmit an SPI word to a slave (the [MCSPI\\_CHxCONF\[27\]](#) FFEW bit must be set to 1). It defines the almost-empty buffer status. See [Figure 23-109](#).

When the FIFO pointer has not reached this level, an interrupt or a DMA request is sent to the MPU to enable the system to write AEL + 1 bytes to the transmit register.

**NOTE:** AEL + 1 must correspond to a multiple value of the [MCSPI\\_CHxCONF\[11:7\]](#) WL bit field.

When DMA is used, the request is deasserted after the first transmit register write.

No new request will be asserted again as long as the system has not performed the right number of write accesses.

**Figure 23-109. Buffer Almost Empty Level (AEL)**

**NOTE:** The [MCSPI\\_IRQSTATUS](#) register bits are not available in DMA mode. In DMA mode, the SPIIm\_DMA\_TXx request is asserted on the same conditions as the [MCSPI\\_IRQSTATUS](#) TXx\_EMPTY flag.

#### 23.4.4.4.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user must previously configure in the [MCSPi\\_XFERLEVEL](#) register the AEL and AFL levels and especially the [MCSPi\\_XFERLEVEL\[31:16\]](#) WCNT bit field to define the number of SPI words to be transferred using the FIFO before enabling the channel.

This counter allows the controller to stop the transfer correctly after a defined number of SPI word transfers. If WCNT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel; in this case, the user does not know how many SPI transfers have been done. For received words, software must poll the CHxSTAT[5] RXFFE bit and read the [MCSPi\\_RXx](#) receive register to empty the FIFO buffer.

When the end-of-word count interrupt is generated (the [MCSPi\\_IRQSTATUS\[17\]](#) EOW bit is set), the user can disable the channel and poll the [MCSPi\\_CHxSTAT\[5\]](#) RXFFE bit to know it lasts SPI words in the FIFO buffer and read them.

No new request will be asserted as long as the system has not performed the right number of write accesses.

#### 23.4.4.5 Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the SPIm.[MCSPi\\_IRQSTATUS](#) register (RXx\_FULL, TXx\_UNDERFLOW, TXx\_EMPTY, ...) [where x = 0, 3] that indicate whether service is required. Each status bit has an interrupt enable bit (a mask) in the SPIm.[MCSPi\\_IRQENABLE](#) register (RXx\_FULL\_ENABLE, TXx\_UNDERFLOW\_ENABLE, TXx\_EMPTY\_ENABLE, ...).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The MCSPi supports interrupt-driven and polling operations.

##### 23.4.4.5.1 Interrupt Events in Master Mode

In master mode, the interrupt events related to the [MCSPi\\_TXx](#) register state are TXx\_EMPTY and TXx\_UNDERFLOW. The interrupt event related to the [MCSPi\\_RXx](#) register state is RXx\_FULL.

###### 23.4.4.5.1.1 TXx\_EMPTY

The TXx\_EMPTY event is activated when a channel is enabled and its [MCSPi\\_TXx](#) register is empty (transient event). Enabling a channel automatically triggers this event, except in master receive-only mode (see [Section 23.4.4.2.4, Master Receive-Only Mode](#)). When the FIFO buffer is enabled (the [MCSPi\\_CHxCONF\[27\]](#) FFEW bit is set to 1), the [MCSPi\\_IRQSTATUS](#) TXx\_EMPTY bit is set as soon as there is enough space in the buffer to write a number of bytes defined by the [MCSPi\\_XFERLEVEL\[5:0\]](#) AEL bit field.

The [MCSPi\\_TXx](#) register must be loaded with data to remove the source of the interrupt; the SPIm.[MCSPi\\_IRQSTATUS](#) TXx\_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx\_EMPTY event will be asserted as soon as the MPU has not performed the number of writes into the [MCSPi\\_TXx](#) register defined by the [MCSPi\\_XFERLEVEL\[5:0\]](#) AEL bit field. The MPU must perform the right number of writes.

###### 23.4.4.5.1.2 TXx\_UNDERFLOW

The event TXx\_UNDERFLOW is activated when the channel is enabled and if the [MCSPi\\_TXx](#) register or the FIFO is empty (not updated with new data) when an external master device starts a data transfer with the MCSPi (transmit and receive).

The TXx\_UNDERFLOW is a harmless warning in master mode.

To avoid having a TXx\_UNDERFLOW event at the beginning of a transmission, the event TXx\_UNDERFLOW is not activated when no data has been loaded into the MCSPI\_TXx register, because the channel has been enabled. To avoid having a TXx\_UNDERFLOW event, the MCSPI\_TXx register must seldom be loaded.

The SPI.MCSPI\_IRQSTATUS TXx\_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if event enabled as the interrupt source).

#### 23.4.4.5.1.3 RXx\_FULL

The RXx\_FULL event is activated when channel is enabled and MCSPI\_RXx register becomes filled (transient event). When the FIFO buffer is enabled (the MCSPI\_CHxCONF[28] FFER bit is set to 1), RXx\_FULL is asserted as soon as the number of bytes holds in the FIFO to be read reaches the MCSPI\_XFERLEVEL[13:8] AFL threshold.

The MCSPI\_RXx register must be read to remove the source of the interrupt; the MCSPI\_IRQSTATUS RXx\_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx\_FULL event will be asserted as soon as the MPU has not performed AFL + 1 reads into MCSPI\_RXx. The MPU must perform the right number of reads.

#### 23.4.4.5.1.4 End Of Word Count

The MCSPI\_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI\_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as MCSPI\_XFERLEVEL[31:16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI\_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event enabled as interrupt source).

#### 23.4.4.5.2 Interrupt Events in Slave Mode

In slave mode, the interrupt events related to the MCSPI\_TXx register state are TXx\_EMPTY and TXx\_UNDERFLOW. The interrupt events related to the MCSPI\_RXx register state are RXx\_FULL and RX0\_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the MCSPI\_IRQSTATUS register.

##### 23.4.4.5.2.1 TXx\_EMPTY

The TXx\_EMPTY event is activated when a channel is enabled and its MCSPI\_TXx register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (the MCSPI\_CHxCONF[27] FFEW bit is set to 1), the TXx\_EMPTY event will be asserted as soon as there is enough space in buffer to write a number of bytes defined by the MCSPI\_XFERLEVEL[5:0] AEL bit field.

The MCSPI\_TXx register must be loaded with data to remove the source of the interrupt; the SPI.MCSPI\_IRQSTATUS TXx\_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx\_EMPTY event will be asserted as soon as the MPU has not performed the number of write into the MCSPI\_TXx register defined by MCSPI\_XFERLEVEL[5:0] AEL bit field. The MPU must perform the right number of writes.

##### 23.4.4.5.2.2 TXx\_UNDERFLOW

The TXx\_UNDERFLOW event is activated when a channel is enabled and if the MCSPI\_TXx register is empty (not updated with new data) when an external master device starts a data transfer with the MCSPI (transmit and receive).

When FIFO is enabled, the data emitted while the underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data in the FIFO has been reset).

TXx\_UNDERFLOW indicates an error (data loss) in slave mode.

To avoid having a TXx\_UNDERFLOW event at the beginning of a transmission, the TXx\_UNDERFLOW event is not activated when data is not loaded into the **MCSPi\_TXx** register because the channel is enabled.

The SPIm.**MCSPi\_IRQSTATUS** TXx\_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### **23.4.4.5.2.3 RXx\_FULL**

The RXx\_FULL event is activated when a channel is enabled and the **MCSPi\_RXx** register is being filled (transient event). When the FIFO buffer is enabled (the **MCSPi\_CHxCONF**[28] FFER bit is set to 1), RXx\_FULL will be asserted as soon as there is a number of bytes holds in buffer to read defined by the **MCSPi\_XFERLEVEL**[13:8] AFL bit field.

The **MCSPi\_RXx** register must be read to remove the source of the interrupt; the SPIm.**MCSPi\_IRQSTATUS** RXx\_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx\_FULL event will be asserted as soon as the MPU has not performed AFL + 1 reads into **MCSPi\_RXx**. The MPU must perform the right number of reads.

#### **23.4.4.5.2.4 RX0\_OVERFLOW**

The RX0\_OVERFLOW event is activated in slave mode in either transmit-and-receive or receive-only mode, when a channel is enabled and the **MCSPi\_RXx** register or FIFO is full when a new SPI word is received. The **MCSPi\_RXx** register is always overwritten with the new SPI word. If the FIFO is enabled data within the FIFO are overwritten, it must be considered as corrupted. The RX0\_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0\_OVERFLOW indicates an error (data loss) in slave mode.

The **MCSPi\_IRQSTATUS**[3] RX0\_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### **23.4.4.5.2.5 End Of Word Count**

The **MCSPi\_IRQSTATUS**[17] EOW event (end of word count) is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in the **MCSPi\_XFERLEVEL**[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as WCNT is not reloaded and channel re-enabled.

The **MCSPi\_IRQSTATUS**[17] EOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

#### **23.4.4.5.3 Interrupt-Driven Operation**

An interrupt enable bit in the SPIm.**MCSPi\_IRQENABLE** register can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the MPU must:

1. Read the SPIm.**MCSPi\_IRQSTATUS** register to identify which event occurred.

2. Read the [MCSPi\\_RXx](#) register that corresponds to the event to remove the source of an [RXx\\_FULL](#) event or write into the [MCSPi\\_TXx](#) register that corresponds to the event to remove the source of a [TXx\\_EMPTY](#) event. No action is required to remove the source of the [WKS](#) (wake-up), [TXx\\_UNDERFLOW](#), and [RX0\\_OVERFLOW](#) events.
3. Write 1 into the corresponding bit of the SPIm.[MCSPi\\_IRQSTATUS](#) register to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

#### 23.4.4.5.4 Polling

When the interrupt capability of an event is disabled in the SPIm.[MCSPi\\_IRQENABLE](#) register, the interrupt line is not asserted, but the status bits in the SPIm.[MCSPi\\_IRQSTATUS](#) register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- [RXx\\_FULL](#): To remove the source of the event, the MPU must read the corresponding [MCSPi\\_RXx](#) register.
- [TXx\\_EMPTY](#): To remove the source of the event, the MPU must write into the corresponding [MCSPi\\_TXx](#) register.
- [WKS](#) (wake-up), [TXx\\_UNDERFLOW](#), and [RX0\\_OVERFLOW](#): No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the SPIm.[MCSPi\\_IRQSTATUS](#) register to 1. This does not affect the interrupt line state.

#### 23.4.4.6 DMA Requests

The sDMA controller module manages DMA accesses. The sDMA controller advantage is to lower the MPU charge for data transfers.

Each MCSPi channel can issue DMA requests if they are enabled. There are two DMA request lines per MCSPi channel (one for read and one for write).

The DMA read request line is asserted when the MCSPi channel is enabled and new data is available in the receive register of the MCSPi channel. A DMA read request can be individually masked with the SPI1.[MCSPi\\_CHxCONF](#)[15] DMAR bit. The DMA read request line is deasserted on read completion of the [MCSPi\\_RXx](#) register of the MCSPi channel.

The DMA write request line is asserted when the MCSPi channel is enabled and the [MCSPi\\_TXx](#) register of the MCSPi channel is empty. A DMA write request can be individually masked with the SPI1.[MCSPi\\_CHxCONF](#)[14] DMAW bit. The DMA write request line is deasserted on load completion of the [MCSPi\\_TXx](#) register of the channel.

#### 23.4.4.7 Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity. The MCSPi is compliant with the idle and wake-up system handshake protocol.

##### 23.4.4.7.1 Normal Mode

In normal mode, internal SPI module clocks are automatically switched off (autogating) when there is no activity in slave or master mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The SPIm.[MCSPi\\_SYSCONFIG](#)[0] AUTOIDLE bit is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the MCSPi is not selected by the external master and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In master mode, an internal access occurs.
- In slave mode, an internal access occurs or the MCSPi is selected by the external master.

#### **23.4.4.7.2 Idle Mode**

At the PRCM module level, when all conditions are met to shut off the CORE\_48M\_FCLK or CORE\_L4\_ICLK output clocks (see [Chapter 3, Power, Reset, and Clock Management](#), for details), the PRCM module automatically launches a hardware handshake protocol to ensure that the MCSPi is ready to have its clocks switched off. Namely, the PRCM module asserts an idle request to the MCSPi.

Although this handshake is completely hardware-oriented and out of software control, the method in which the MCSPi module acknowledges the PRCM idle request is configurable through the MCSPi.SYSCONFIG[4:3] SIDLEMODE bit.

The settings of the SIDLEMODE bit and the related acknowledgment modes are:

- Force-idle mode (the SPIm.MCSPi\_SYSCONFIG[4:3] SIDLEMODE bit is set to 0x0): The MCSPi module acknowledges unconditionally the idle request from the PRCM module, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode the (SIDLEMODE bit is set to 0x1): The MCSPi module never acknowledges an idle request from the PRCM module and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
- Smart-idle mode (the SIDLEMODE bit set to 0x2): The MCSPi module acknowledges the idle request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for efficient system power management.

When configured in smart-idle mode, the MCSPi module also offers an additional granularity on the CORE\_48M\_FCLK and CORE\_L4\_ICLK gating. The SPIm.SYSCONFIG[9:8] CLOCKACTIVITY bit field determines which clock shuts down (the CORE\_48M\_FCLK, CORE\_L4\_ICLK, neither clock, or both clocks).

The CLOCKACTIVITY setting is used internally to MCSPi to determine on which part of the module the conditions to acknowledge the PRCM idle request are tested. For example, if CORE\_48M\_FCLK is not shut down on a PRCM idle request, MCSPi considers only CORE\_L4\_ICLK and the associated pending activities before acknowledging the request.

Some MCSPi features are associated with CORE\_L4\_ICLK and others with CORE\_48M\_FCLK. Using the CLOCKACTIVITY bit field along with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if MCSPi acknowledges an idle request.

The CLOCKACTIVITY settings and the associated features are:

- CLOCKACTIVITY set to 00: ICLK OFF and FCLK OFF, ICLK and FCLK are considered for generating the acknowledge. This setting also means that FCLK and ICLK are likely to be shut down on a PRCM idle request.
- CLOCKACTIVITY set to 01: ICLK ON and FCLK OFF, ICLK is not shut down on a PRCM idle request; only FCLK is concerned.
- CLOCKACTIVITY set to 10: ICLK OFF and FCLK ON, FCLK is not shut down on a PRCM idle request; only ICLK is concerned.
- CLOCKACTIVITY set to 11: ICLK ON and FCLK ON, none of the clocks are shut down. This means MCSPi can potentially acknowledge the idle request without checking the internal functions linked to its clocks.

**CAUTION**

The PRCM module does not have a hardware means of reading the CLOCKACTIVITY settings. Therefore, software must ensure consistent programming between CLOCKACTIVITY and the CORE\_48M\_FCLK and CORE\_L4\_ICLK control bits in the PRCM module. If the MCSPi is disabled in the CM\_FCLKEN and CM\_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its idle request, which is acknowledged regardless of the features associated with the MCSPi clocks. This can lead to unpredictable behavior.

**23.4.4.7.2.1 Wake-Up Event in Smart-Idle Mode**

The module wake-up feature is enabled when the SPIm.MCSPi\_SYSCONFIG[2] ENAWAKEUP and SPIm.MCSPi\_WAKEUPENABLE[0] WKEN bits are set. Wake-up capability is relevant only when the module is configured in slave mode.

The module generates an asynchronous wake-up request to the system power manager to switch back the interface clock and the functional clock. A wake-up is requested when channel 0 is enabled and an asynchronous selection occurs on the mcsxim.csx port associated with channel 0 (see the definition for the SPIm.MCSPi\_CHxCONF SPIENSLV bit field [where x = 0] in the register description table).

After the McSPi wake-up request, the system power manager must reactivate the interface clock:

- Before the beginning of the second SPI word serialization when McSPi is in slave transmit-only mode or in slave transmit-and-receive mode
- Before the end of the second received SPI word in slave receive-only mode. To avoid data loss, the first received SPI word must be read from the SPIm.MCSPi\_RXx register (where x = 0) before the completion of the second SPI word serialization.

Table 23-274 lists the supported cases in wake-up mode.

**Table 23-274. Smart-Idle Mode and Wake-Up Capabilities**

Mode	Interface Clock	SPI Clock Ref	Functionality	Wake-Up Event
Master	Must be maintained	Must be maintained	Full functionality, but the module does not generate a new interrupt or DMA request until the system exits wake-up mode	No wake-up event
Slave	Can be switched off	Can be switched off	An SPI word can be transmitted and/or received, but the module does not generate any new interrupts or DMA requests until the system exits wake-up mode.	The module asynchronously sends a wake-up request if an event on the mcsxim.csx port associated with channel 0 is detected.

In wake-up mode, the interrupt and DMA request lines are no longer asserted.

Any access to the module in wake-up mode generates an error as long as the interface clock is alive.

**23.4.4.7.2.2 Transitions From Smart-Idle Mode to Normal Mode**

The MCSPi detects the end of the wake period through the idle and wake-up hardware handshake protocol.

The interrupt status register (the SPIm.MCSPi\_IRQSTATUS[16] WKS bit) is updated with the event causing the wake-up; the wake-up event at the origin of the transition to the normal mode is converted to its corresponding interrupt when enabled by the SPIm.MCSPi\_IRQENABLE[16] WKE bit or the DMA request.

Interrupts and wake-up events have independent enable and disable controls, accessible through the SPIm.MCSPi\_IRQENABLE and SPIm.MCSPi\_WAKEUPENABLE registers. Software must ensure the overall consistency.

The interrupt status register SPIm.MCSPi\_IRQSTATUS is updated with the event causing the wake-up; the wake-up event at the origin of the transition to normal mode is converted to its corresponding interrupt request or DMA request. The module is fully operational.

#### **23.4.4.7.2.3 Force-Idle Mode**

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the SPIm.MCSPi\_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.

In force-idle mode, the MCSPi responds unconditionally to the idle request by deasserting unconditionally the interrupt and DMA request lines, if asserted. In addition, the wake-up capability is totally inhibited even if the SPIm.MCSPi\_SYSCONFIG[2] ENAWAKEUP and SPIm.MCSPi\_WAKEUPENABLE[0] WKEN bits are set.

The transition from normal mode to idle mode does not affect the interrupt event bits of the SPIm.MCSPi\_IRQSTATUS register.

In force-idle mode, because the module must be disabled, the interrupt and DMA request lines are likely deasserted. The interface clock and SPI clock provided to the MCSPi can be switched off.

An idle request during an SPI data transfer can lead to an unexpected and unpredictable result. Software must avoid such a request.

- The module exits force-idle mode through the idle and wake-up hardware handshake protocol. The module is fully operational. The interrupt and DMA request lines are optionally asserted one clock cycle later.

## 23.4.5 MCSPi Programming Guide

### 23.4.5.1 MCSPi Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the MCSPi module.

#### 23.4.5.1.1 Global Initialization

##### 23.4.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the I<sup>2</sup>C module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the I<sup>2</sup>C. See the *I<sup>2</sup>C Module Integration and Environment* sections for further information.

See [Section 23.4.3](#) for more information.

**Table 23-275. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	MCSPi_FCLK functional clock must be enabled. See <a href="#">Section 3.1.1.1.2</a> , <i>Module Level Clock Management</i> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
L4 Interconnect	For information about L4-PER interconnect configuration, see <a href="#">Section 13.3, L4 Interconnects</a> , in <a href="#">Chapter 13, Interconnect</a> .
sDMA	DMA configuration must be done to enable the module DMA channel requests. See <a href="#">Chapter 16, sDMA</a> .
MPU INTC	Cortex-A9 MPU, Cortex-M3 MPU, or DSP INTC must be configured to enable the interrupt request generation to the Cortex-A9 MPU or Cortex-M3 MPU, or in <a href="#">INTC</a> , in <a href="#">Chapter 5, DSP Subsystem</a> .

##### 23.4.5.1.1.2 MCSPi Global Initialization

###### 23.4.5.1.1.2.1 Main Sequence – MCSPi Global Initialization

This procedure initializes the MCSPi module after a POR or software reset.

**Table 23-276. MCSPi Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	SPIm.MCSPi_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is finished?	SPIm.MCSPi_SYSSTATUS[0] RESETDONE	=0x1

##### 23.4.5.1.2 Operational Mode Configuration

###### 23.4.5.1.2.1 MCSPi Operational Modes

The selection of the working mode is done with the SPIm.MCSPi\_CHxCONF register. [Table 23-277](#) through [Table 23-279](#) list the possible operating modes and their configurations.

**Table 23-277. MCSPi Receive Mode initialization**

Step	Register/Bit Field/Programming Model	Value
Set receive mode.	SPIm.MCSPi_CHxCONF[13:12] TRM	0x1
Set the word length.	SPIm.MCSPi_CHxCONF[11:7] WL	0x8
Clock initialization and channel enabling	SPIm.MCSPi_MODULCTRL[2] MS	0x0
	SPIm.MCSPi_CHxCTRL[0] EN	0x1
Channels activated low during active state	SPIm.MCSPi_CHxCONF[6] EPOL	0x1
Clock held high during active state	SPIm.MCSPi_CHxCONF[1] POL	0x0

**Table 23-277. MCSPi Receive Mode initialization (continued)**

Step	Register/Bit Field/Programming Model	Value
Data latched on odd-numbered edges of the SPI clock	SPIm.MCSPi_CHxCONF[0] PHA	0x0
Reset the status bits.	SPIm.MCSPi_IRQSTATUS	0x0

**Table 23-278. MCSPi Transmit Mode initialization**

Step	Register/Bit Field/Programming Model	Value
Set transmit mode.	SPIm.MCSPi_CHxCONF[13:12] TRM	0x2
Set the word length.	SPIm.MCSPi_CHxCONF[11:7] WL	0x8
Clock initialization and channel enabling	SPIm.MCSPi_MODULCTRL[2] MS SPIm.MCSPi_CHxCTRL[0] EN	0x0 0x1
Channels activated low during active state	SPIm.MCSPi_CHxCONF[6] EPOL	0x1
Clock held high during active state	SPIm.MCSPi_CHxCONF[1] POL	0x0
Data latched on odd-numbered edges of the SPI clock	SPIm.MCSPi_CHxCONF[0] PHA	0x0
Reset the status bits.	SPIm.MCSPi_IRQSTATUS	0x0

**Table 23-279. MCSPi Transmit and Receive Mode initialization**

Step	Register/Bit Field/Programming Model	Value
Set transmit and receive mode.	SPIm.MCSPi_CHxCONF[13:12] TRM	0x0
Set the word length.	SPIm.MCSPi_CHxCONF[11:7] WL	0x8
Clock Initialization and channel enabling	SPIm.MCSPi_MODULCTRL[2] MS SPIm.MCSPi_CHxCTRL[0] EN	0x0 0x1
Channels activated low during active state	SPIm.MCSPi_CHxCONF[6] EPOL	0x1
Clock held high during active state	SPIm.MCSPi_CHxCONF[1] POL	0x0
Data latched on odd-numbered edges of the SPI clock	SPIm.MCSPi_CHxCONF[0] PHA	0x0
Reset the status bits.	SPIm.MCSPi_IRQSTATUS	0x0

### 23.4.5.1.2.1.1 Common Transfer Procedures Without FIFO – Polling Method

#### 23.4.5.1.2.1.1.1 Receive-Only Procedure – Polling Method

Table 23-280 lists the receive-only procedure using the polling method. The MCSPi is acting as slave.

**Table 23-280. Receive-Only Procedure – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode	See Table 23-277	
Start the channel	SPIm.MCSPi_CHxCTRL[0] EN	0x1
Wait until receive register is full?	SPIm.MCSPi_RXx	=0x1
Stop the channel	SPIm.MCSPi_CHxCTRL[0] EN	0x0

#### 23.4.5.1.2.1.1.2 Receive-Only Procedure – Interrupt Method

Table 23-281 lists the receive-only procedure using the interrupt method. The MCSPi is acting as slave.

**Table 23-281. Receive-Only Procedure – Interrupt Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 23-277	
Start the channel.	SPIm.MCSPi_CHxCTRL[0] EN	0x1
Enable the interrupt for the receiver register.	SPIm.MCSPi_IRQENABLE[2] RX_FULL_ENABLE	0x1

**Table 23-281. Receive-Only Procedure – Interrupt Method (continued)**

Step	Register/Bit Field/Programming Model	Value
Read the status register.	SPIm.MCSPI_IRQSTATUS[2] RX_FULL	0x0
Disable the interrupt.	SPIm.MCSPI_IRQENABLE[2] RX_FULL_ENABLE	0x0
Stop the channel.	SPIm.MCSPI_CHXCTRL[0] EN	0x0
Read the receiver register.	SPIm.MCSPI_RXx	xxxx

#### 23.4.5.1.2.1.1.3 Transmit-Only Procedure - Polling Method

Table 23-282 lists the transmit-only procedure using the polling method. The MCSPI is acting as master.

**Table 23-282. Transmit-Only Procedure – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 23-278	
Start the channel.	SPIm.MCSPI_CHXCTRL[0] EN	0x1
Wait until end of transfer?	SPIm.MCSPI_CHXSTAT[2:1]	=0x2
Stop the channel.	SPIm.MCSPI_CHXCTRL[0] EN	0x0

#### 23.4.5.1.2.1.1.4 Transmit and Receive Procedure – Polling Method

Table 23-282 lists the transmit and receive procedure using the polling method. The MCSPI is acting as master and slave.

**Table 23-283. Transmit and Receive Procedure – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 23-279	
Start the channel.	SPIm.MCSPI_CHXCTRL[0] EN	0x1
Wait until transmit/receive word?	SPIm.MCSPI_CHXSTAT[2:0]	=0x3
Stop the channel.	SPIm.MCSPI_CHXCTRL[0] EN	0x0

#### 23.4.5.1.3 Common Transfer Procedures With FIFO – Polling Method

When using FIFO the MCSPI module can start the transfer only after the first write request is released by writing the MCSPI\_TXx register. The first write request can be managed by the IRQ routine or DMA handler. The end of transfer is more complex and depends on the transfer type. See Table 23-282 through Table 23-289.

##### 23.4.5.1.3.1 Receive-Only Procedure With Word Count – Polling Method

**Table 23-284. Receive-Only Procedure With Word Count – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 23-277	
Start the channel.	SPIm.MCSPI_CHXCTRL[0] EN	0x1
Wait until end of word count?	SPIm.MCSPI_IRQSTATUS[17] EOW	=0x1
Stop the channel.	SPIm.MCSPI_CHXCTRL[0] EN	0x0
Read from the receiver register.	SPIm.MCSPI_RXx	xxxx

##### 23.4.5.1.3.2 Transmit-Only Procedure With and Without Word Count – Polling Method

**Table 23-285. Transmit-Only Procedure Without Word Count – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See <a href="#">Table 23-278</a>	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Wait until end of word count?	SPIm.MCSPI_IRQSTATUS[17] EOW	=0x1
Wait until end of transfer?	SPIm.MCSPI_CHxSTAT[2] EOT SPIm.MCSPI_CHxSTAT[3] TXFFE	=0x1 =0x1
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0

### 23.4.5.1.3.3 Transmit-Only Procedure With and Without Word Count – Interrupt Method

**Table 23-286. Transmit-Only Procedure With Word Count – Interrupt Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See <a href="#">Table 23-278</a>	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Enable the interrupt for the transmit register.	SPIm.MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE	0x1
End of word count.	SPIm.MCSPI_IRQSTATUS[17] EOW	=0x1
End of transfer	SPIm.MCSPI_CHxSTAT[2] EOT SPIm.MCSPI_CHxSTAT[3] TXFFE	=0x1 =0x1
Clear the interrupt.	SPIm.MCSPI_IRQENABLE[17] EOW_ENABLE	=0x0
Disable the interrupt for the transmit register.	SPIm.MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE	0x0
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0

### 23.4.5.1.3.4 Transmit and Receive Procedure with Word Count – Polling Method

**Table 23-287. Transmit and Receive Procedure With Word Count – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See <a href="#">Table 23-279</a>	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Wait until end of word count?	SPIm.MCSPI_IRQSTATUS[17] EOW	=0x1
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0
Read from the receiver register.	SPIm.MCSPI_RXx	xxxx

### 23.4.5.1.3.5 Transmit and Receive Procedure with Word Count – Interrupt Method

**Table 23-288. Transmit and Receive Procedure With Word Count – Interrupt Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See <a href="#">Table 23-279</a>	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Enable the interrupt for the receiver register.	SPIm.MCSPI_IRQENABLE[2] RX_FULL_ENABLE	0x1
Enable the interrupt for the transmit register.	SPIm.MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE	0x1
End of word count?	SPIm.MCSPI_IRQSTATUS[17] EOW	=0x1
Clear the interrupt.	SPIm.MCSPI_IRQENABLE[17] EOW_ENABLE	=0x0
Disable the interrupt for the receiver register.	SPIm.MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE	0x0
Disable the interrupt for the transmit register.	SPIm.MCSPI_IRQENABLE[2] RX_FULL_ENABLE	0x0
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0

**Table 23-288. Transmit and Receive Procedure With Word Count – Interrupt Method (continued)**

Step	Register/Bit Field/Programming Model	Value
Read from the receiver register.	SPIm.MCSPI_RXx	xxxx

**23.4.5.1.3.6 Transmit and Receive Procedure Without Word Count – Polling Method****Table 23-289. Transmit and Receive Procedure Without Word Count – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See <a href="#">Table 23-279</a>	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Wait until end of transfer?	SPIm.MCSPI_CHxSTAT[2] EOT SPIm.MCSPI_CHxSTAT[3] TXFFE	=0x1 =0x1
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0
Read from the receiver register.	SPIm.MCSPI_RXx	xxxx

## 23.4.6 MCSPi Register Manual

### 23.4.6.1 MCSPi Instance Summary

**Table 23-290. MCSPi Instance Summary**

Module Name	Base Address	Size
MCSPi1	0x4809 8000	4KB
MCSPi2	0x4809 A000	4KB
MCSPi3	0x480B 8000	4KB
MCSPi4	0x480B A000	4KB

### 23.4.6.2 MCSPi Registers

#### 23.4.6.2.1 MCSPi Register Summary

Table 23-291 lists the MCSPi registers. Each register has a 32-bit width.

**Table 23-291. MCSPi Register Summary**

Register	Type	Offset Address	MCSPi1 L3 Physical Address	MCSPi2 L3 Physical Address	MCSPi3 L3 Physical Address	MCSPi4 L3 Physical Address
MCSPi_HL_REV	Rw	0x00	0x4809 8000	0x4809 A000	0x480B 8000	0x480B A000
MCSPi_HL_HWINFO	Rw	0x04	0x4809 8004	0x4809 A004	0x480B 8004	0x480B A004
MCSPi_HL_SYSCONFIG	Rw	0x10	0x4809 8010	0x4809 A010	0x480B 8010	0x480B A010
MCSPi_REVISION	R	0x100	0x4809 8100	0x4809 A100	0x480B 8100	0x480B A100
MCSPi_SYSCONFIG	RW	0x110	0x4809 8110	0x4809 A110	0x480B 8110	0x480B A110
MCSPi_SYSSTATUS	R	0x114	0x4809 8114	0x4809 A114	0x480B 8114	0x480B A114
MCSPi_IRQSTATUS	RW	0x118	0x4809 8118	0x4809 A118	0x480B 8118	0x480B A118

**Table 23-294. MCSPi\_HL\_HWINFO**

<b>Address Offset</b>	0x04	<b>Instance</b>	MCSPi1 MCSPi2 MCSPi3 MCSPi4
<b>Physical Address</b>	See Table 23-291		
<b>Description</b>	Information about the IP module's hardware configuration, that is, typically the module's HDL generics (if any). Actual field format and encoding is up to the module's designer to decide.		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD																								RETMODE	FFNBYTE	USEFIFO					

Bits	Field Name	Description	Type	Reset
31:7	RSVD	Reserved These bits are initialized to zero, and writes to them are ignored.	R	0x0000000
6	RETMODE	Retention Mode generic parameter This bit field indicates whether the retention mode is supported using the pin PIRFFRET. 0x0: Retention mode disabled 0x1: Retention mode enabled	R	RETMODE

Bits	Field Name	Description	Type	Reset
5:1	FFNBYTE	FIFO number of byte generic parameter This register defines the value of FFNBYTE generic parameter, only MSB bits from 8 down to 4 are taken into account. Read 0x1: FIFO 16 bytes depth Read 0x2: FIFO 32 bytes depth Read 0x4: FIFO 64 bytes depth Read 0x8: FIFO 128 bytes depth Read 0x10: FIFO 256 bytes depth	R	0x04
0	USEFIFO	Use of a FIFO enable: This bit field indicates if a FIFO is integrated within controller design with its management. Read 0x0: FIFO not implemented in design Read 0x1: FIFO and its management implemented in design with depth defined by FFNBYTE generic.	R	0

Multichannel Serial Port Interface (MCSPi)

- [MCSPi Register Summary: \[0\]](#)

**Table 23-300. MCSPi\_SYSCONFIG**

<b>Address Offset</b>	0x110		
<b>Physical Address</b>	See <a href="#">Table 23-291</a>	<b>Instance</b>	MCSPi1 MCSPi2 MCSPi3 MCSPi4
<b>Description</b>	This register allows controlling various parameters of the OCP interface.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CLOCKACTIVITY		RESERVED			SIDLEMODE		ENAWAKEUP	SOFTRESET	AUTOIDLE						

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Reads returns 0	RW	0x000000
9:8	CLOCKACTIVITY	Clocks activity during wake-up mode period 0x0: OCP and Functional clocks may be switched off. 0x1: OCP clock is maintained. Functional clock may be switched-off. 0x2: Functional clock is maintained. OCP clock may be switched-off. 0x3: OCP and Functional clocks are maintained.	RW	0x0
7:5	RESERVED	Reads returns 0	RW	0x0
4:3	SIDLEMODE	Power management 0x0: If an idle request is detected, the McSPi acknowledges it unconditionally and goes in Inactive mode. Interrupt, DMA requests and wake-up lines are unconditionally de-asserted and the module wake-up capability is deactivated even if the bit <a href="#">MCSPi_SYSCONFIG[EnaWakeUp]</a> is set. 0x1: If an idle request is detected, the request is ignored and the module does not switch to wake-up mode, and keeps on behaving normally. 0x2: If an idle request is detected, the module will switch to wake-up mode based on its internal activity, and the wake-up capability can be used if the bit <a href="#">MCSPi_SYSCONFIG[EnaWakeUp]</a> is set. 0x3: Reserved - do not use.	RW	0x2
2	ENAWAKEUP	Wake-up feature control 0x0: Wake-up capability is disabled 0x1: Wake-up capability is enabled	RW	1
1	SOFTRESET	Software reset. During reads it always returns 0. 0x0: (write) Normal mode 0x1: (write) Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware.	RW	0
0	AUTOIDLE	Internal OCP Clock gating strategy 0x0: OCP clock is free-running 0x1: Automatic OCP clock gating strategy is applied, based on the OCP interface activity	RW	1

<b>Address Offset</b>	0x124	<b>Instance</b>	MCSPi1 MCSPi2 MCSPi3 MCSPi4
<b>Physical Address</b>	See <a href="#">Table 23-291</a>		
<b>Description</b>	This register is used to check the correctness of the system interconnect either internally to peripheral bus, or externally to device IO pads, when the module is configured in system test (SYSTEST) mode.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																SSB	SPIENDIR	SPIDATDIR1	SPIDATDIR0	WAKD	SPICLK	SPIDAT_1	SPIDAT_0	SPIEN_3	SPIEN_2	SPIEN_1	SPIEN_0				

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Reads returns 0	RW	0x00000
11	SSB	Set status bit  0x0: No action. Writing 0 does not clear already set status bits; This bit must be cleared prior attempting to clear a status bit of the <MCSPi_IRQSTATUS> register.  0x1: Force to 1 all status bits of MCSPi_IRQSTATUS register. Writing 1 into this bit sets to 1 all status bits contained in the <MCSPi_IRQSTATUS> register.	RW	0
10	SPIENDIR	Set the direction of the SPIEN[3:0] lines and SPICLK line 0x0: output (as in master mode) 0x1: input (as in slave mode)	RW	0
9	SPIDATDIR1	Set the direction of the SPIDAT[1] 0x0: output 0x1: input	RW	0
8	SPIDATDIR0	Set the direction of the SPIDAT[0] 0x0: output 0x1: input	RW	0
7	WAKD	SWAKEUP output (signal data value of internal signal to system). The signal is driven high or low according to the value written into this register bit. 0x0: The pin is driven low. 0x1: The pin is driven high.	RW	0
6	SPICLK	SPICLK line (signal data value) If MCSPi_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the CLKSPi line (high or low), and a write into this bit has no effect. If MCSPi_SYST[SPIENDIR] = 0 (output mode direction), the CLKSPi line is driven high or low according to the value written into this register.	RW	0

Bits	Field Name	Description	Type	Reset
5	SPIDAT_1	SPIDAT[1] line (signal data value) If <a href="#">MCSPi_SYST[SPIDATDIR1]</a> = 0 (output mode direction), the SPIDAT[1] line is driven high or low according to the value written into this register. If <a href="#">MCSPi_SYST[SPIDATDIR1]</a> = 1 (input mode direction), this bit returns the value on the SPIDAT[1] line (high or low), and a write into this bit has no effect.	RW	0
4	SPIDAT_0	SPIDAT[0] line (signal data value) If <a href="#">MCSPi_SYST[SPIDATDIR0]</a> = 0 (output mode direction), the SPIDAT[0] line is driven high or low according to the value written into this register. If <a href="#">MCSPi_SYST[SPIDATDIR0]</a> = 1 (input mode direction), this bit returns the value on the SPIDAT[0] line (high or low), and a write into this bit has no effect.	RW	0
3	SPIEN_3	SPIEN[3] line (signal data value) If <a href="#">MCSPi_SYST[SPIENDIR]</a> = 0 (output mode direction), the SPIEN[3] line is driven high or low according to the value written into this register. If <a href="#">MCSPi_SYST[SPIENDIR]</a> = 1 (input mode direction), this bit returns the value on the SPIEN[3] line (high or low), and a write into this bit has no effect.	RW	0
2	SPIEN_2	SPIEN[2] line (signal data value) If <a href="#">MCSPi_SYST[SPIENDIR]</a> = 0 (output mode direction), the SPIEN[2] line is driven high or low according to the value written into this register. If <a href="#">MCSPi_SYST[SPIENDIR]</a> = 1 (input mode direction), this bit returns the value on the SPIEN[2] line (high or low), and a write into this bit has no effect.	RW	0
1	SPIEN_1	SPIEN[1] line (signal data value) If <a href="#">MCSPi_SYST[SPIENDIR]</a> = 0 (output mode direction), the SPIEN[1] line is driven high or low according to the value written into this register. If <a href="#">MCSPi_SYST[SPIENDIR]</a> = 1 (input mode direction), this bit returns the value on the SPIEN[1] line (high or low), and a write into this bit has no effect.	RW	0
0	SPIEN_0	SPIEN[0] line (signal data value) If <a href="#">MCSPi_SYST[SPIENDIR]</a> = 0 (output mode direction), the SPIEN[0] line is driven high or low according to the value written into this register. If <a href="#">MCSPi_SYST[SPIENDIR]</a> = 1 (input mode direction), this bit returns the value on the SPIEN[0] line (high or low), and a write into this bit has no effect.	RW	0

## 23.5 Multichannel Buffered Serial Port (McBSP)

This section introduces the Multi-Channel Buffered Serial Port.

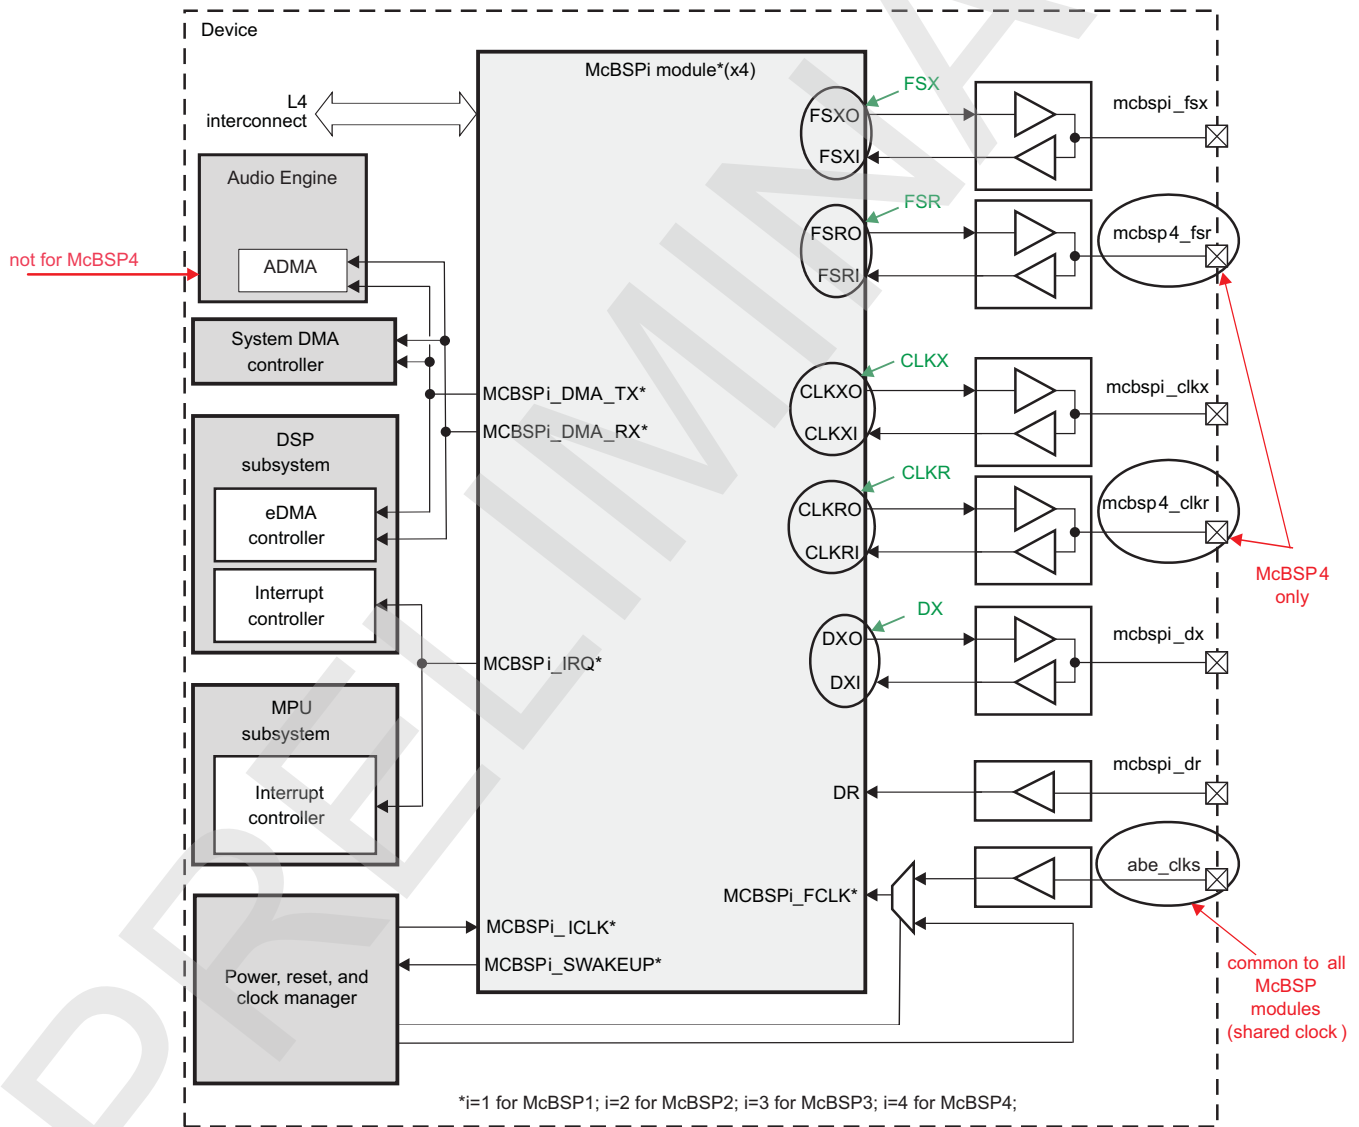

### 23.5.1 McBSP Overview

The multichannel buffered serial port (McBSP) provides a full-duplex direct serial interface between the device and other devices in a system such as other application chips (digital base band), audio and voice codec, etc. Because of its high level of versatility, it can accommodate a wide range of peripherals and clocked frame oriented protocols (for details, see [Section 23.5.1.1, McBSP Features](#)).

The device provides four instances of the McBSP module.

Figure 23-110 shows the McBSP overview in the device.

Figure 23-110. McBSP Highlight

mcbasp-001

#### 23.5.1.1 McBSP Features

The main features of the McBSP modules are:

- L4 interconnect slave interface supports:

- 32-bit data bus width
- 32-bit access supported
- 16-/8-bit access not supported
- 10-bit address bus width
- Burst mode not supported
- Write nonposted transaction mode supported
- 128 × 32-bit words (512 bytes) for each buffer for transmit/receive operations
- Transmit and receive DMA requests triggered with programmable FIFO thresholds
- Serial interface description
  - 6 pin configuration (McBSP 4 only)
  - 4 pin configuration (McBSP1,2, 3)
  - Full-duplex communication
  - Multichannel selection modes
    - Support to enable or block transfers in each of the channels
    - 128 channels for transmission and for reception
  - Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices:
    - Inter-IC sound (I2S) compliant devices
    - Pulse code modulation (PCM) devices
    - Time division multiplexed (TDM) bus devices

**CAUTION**

McBSP modules do not offer support for  $\mu$ -law and A-law companding, two partitions mode dynamic reassignment, AC'97, and SPI protocol.

- A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits
- Bit reordering (send/receive least significant bit [LSB])
- Clock and frame-synchronization generation support:
  - Independent clocking and framing for reception and for transmission up to 48 MHz
  - Support for external generation of clock signals and frame-synchronization (frame-sync) signals
  - A programmable sample rate generator for internal generation and control of clock signals and frame-sync signals
  - Programmable polarity for frame-sync pulses and for clock signals

**NOTE:**

- McBSP modules do not support features such as retransmit or re-receive of an erroneous frame or word.
- McBSP modules support dual phase frames to provide I2S fully compliant capabilities. But, this dual phase mode is limited at one channel (or word) for each phase instead of 128 channels max for single phase mode.

### 23.5.2 McBSP Environment

This section describes the intended functions for McBSP module from an environment point of view (that is, external connections). It presents the McBSP connectivity options, lists the possible interfaces, and details the protocol and data format used in each case.

#### 23.5.2.1 McBSP Functions

The device provides four instances of the McBSP module, called McBSP1, McBSP2, McBSP3 and McBSP4.

List of recommended usage (non exhaustive) per McBSP modules in the device:

- McBSP1: Digital baseband (DBB) Data
- McBSP2: Audio data
- McBSP3: Bluetooth voice data
- McBSP4: Midi data

[Table 23-326](#) describes the functions and the corresponding application fields.

**Table 23-326. Functions Description**

Function	Application field	Recommended McBSP module	Description
Control and Data	Digital Base Band (DBB) Data	McBSP1	Serial interface to transfer data
Audio Data	Audio Data without audio buffer and sidetone feature	McBSP2	Audio interface to transfer audio data with Inter-IC Sound codec (I2S)
	Midi Data	McBSP4	
Voice Data	Bluetooth Voice Data without sidetone feature	McBSP3	Voice interface to transfer voice data with Pulse Code Modulation codec (PCM)

#### 23.5.2.2 McBSP Signals Descriptions

The four McBSP modules consist of a data-flow path and a control path connected to external devices by a serial interface with 6 pins configuration (McBSP 4 only) or 4 pins configuration (McBSP1,2, 3).

For a McBSP module with 6 pins configuration, an internal loop back capability between Transmitter and Receiver clock signals, and both frame synchronisation signals enables using the McBSP module with 4 pins configuration. The related internal multiplexers are controlled through the System Control Module on the device (see [Section 23.5.3, McBSP Integration](#)).

**Table 23-327. Input/Output Description**

Pin Name	I/O	Description	Internal Signal Name	Reset Value	Control and Data	Audio Data	Voice Data
mcbasp_clks	I	External clock (shared by all McBSP modules)	CLKS	-	✓	✓	✓
abe_mcbspi_dr	I	Receive serial data	DR	-	✓	✓	✓
abe_mcbspi_dx	(I)O see Note below	Transmit serial data	DX	0	✓	✓	✓
abe_mcbspi_clkx	I/O <sup>(1)</sup>	Transmit clock <sup>(2)</sup>	CLKX	0	✓	✓	✓
abe_mcbspi_fsx	I/O <sup>(1)</sup>	Transmit frame synchronization <sup>(3)</sup>	FSX	0	✓	✓	✓
mcbasp4_dr	I	Receive serial data	DR	-	✓	✓	✓
mcbasp4_dx	(I)O see Note below	Transmit serial data	DX	0	✓	✓	✓
mcbasp4_clkx	I/O <sup>(1)</sup>	Transmit clock <sup>(2)</sup>	CLKX	0	✓	✓	✓
mcbasp4_fsx	I/O <sup>(1)</sup>	Transmit frame synchronization <sup>(3)</sup>	FSX	0	✓	✓	✓
mcbasp4_clkcr	I/O <sup>(1)</sup>	Receive clock <sup>(4)</sup>	CLKR	1	✓		
mcbasp4_fsr	I/O <sup>(1)</sup>	Receive frame synchronization <sup>(5)</sup>	FSR	0	✓		

<sup>(1)</sup> For details of the input/output selection, see [Section 23.5.2.3.1, McBSP Modes](#).

<sup>(2)</sup> This signal is also used as CLKR when it is configured as output.

<sup>(3)</sup> This signal is also used as FSR when it is configured as output.

<sup>(4)</sup> This signal is also used as CLKX when it is configured as input.

<sup>(5)</sup> This signal is also used as FSX when it is configured as input.

Legend: i= 1 to 3, I=Input, O=Output

- The mcbasp\_clks pin can be used to inject an external clock. This clock is used to generate control signals depending on the module internal configuration (see [Section 23.5.4.9, McBSP SRG](#)). The CLKS signal of the McBSP modules is linked to an external signal through the mcbasp\_clks pin, but the CLKS signal can also be linked to an internal clock provided by PRCM of the device. For more information, see [Section 23.5.3, McBSP Integration](#).
- Data are transmitted to external devices interfacing with McBSP modules via the mcbspi\_dx pin. Data from those devices are received on the mcbspi\_dr pin.

**NOTE:** The mcbspi\_dx pin is an input/output signal to use the McBSP module in half-duplex mode.

- Control information is communicated via the following pins: mcbspi\_clkx (transmit clock), mcbasp4\_clkcr (receive clock), mcbspi\_fsx (transmit frame-sync), and mcbasp4\_fsr (receive frame-sync).

#### CAUTION

External pins mcbasp4\_clkcr and mcbasp4\_fsr are connected to pads only for McBSP4 module; other McBSP modules don't have these connections. For these modules, CLKR and FSR signals sources are mcbspi\_clkx and mcbspi\_fsx pins, respectively. Consequently, there is a light restriction on other McBSP modules when used in full-duplex mode. Both reception and transmission use the same clock signal and the same frame synchronization signal.

### 23.5.2.3 McBSP Functions Description

#### 23.5.2.3.1 McBSP Modes

For all McBSP functions, McBSP modules can operate in master or slave mode. The difference between these modes is the definition of the source of McBSP clocks and McBSP frames synchronization:

- Master mode: McBSP module provides them to the external device
- Slave mode: McBSP module receives them from the external device

The choice between the two modes depends of technical data of the external device and the type of interface (protocols and data formats). For one McBSP module, there are four possible functions:

1. Transmit and receive master mode
2. Transmit and receive slave mode
3. Transmit master mode and receive slave mode
4. Transmit slave mode and receive master mode

**NOTE:** If the McBSP module has a serial interface with 4 pins configuration (McBSP1, 2, 3), only modes 1 or 2 are possible.

Figure 23-111 shows the connection between the McBSP4 module (6 pins configuration) and an external device in transmit master mode and receive slave mode.

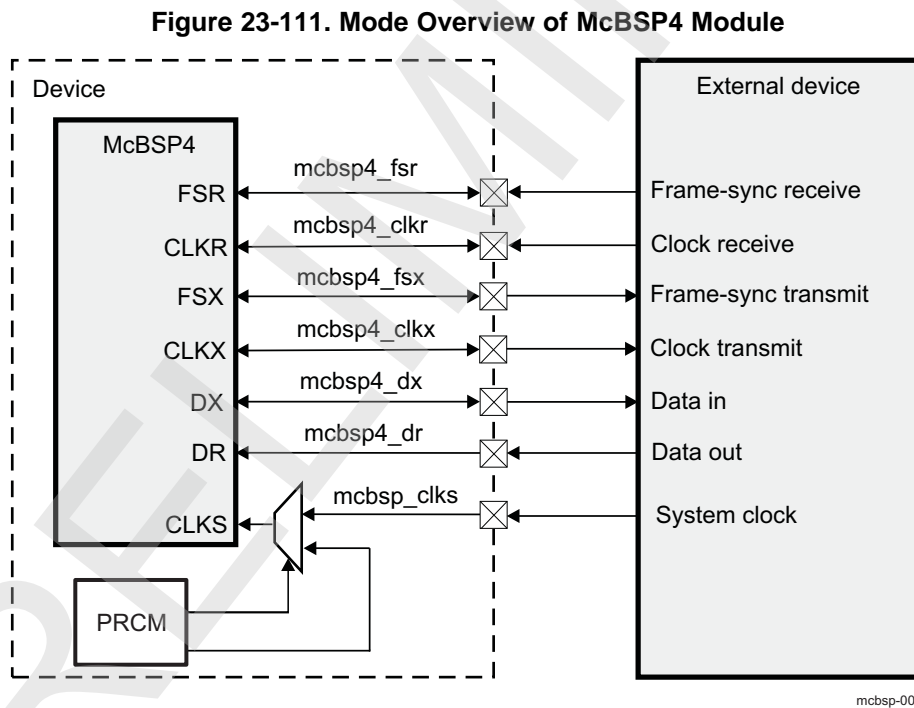

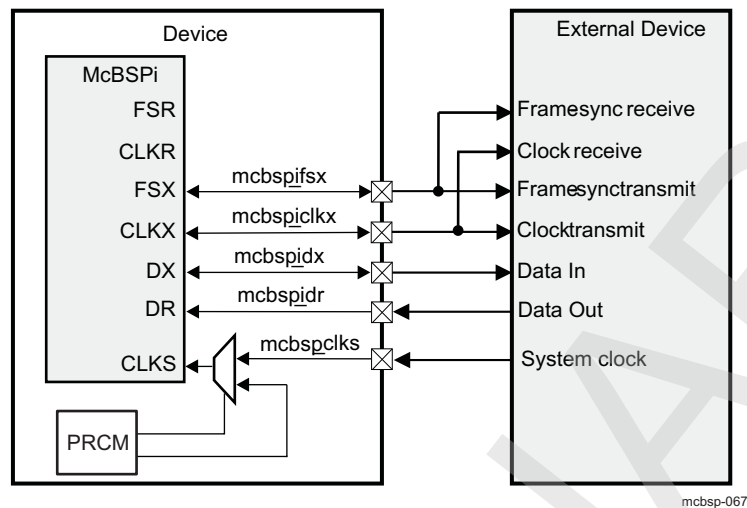

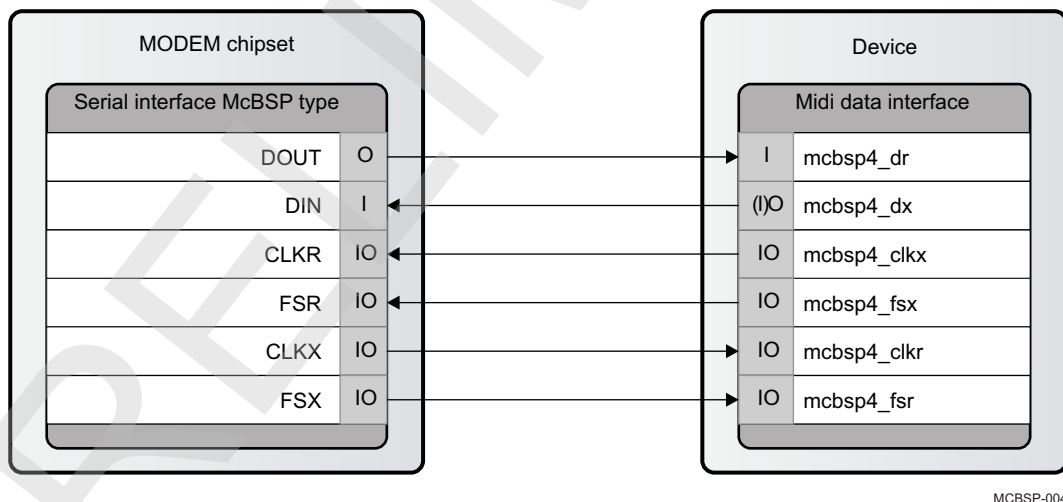

Figure 23-112 shows the connection between the McBSPi module, with i = 1, 2 or 3 (4 pins configuration) and an external device in transmit and receive master mode.

**Figure 23-112. Mode Overview of McBSPi Module**

### 23.5.2.3.2 McBSP Functions

#### 23.5.2.3.2.1 McBSP Function 1: Control and Data

In full-duplex mode (reception and transmission use independent clock signals and frame synchronization signals), the McBSP module can be used to exchange control and data with an external chipset, allowing the device to be interfaced with a modem device. Figure 23-113 shows typical connections between device and modem chipset to illustrate Midi data application.

**Figure 23-113. Midi Data Application**

In Figure 23-113, the McBSP4 module is configured in transmit master mode and in receive slave mode.

#### 23.5.2.3.2.2 McBSP Function 2: Audio Data

The McBSP module is connected to audio devices through the I2S interface. The I2S link serial interface is a TDM slot based serial interface that is used to transfer audio data. Those audio devices can be either AICs or other serially connected A/D and D/A devices.

Figure 23-114 shows typical connections between device and a typical device of analog audio interface to illustrate the audio data application. The typical device contains several audio analog inputs and outputs, as well as digital microphone inputs.

Figure 23-114. Audio Data Application

In Figure 23-114, the McBSP2 module is configured in transmit and receive master mode.

### 23.5.2.3.2.3 McBSP Function 3: Voice Data

The McBSP module is connected to a voice device through the PCM interface. The PCM link serial interface is a TDM slot based serial interface that is used to transfer voice data. The voice devices can be either modem chipsets, Bluetooth chipsets or others devices with voice data interface.

Figure 23-115 shows typical connections between device and Bluetooth chipset (TI BRF6300 or TI BRF6350) to illustrate voice data application.

Figure 23-115. Voice Data Application

In Figure 23-115, the McBSP3 module is configured in transmit and receive master mode.

### 23.5.2.4 McBSP Protocols and Data Formats

The McBSP module can use one of the three protocols with associated data formats:

- Serial protocol to exchange serial data
- Audio protocol to exchange the audio samples
- Voice protocol to exchange the voice samples

The McBSP modules offer the flexibility to modify the following parameters to adapt to the device features as described in the following subsections.

### 23.5.2.4.1 Words, Frames, and Phases Definitions

#### 23.5.2.4.1.1 Words or Channels

The data bits are transferred (transmission or reception) in a group called a serial word or channel. The number of bits in a word (length) is programmable via bits field (McBSPi.MCBSPLP\_RCR1\_REG[7:5] RWDLEN1 field and McBSPi.MCBSPLP\_RCR2\_REG[7:5] RWDLEN2 field, McBSPi.MCBSPLP\_XCR1\_REG[7:5] XWDLEN1 field and McBSPi.MCBSPLP\_XCR2\_REG[7:5] XWDLEN2 field) and can be 8, 12, 16, 20, 24 or 32 bits (see [Section 23.5.4.8.3, Clocking and Framing Data](#)). The McBSP module uses clock signals to control the time for each bit transfer. Data are sampled/driven on rising or falling edge of clock signals. This clock polarity is programmable via bits field of pin-control register (McBSPi.MCBSPLP\_PCR\_REG).

For more information, see [Section 23.5.4.8.4, Frame Phases \(Dual-Phase Frame I2S Support\)](#).

#### 23.5.2.4.1.2 Frames

One or more words (max 128) are transferred in a group called a frame. The McBSP module can transmit / receive a maximum of 128 words per frame, programmable via bits field of transmit and receive control registers (McBSPi.MCBSPLP\_XCR1\_REG/McBSPi.MCBSPLP\_XCR2\_REG and McBSPi.MCBSPLP\_RCR1\_REG/McBSPi.MCBSPLP\_RCR2\_REG). For more details, see [Section 23.5.4.8.3, Clocking and Framing Data](#).

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-synchronization signals to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP module begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP module receives/transmits the next frame, and so on. Frame-synchronization pulse is active high or low. This pulse polarity is programmable via bits field of pin-control register (McBSPi.MCBSPLP\_PCR\_REG).

Each frame transfer can be delayed by 0, 1, or 2 clock cycles, depending on the value of bits for transmit and receive control registers (McBSPi.MCBSPLP\_XCR2\_REG and McBSPi.MCBSPLP\_RCR2\_REG). For more information, see [Section 23.5.4.10.6.3, Preventing Unexpected Transmit Frame-sync Pulses](#) and [Section 23.5.4.10.3.3, Preventing Unexpected Receive Frame-sync Pulses](#).

#### 23.5.2.4.1.3 Phases

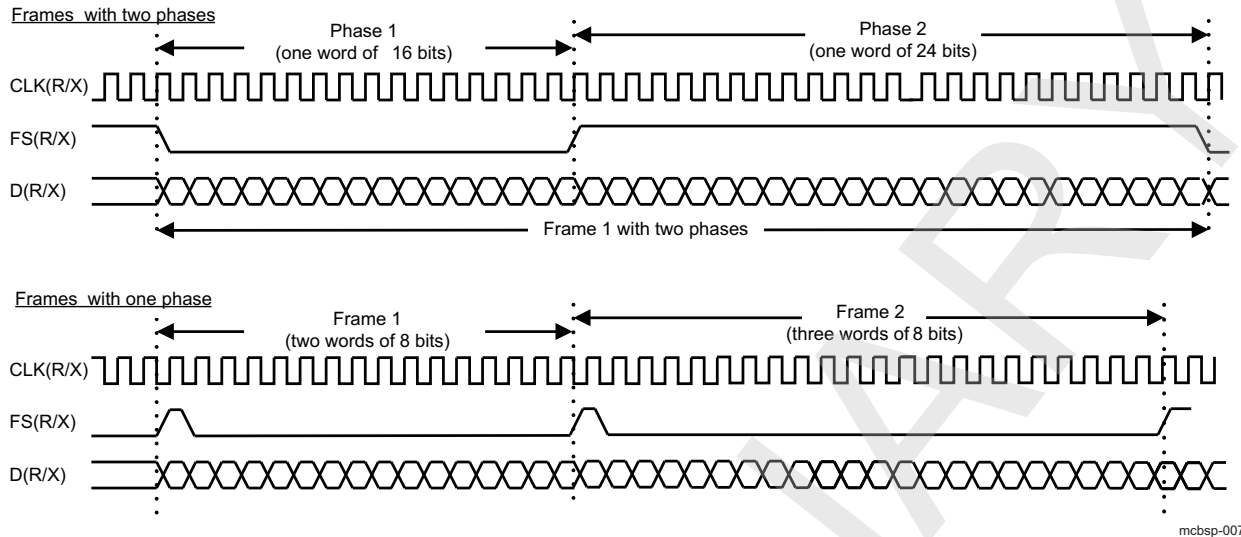

The McBSP module allows configuring each frame to contain one or two phases. The McBSP module supports dual phase frames to provide I2S fully compliant capabilities. These two phases represent left and right channels of audio stereo signals.

The limitation on dual phase frame is that the number of words per phase must be set to one for both first and second phase. But, the number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers.

For example, software may define a frame composed of a first phase with one 12-bit word and a second phase with one 16-bit word. This configuration allows the software to compose frames for custom applications. For more details, see [Section 23.5.4.8.4, Frame Phases \(Dual-Phase Frame I2S Support\)](#).

[Figure 23-116](#) shows signal activity for two possible reception/transmission scenarios.

Figure 23-116. McBSP Reception/Transmission Signal Activity

mcbasp-007

### 23.5.2.4.2 Serial Protocol and Data Formats

#### 23.5.2.4.2.1 Protocol

The serial protocol is used to send and receive control data without specific formats. This allows McBSP module to accommodate all serial devices and their protocols.

#### 23.5.2.4.2.2 Data Format

Figure 23-117 shows typical operation of the McBSP clock and frame sync signals. Serial clocks CLKR and CLKX define the boundaries between bits for receive and transmit, respectively. Similarly, frame-sync signals FSR and FSX define the beginning of an element and/or frame transfer. The McBSP module allows the configuration of the following parameters for data and frame synchronization:

- Polarity of FSR, FSX, CLKX, and CLKR
- The number of words per frame
- The number of bits per word
- Whether subsequent frame synchronization restarts the serial data stream or is ignored
- The data delay from frame synchronization to first data bit which can be 0-, 1-, or 2-bit delays

The configuration is independent for receive and transmit parts. For more details and configuration examples, see Section 23.5.4, *McBSP Functional Description* and Section 23.5.5, *McBSP Basic Programming Model*.

Figure 23-117. Serial Data Formats

mcbasp-009

### 23.5.2.4.3 Audio Protocol and Data Formats

#### 23.5.2.4.3.1 Protocol

The I2S protocol is used to send and receive audio data from 8 KHz up to 48 KHz sampling rate (frame-sync frequency), with 16 bits or 32 bits per words (Supported frequencies are 8, 11.025, 12, 16, 22.05, 24, 32, 44.1 and 48 KHz).

The frame-synchronization signal defines the frame length in the I2S protocol. Each frame consists of a fixed number of words. In dual-phase frame, the frame-synchronization signal is low for the left phase time slot and is high for the right phase time slot. In addition, the frame-synchronization signal is synchronous to the falling edge of the clock signal.

#### 23.5.2.4.3.2 Data Formats

The I2S protocol supports TDM, I2S, left justified, and right justified data formats.

Bits of each word (sample) are clocked using clock signal. For each word, MSB is first. LSBs are padded to 0 when the data length (8, 12, 16, 20, or 24 bits) is less than the sample word width (16 or 32 bits).

##### 23.5.2.4.3.2.1 TDM Data Format

Figure 23-118 shows that each frame of TDM data format is composed of four words (or channels).

**Figure 23-118. TDM Data Format; Word Width: 32 Bits; Data Length: 24 Bits**

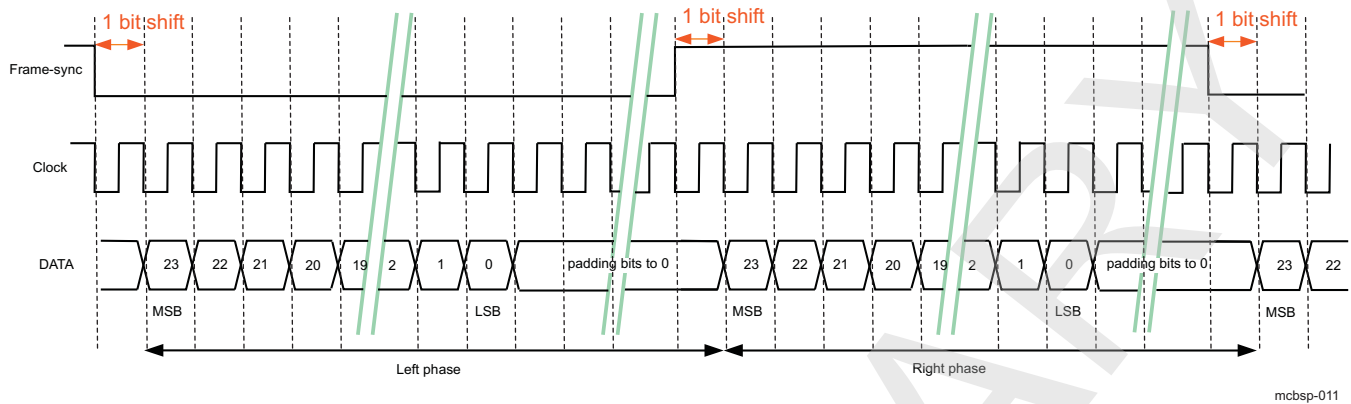

##### 23.5.2.4.3.2.2 I2S Data Format

Figure 23-119 shows an example with 24 bits data (MSB first) and 8 padding bits at '0'.

Figure 23-119. I2S Data Format; Word Width: 32 Bits; Data Length: 24 Bits

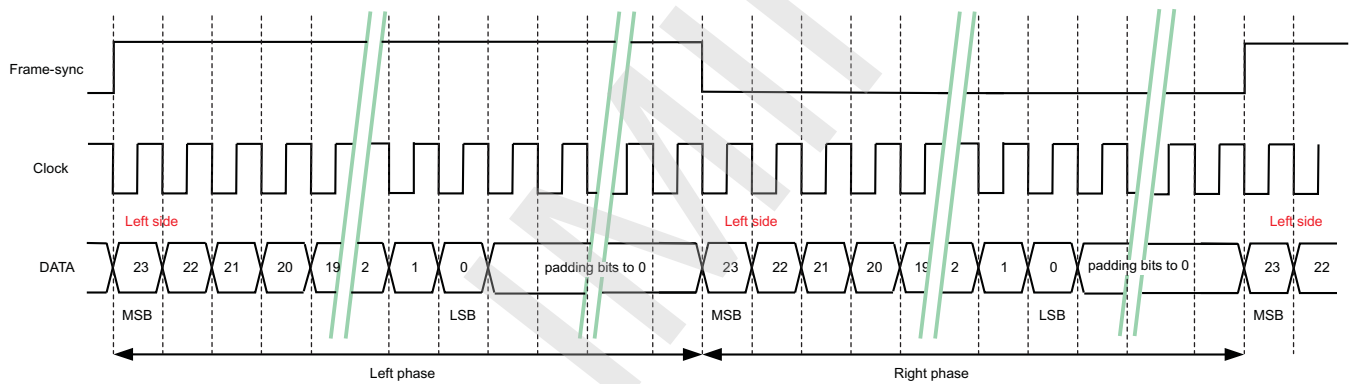

mcbasp-011

### 23.5.2.4.3.2.3 Left Justified Data Format

Figure 23-120 shows an example with 24 bits data (MSB first) and 8 padding bits at '0'.

Figure 23-120. Left Justified Data Format; Word Width: 32 Bits; Data Length: 24 Bits

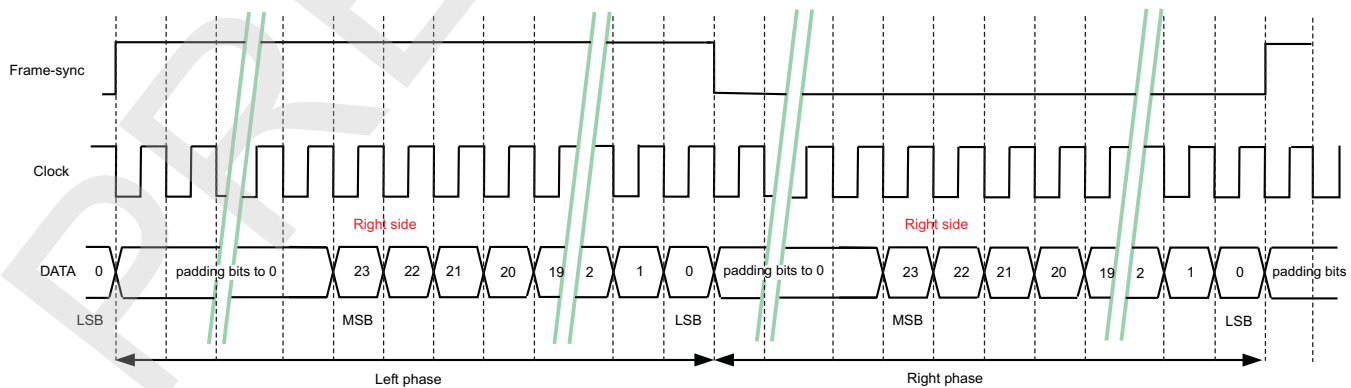

mcbasp-012

### 23.5.2.4.3.2.4 Right Justified Data Format

Figure 23-121 shows an example with 8 padding bits at '0' and 24 bits data (MSB first).

Figure 23-121. Right Justified Data Format; Word Width: 32 Bits; Data Length: 24 Bits

mcbasp-013

### 23.5.2.4.4 Voice Protocol and Data Formats

#### 23.5.2.4.4.1 Protocol

The PCM protocol is intended to transfer voice data at 8 kHz (default narrowband mode) or 16 kHz (wideband mode) sample rates (frame-sync frequency). PCM protocol can act as a slave or master, and is used by the Bluetooth interface and the modem generic interface. The frame-synchronization defines the frame length in the PCM protocol. Bits are clocked using PCM clock signal, with MSB first.

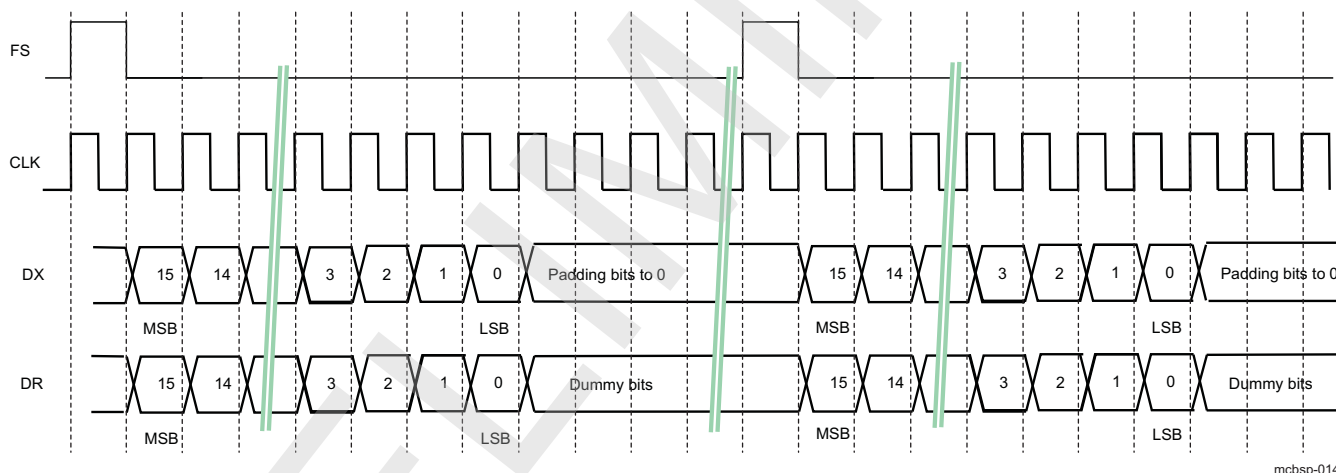

#### 23.5.2.4.4.2 Data Formats

Two modes are available for the PCM protocol: mode 1 and mode 2. For these both modes, it has two types of operations: Mono or stereo channels. The difference between PCM mode 1 and PCM mode 2 is in the way they use either the rising or the falling edge of clock signal, and the frame-synchronization polarity.

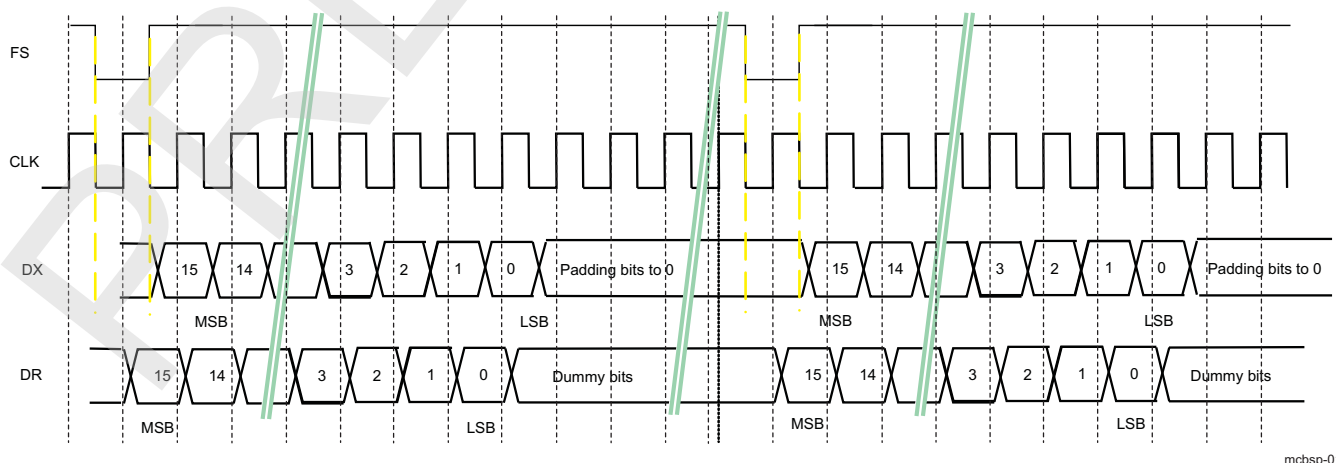

- PCM Mode 1: Input data is latched on the falling edge of the clock, and the transmitted data starts on the rising edge of the clock. Frame-synchronization pulse is active high.
- PCM Mode 2: Input data is latched on the falling edge of the clock, and the transmitted data starts on the falling edge of the clock. Frame-synchronization pulse is active low.

Figure 23-122 and Figure 23-123 shows an example of PCM protocol, mode 1 and mode 2, respectively, for a frame composed one word (width: 32 bits) with 16 bits data.

**Figure 23-122. PCM Protocol - Mode 1 Data Format**

**Figure 23-123. PCM Protocol - Mode 2 Data Format**

### 23.5.3 McBSP Integration

This section describes the McBSP modules integration in the device, including information about clocks, resets, and hardware requests.

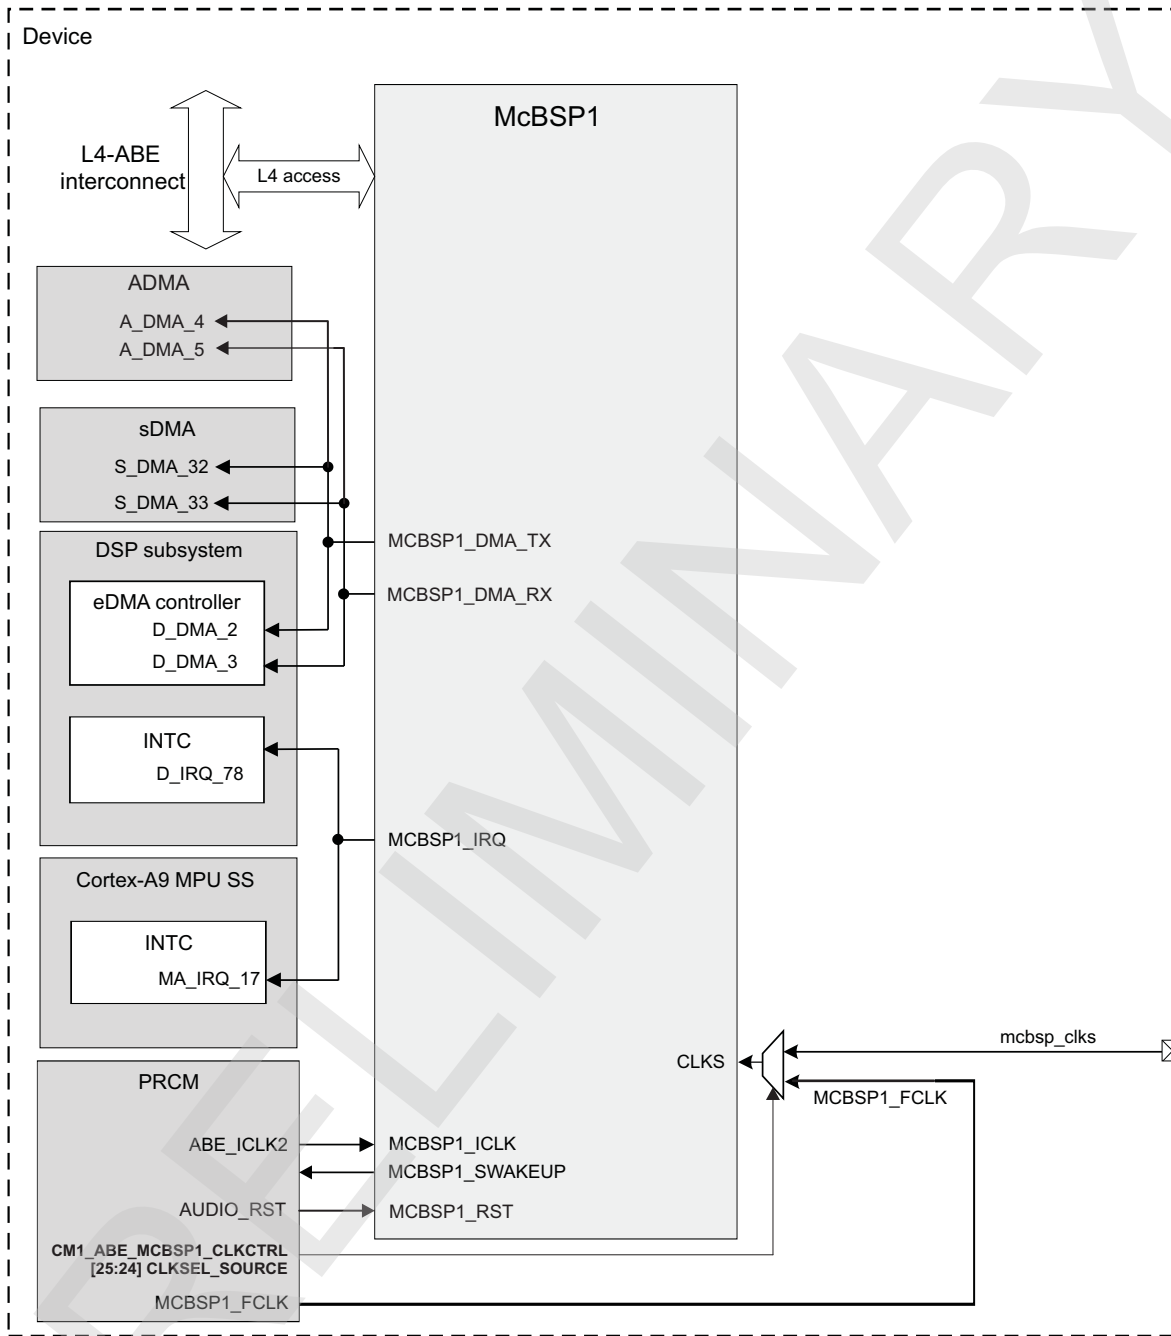

McBSP modules are divided into 2 families: McBSP modules that are gated in AUDIO power domain (McBSP1,2 and 3), and McBSP4 module which is gated in PER power domain.

[Figure 23-124](#) through [Figure 23-127](#) highlight the integration of the McBSP modules in the device including interrupt handlers, DMA requests, clock generators, and interconnections.

McBSP modules features:

- Wake-up request
- Two DMA requests
- One IRQ
- One functional clock
- One interface clock

Figure 23-124. McBSP1 Integration

mcbbsp-074

Figure 23-125. McBSP2 Integration

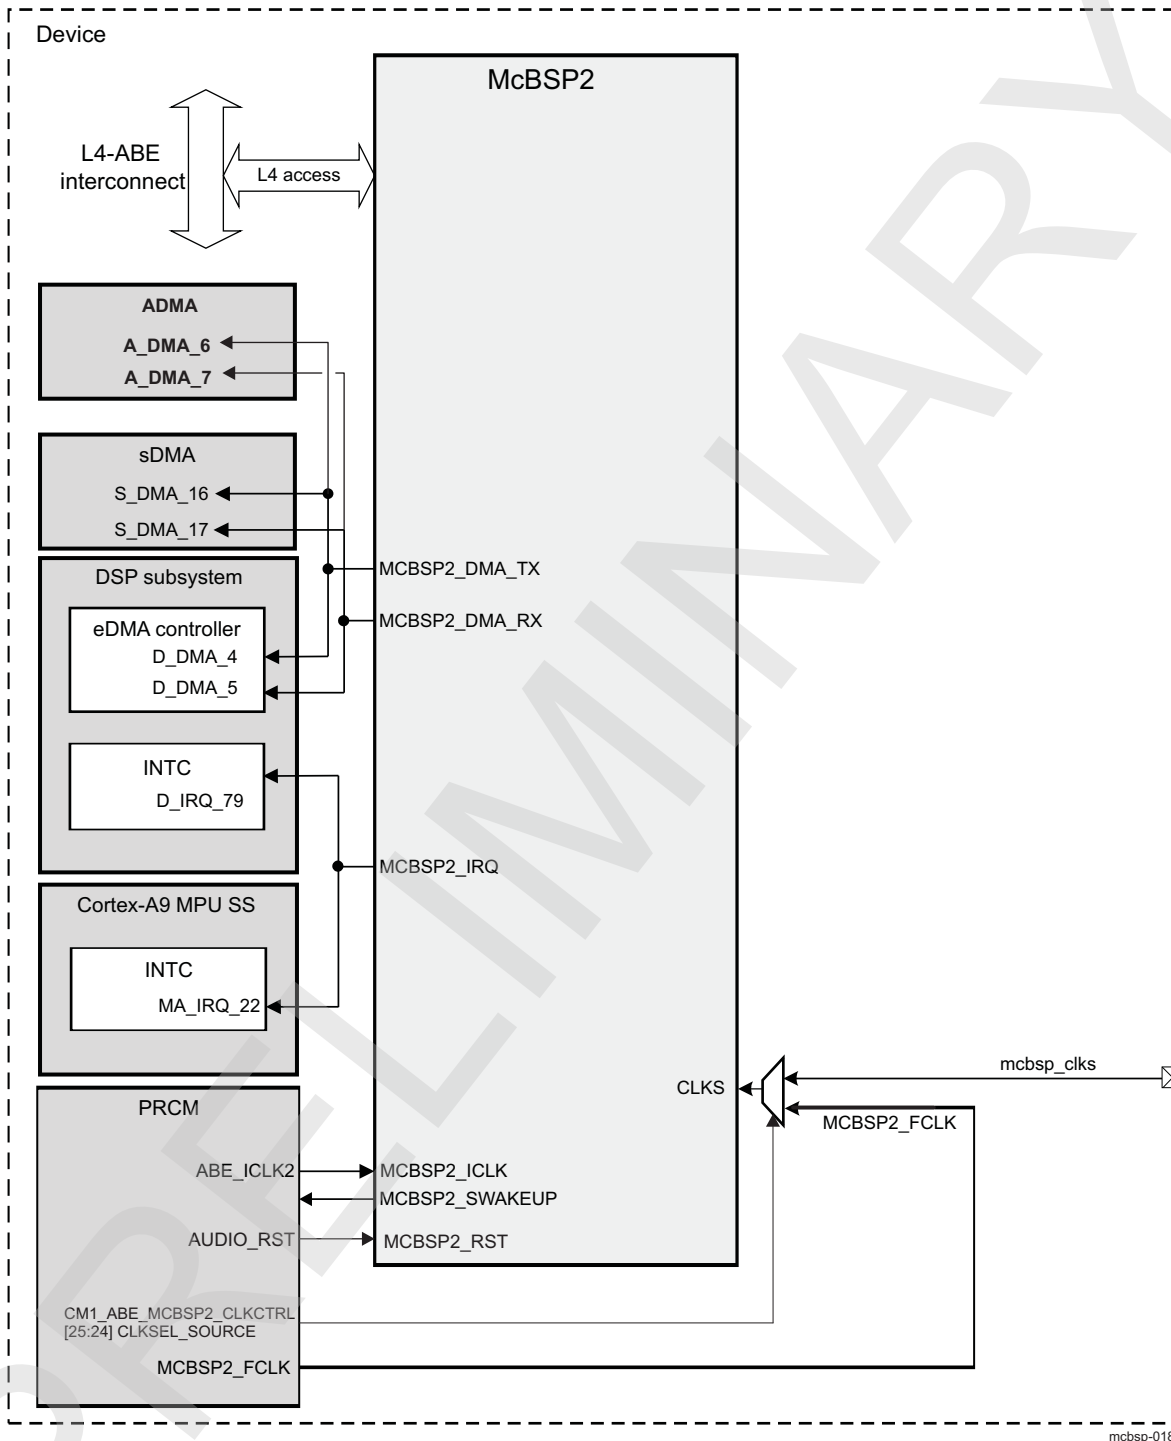

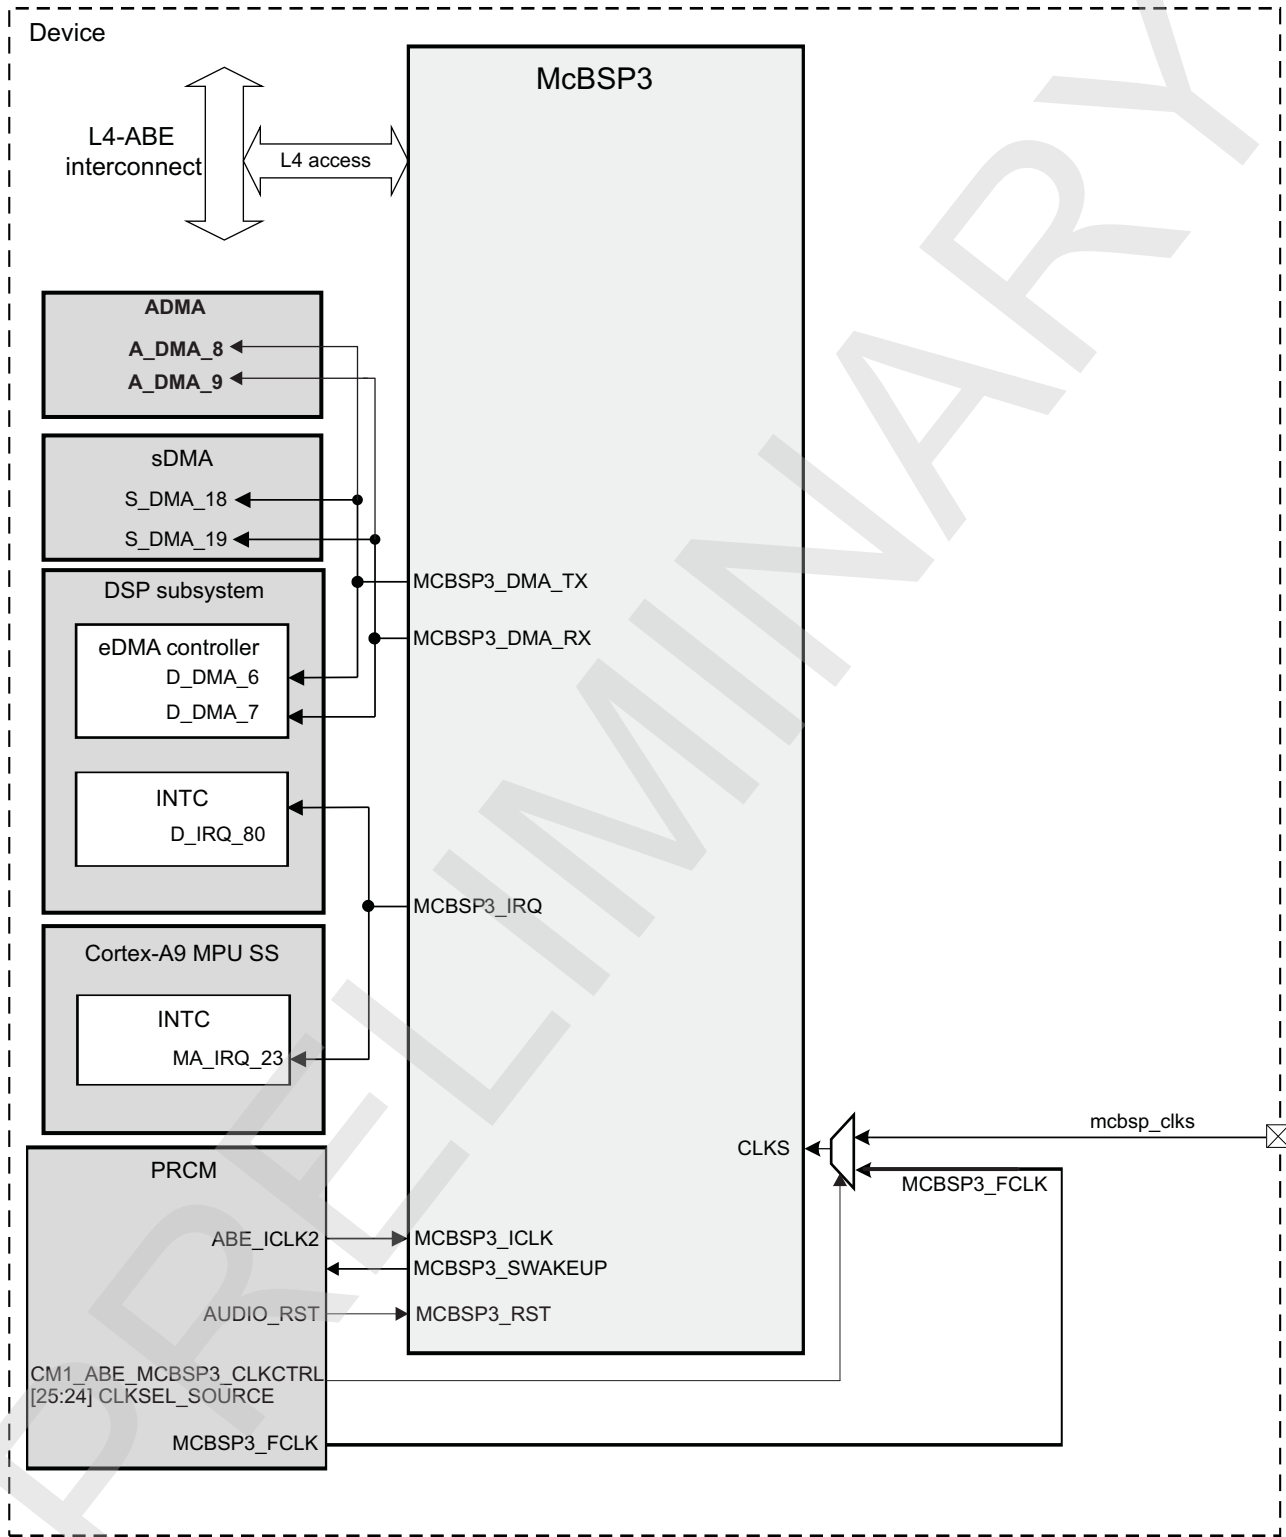

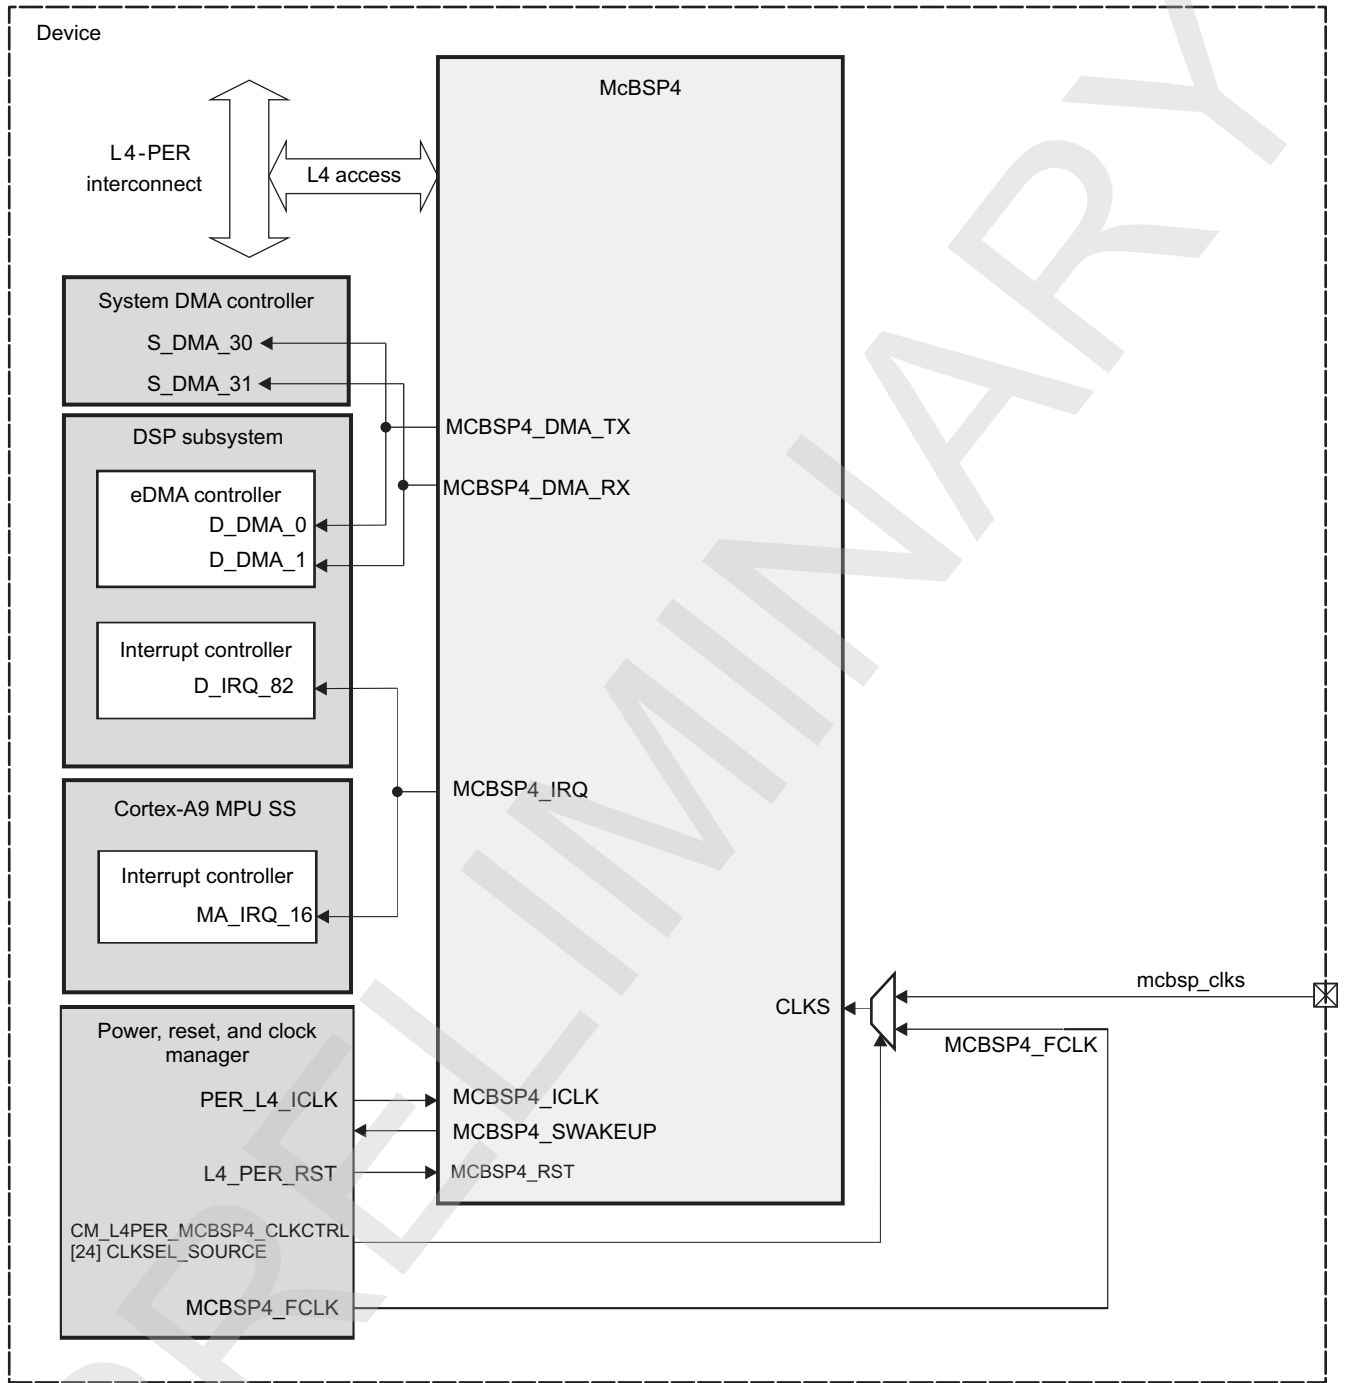

Figure 23-126. McBSP3 Integration

mcbbsp-019

Figure 23-127. McBSP4 Integration

mcbssp-017

**NOTE:** The selection between the FSX and FSR signals is made in the CONTROL\_MCBSP4[31] ALBCTRLRX\_FSX bit in the control module register. The selection between the CLKR and CLKX signals is made in the CONTROL\_MCBSP4[30] ALBCTRLRX\_CLKX bit in the control module register.

Table 23-328 through Table 23-330 summarize the integration of the module in the device.

**Table 23-328. Integration Attributes**

- About DMA source description, see [Section 23.5.4.7, DMA Requests](#).

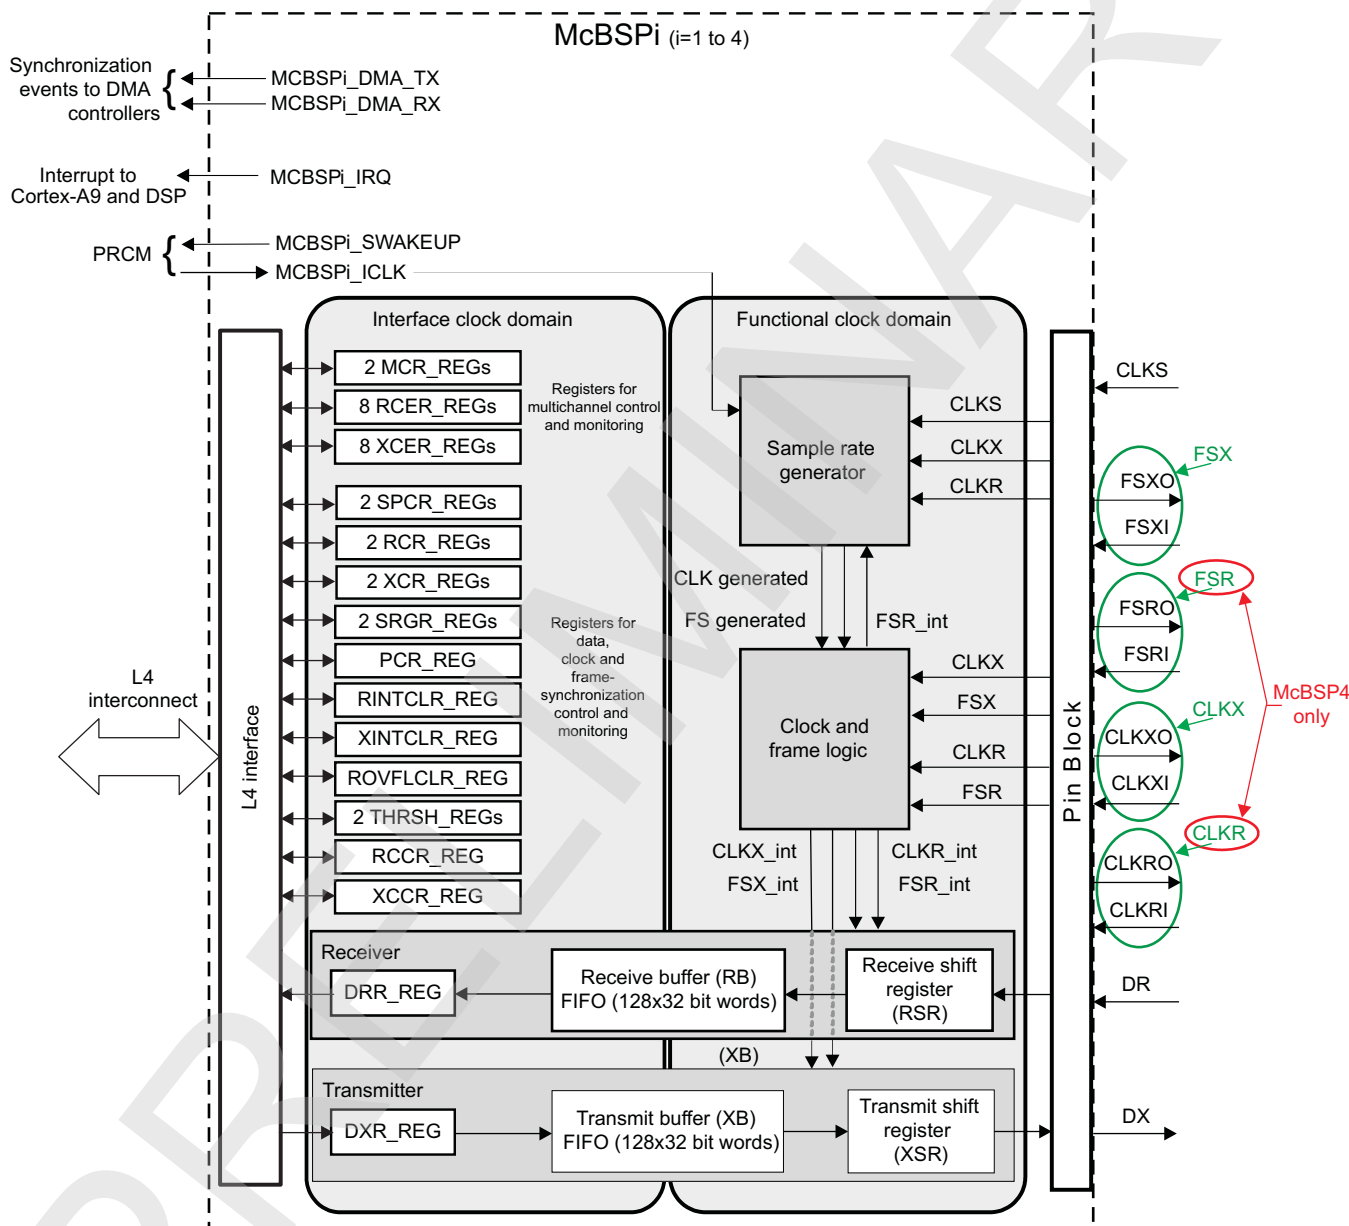

### 23.5.4 McBSP Functional Description

This section is a functional description of the McBSP module.

#### 23.5.4.1 Block Diagram

Figure 23-128 shows functional block diagram of the four instances of the McBSP modules.

Figure 23-128. McBSP iBlock Diagram

mcbasp-021

#### 23.5.4.2 Signal Source Control

The CLKX, DX, DR, FSX, FSR and CLKR signals sources are defined by the system control module. The control registers of the system control module are used to select these signals sources. For more information, see Chapter 18, Control Module.

### 23.5.4.3 McBSP Clock Configuration

#### 23.5.4.3.1 McBSP1 Clocks

The McBSP1 module is clocked by a functional clock (CLKS and CLKX) and an interface clock (MCBSP1\_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 23.5.4](#)). For McBSP1 module, the functional clock comes from the CLKS signal and the CLKX signal. The choice between these two clocks is defined by the SCLKME bit of the MCBSP1.MCBSPLP\_PCR\_REG[7] register and the CLKSM bit of the MCBSP1.MCBSPLP\_SRGR2\_REG[13] register.

The CLKS signal of the McBSP1 module is linked to an internal clock (MCBSP1\_FCLK) provided by PRCM. The CLKS signal can also be linked to an external signal through the mcbbsp\_clks pin of the device boundary.

---

**NOTE:** When the McBSP1 module does not require the functional clock anymore, the software can disable it at the PRCM level by configuring the MODULEMODE bit field to 0x0 (PRCM.CM1\_ABE\_MCBSP1\_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At PRCM level, when all the conditions to shut-off MCBSP1\_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

---

Only, the CLKX signal is connected by mcbbsp4\_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The MCBSP1\_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP1 L4 interface and McBSP1 configuration interface via the Cortex-A9 MPU/DSP shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 23.5.4.9, McBSP SRG](#)). Its source is the ABE\_ICLK2 signal.

---

**NOTE:** When the McBSP1 module does not require the interface clock anymore, the software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM1\_ABE\_MCBSP1\_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At PRCM level, when all the conditions to shut-off ABE\_ICLK2 clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power Reset and Clock Management](#).

---

#### 23.5.4.3.2 McBSP2 Clocks

The McBSP2 module is clocked by a functional clock (CLKS or CLKX) and an interface clock (MCBSP2\_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 23.5.4, McBSP Functional Description](#)). For McBSP2 module, the functional clock comes from the CLKS signal and CLKX signal. The choice between these two clocks is defined by the SCLKME bit of the MCBSP2.MCBSPLP\_PCR\_REG[7] register and the CLKSM bit of the MCBSP2.MCBSPLP\_SRGR2\_REG[13] register.

**NOTE:** When the McBSP2 module does not require the functional clock anymore, the software can disable it at the PRCM level by configuring the MODULEMODE bit field to 0x0 (PRCM.CM1\_ABE\_MCBSP2\_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At PRCM level, when all the conditions to shut-off MCBSP2\_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

Only, the CLKX signal is connected by mcbasp2\_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of the SRG.

- The MCBSP2\_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP2 L4 interface and McBSP2 configuration interface via the Cortex-A9 MPU/DSP shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 23.5.4.9, McBSP SRG](#)). Its source is either the ABE\_ICLK2 signal.

**NOTE:** When the McBSP2 module does not require the interface clock anymore, the software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM1\_ABE\_MCBSP2\_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At PRCM level, when all the conditions to shut-off ABE\_ICLK2 clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

### 23.5.4.3.3 McBSP3 Clocks

The McBSP3 module is clocked by a functional clock (CLKS or CLKX) and an interface clock (MCBSP3\_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 23.5.4, McBSP Functional Description](#)). For McBSP3 module, the functional clock comes from the CLKS signal and CLKX signal. The choice between these two clocks is defined by the SCLKME bit of the MCBSP3.MCBSPLP\_PCR\_REG[7] register and the CLKSM bit of the MCBSP3.MCBSPLP\_SRGR2\_REG[13] register.

**NOTE:** When the McBSP3 module does not require the functional clock anymore, the software can disable it at the PRCM level by configuring the MODULEMODE bit field to 0x0 (PRCM.CM1\_ABE\_MCBSP3\_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At PRCM level, when all the conditions to shut-off MCBSP3\_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

Only, the CLKX signal is connected by mcbasp3\_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The MCBSP3\_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP3 L4 interface and McBSP3 configuration interface via the Cortex-A9 MPU/DSP shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 23.5.4.9, McBSP SRG](#)). Its source is either the ABE\_ICLK2 signal.

**NOTE:** When the McBSP2 module does not require the interface clock anymore, the software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM1\_ABE\_MCBSP3\_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At PRCM level, when all the conditions to shut-off ABE\_ICLK2 clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

It is also possible to activate an autoidle mode for this clock (PRCM.CM\_AUTOIDLE\_PER[1] register AUTO\_MCBSP3 bit set to 1). In this case, McBSP3\_ICLK follows the AUDIO\_L4 clock domain behavior on the device. For more information, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

#### 23.5.4.3.4 McBSP4 Clocks

The McBSP4 module is clocked by a functional clock (CLKS, CLKX or CLKR) and an interface clock (MCBSP4\_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 23.5.4, McBSP Functional Description](#)). For McBSP4 module, the functional clock comes from the CLKS signal, CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP4.MCBSPLP\_PCR\_REG[7] register and the CLKSM bit of the MCBSP4.MCBSPLP\_SRGR2\_REG[13] register.

**NOTE:** When the McBSP4 module does not require the PRCM functional clock anymore, the software can disable it at the PRCM level by setting the MODULEMODE bit (PRCM.CM\_L4PER\_MCBSP4\_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At PRCM level, when all the conditions to shut-off MCBSP4\_FCLK clock are met the PRCM automatically launches a Hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

The CLKX and CLKR signals are connected either by mcbbsp4\_clkx or mcbbsp4\_clkr pads. These signals are used like functional clocks by the intermediary of the sample rate generator (SRG).

- The McBSP4\_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP4 L4 interface and McBSP4 configuration interface via the Cortex-A9 MPU/DSP shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 23.5.4.9, McBSP SRG](#)). Its source is the PER\_L4\_ICLK signal.

**NOTE:** When the McBSP4 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the MODULEMODE bit (PRCM.CM\_L4PER\_MCBSP4\_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At PRCM level, when all the conditions to shut-off PER\_L4\_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more details, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

#### 23.5.4.4 McBSP Software Reset

McBSP4 module belong to the PER domain and its reset signal is the L4\_PER\_RST from the PRCM module. The McBSP1, 2 and 3 modules belong to the AUDIO domain and their reset signal is the AUDIO\_RST from the PRCM module.

**Table 23-331. Software Reset Signals to All McBSP Modules**

Type	Bit Field	Register Source	Activation	Description
Software	SOFTRESET	MCBSPi.MCBSPLP_SYSCONFIG_REG[1]	Active high	McBSP global software reset
	RRST	MCBSPi.MCBSPLP_SPCR1_REG[0]	Active low	This resets and disables the receiver, including the RB
	XRST	MCBSPi.MCBSPLP_SPCR2_REG[0]		This resets and disables the transmitter, including the XB
	GRST	MCBSPi.MCBSPLP_SPCR2_REG[6]		SRG is reset
	FRST	MCBSPi.MCBSPLP_SPCR2_REG[7]	Frame-sync logic is reset. Frame-sync generated signal is not generated by the SRG	

See [Section 23.5.5.1, McBSP Initialization Procedure](#) for a complete description of the McBSP initialization procedure.

#### 23.5.4.5 McBSP Power Management

##### 23.5.4.5.1 McBSP Operating States

Two operating states are defined for all the McBSP modules:

- **ACTIVE** state: The module is running synchronously on the interface and functional clock, interrupts and DMA requests can be generated according to the configuration (register, master or slave mode, etc) and the external signals.
- **IDLE** state: As part of the system power management, the PRCM module can request the McBSP modules to enter IDLE state. Depending on the configured acknowledgment mode: Force Idle, No Idle and Smart Idle modes, a McBSP module will effectively enter IDLE state or not. As soon as a McBSP module enters IDLE state, it doesn't have anymore activities except those unrelated to clock activity (for example wakeup features) and its clocks are likely to be switched off at PRCM level.

**NOTE:** IDLE request and IDLE acknowledge are only internal signals, with no means to observe or to control. The signals generation and control is purely hardware (managed automatically by the PRCM and the McBSP module depending on the SIDLEMODE settings).

##### 23.5.4.5.2 McBSP Acknowledgment Modes

During initialization or configuration of the McBSP module, the software must configure how the McBSP module will answer an IDLE solicitation from the PRCM module (that is, the way idle acknowledge will be asserted following an idle request assertion).

Each McBSP module can be configured via the MCBSPi.MCBSPLP\_SYSCONFIG\_REG[4:3] SIDLEMODE field as one of the following acknowledgment modes:

- **Force Idle mode** (SIDLEMODE bit = 0x0): An idle request is acknowledged unconditionally, regardless of the internal state of the module. The McBSP module immediately enters Idle state (no activity), interface and PRCM functional clock can be stopped, no interrupts and DMA requests can be generated. In this mode, the McBSP module freezes all the internal activity when the PRCM clocks are switched off by the PRCM module, leading to a potential loss of data.

#### CAUTION

In Force Idle mode, the wake-up feature is inhibited.

**CAUTION**

If the McBSP functional part, transmitter or receiver, is running within this period of time (the functional clock source is not the PRCM functional clock), the internal state of the McBSP module will not be idle (FSM states, processes, etc.), and when the McBSP module exits from the Force Idle state unexpected behavior may happen in both receiver and transmitter. To avoid this, both receive and transmit parts, must be disabled by software prior to idle request assertion (all functional clock external sources must be disabled).

- No Idle mode (SIDLEMODE bit = 0x1): An idle request is never acknowledged, meaning it will prevent the PRCM from switching off its related clocks and from putting in a lower power state than the power domain it belongs to. The McBSP module never enters Idle state (is active).
- Smart Idle mode (SIDLEMODE bit = 0x2): Acknowledgement to an idle request is given based on the internal activity of the McBSP module. The McBSP module is in a waiting state, interface / functional clocks can be stopped, no interrupt can be generated, a wake-up signal can be generated according to the configuration (See [Section 23.5.4.5.4, Analysis of the Receiver Smart Idle Behavior](#)) and external signals.

**NOTE:** The value `MCBSPi.MCBSPLP_SYSCONFIG_REG[4:3]` SIDLEMODE field = 0x3 must not be used.

When configured in Smart Idle mode, McBSP module also offers an additional granularity on `MCBSPi_FCLK` and `MCBSPi_ICLK` gating. `MCBSPi.MCBSPLP_SYSCONFIG_REG[9:8]` CLOCKACTIVITY bit field is used to determine which clock will be shut down (`MCBSPi_FCLK`, `MCBSPi_ICLK`, none of them or both of them).

CLOCKACTIVITY setting is used in the McBSP module to determine on which part of the module the conditions to acknowledge the PRCM IDLE request will be tested. As an example, if `MCBSPi_FCLK` is said not to be shut down upon a PRCM IDLE request, this means McBSP module will only consider `MCBSPi_ICLK` and the associated pending activities before acknowledging the request.

**NOTE:** Some of McBSP features are associated to `MCBSPi_ICLK` and others to `MCBSPi_FCLK`. Using the CLOCKACTIVITY along with the Smart Idle mode ensures that the features associated with the clock that will remain active are always enabled, even if McBSP has acknowledged an IDLE request. For more information, see [Section 23.5.4.5.4, Analysis of the Receiver Smart Idle Behavior](#).

[Table 23-332](#) lists the value of the bit field and indicates if the interface (`MCBSPi_ICLK`) and PRCM functional (`MCBSPi_FCLK`) clocks can be switched-off or not when an Idle request is received by McBSP module.

**Table 23-332. State of Clocks When the Module is in Idle State**

CLOCKACTIVITY Value	Interface Clock (MCBSPi_ICLK)	PRCM Functional Clock
0b00	OFF	OFF
0b01	OFF	ON
0b10	ON	OFF
0b11	ON	ON

**NOTE:** OFF means this clock can be switched-off.

ON means this clock must be maintained during wake up period.

#### CAUTION

The PRCM module does not have any hardware mean to read CLOCKACTIVITY settings. It is thus software responsibility to ensure a consistent programming between McBSPi.MCBSPLP\_SYSCONFIG\_REG[9:8] CLOCKACTIVITY bit field and PRCM McBSPi\_FCLK and L4\_ICLK control bits (see Notes in previous Section 23.5.4.3, *McBSP Clock Configuration*). If McBSP module is disabled while CLOCKACTIVITY is set to 0x3, nothing prevents the PRCM module from asserting its IDLE request which will be acknowledged regardless of the features associated with the McBSP clocks. This may lead to unpredictable behaviors.

#### 23.5.4.5.3 Wake-Up Capability

When configured in Smart Idle mode, the sources for wake-up generation are a subset of the interrupt sources. The wake up sources are enabled by setting the McBSPi.MCBSPLP\_SYSCONFIG\_REG[2] ENAWAKEUP bit (wake up feature control):

- Set to '0', wake up capability is disabled
- Set to '1', wake up capability is enabled

The McBSPi\_SWAKEUP signal is the McBSP module asynchronous wake-up signal sent to the PRCM module when a wake-up generation is requested.

The wake up configurations are defined by setting the corresponding bits in the McBSPi.MCBSPLP\_WAKEUPEN\_REG register.

##### 23.5.4.5.3.1 Receive Wakeup

There are 4 receive possible wake up configurations:

- McBSPi.MCBSPLP\_WAKEUPEN\_REG[3] RRDYEN bit: The McBSP module asserts the McBSPi\_SWAKEUP request when the receive buffer reaches the high threshold value (RTHRESHOLD value + 1) of the McBSPi.MCBSPLP\_THRSH1\_REG register. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[3] RRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or DSP subsystems when exiting from idle mode (interrupt will be asserted once the McBSPi.MCBSPLP\_IRQSTATUS\_REG[3] RRDY bit changes from '0' to '1', indicating that received data is ready to be read).
- McBSPi.MCBSPLP\_WAKEUPEN\_REG[2] REOFEN bit: The McBSP module asserts the McBSPi\_SWAKEUP request at the end of the frame. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[2] REOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- McBSPi.MCBSPLP\_WAKEUPEN\_REG[1] RFSREN bit: The McBSP module sends a McBSPi\_SWAKEUP request to the PRCM module when a receive frame-sync pulse is detected while the McBSP module is in idle mode. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[1] RFSREN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- McBSPi.MCBSPLP\_WAKEUPEN\_REG[0] RSYNCERREN bit: The McBSP module asserts the McBSPi\_SWAKEUP request when an unexpected receive frame-sync pulse is detected. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[0] RSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or DSP subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.MCBSPLP\_IRQSTATUS\_REG[0] RSYNCERR bit changes from '0' to '1', indicating that a receive error occurred).

### 23.5.4.5.3.2 Transmit Wakeup

For transmit, there are also 5 possible wakeup configuration scenarios:

- McBSPi.MCBSPLP\_WAKEUPEN\_REG[14] XEMPTYEOFEN bit: The McBSP module asserts the McBSPi\_SWAKEUP request when a complete frame was transmitted and the transmit buffer is empty. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[14] XEMPTYEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or DSP subsystems when exiting from idle mode.
- McBSPi.MCBSPLP\_WAKEUPEN\_REG[10] XRDYEN bit: The McBSP module asserts the McBSPi\_SWAKEUP request when the transmit buffer reaches the high threshold value (XTHRESHOLD value + 1) of the McBSPi.MCBSPLP\_THRSH2\_REG register. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[10] XRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or DSP subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.MCBSPLP\_IRQSTATUS\_REG[10] XRDY bit changes from '0' to '1', indicating that transmit buffer data is ready to accept new data).
- McBSPi.MCBSPLP\_WAKEUPEN\_REG[9] XEOFEN bit: The McBSP module asserts the McBSPi\_SWAKEUP request at the end of the frame. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[9] XEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or DSP subsystems when exiting from idle mode.
- McBSPi.MCBSPLP\_WAKEUPEN\_REG[8] XFSXEN bit: The McBSP module sends a McBSPi\_SWAKEUP request when a transmit frame-sync pulse is detected while the module is in idle mode. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[8] XFSXEN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or DSP subsystems when exiting from idle mode.
- McBSPi.MCBSPLP\_WAKEUPEN\_REG[7] XSYNCERREN bit: The McBSP module asserts the McBSPi\_SWAKEUP request when an unexpected transmits frame-sync pulse is detected. If the McBSPi.MCBSPLP\_IRQENABLE\_REG[7] XSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi\_IRQ) request to the MPU or DSP subsystems when exiting from idle mode (interrupt will be asserted once the McBSPi.MCBSPLP\_IRQSTATUS\_REG[7] XSYNCERR bit changes from '0' to '1', indicating that a transmit error occurred).

### 23.5.4.5.3.3 Notes

When mcbbsp4\_fsr/mcbbsp\_i\_fsx pins is configured as an output, the FSR/FSX wakeup generation makes no sense (the module cannot be in Smart Idle mode).

Detection of RSYNCERR/XSYNCERR during idle mode can be used only when mcbbsp4\_fsr/mcbbsp\_i\_fsx pins is configured as an input and the remote system knows to assert such an error to trigger the wake up of the McBSP module.

The module does not implement interrupt request (IRQ) assertion when configured as (GPIO). Pins that can be used to accept input signals and/or send output signals but are not linked to specific uses; also a wake up capability in this mode is not available.

### 23.5.4.5.4 Analysis of the Receiver Smart Idle Behavior

The analysis of the power mode behavior is shown in [Table 23-333](#) :

In this table, the CLKRM bit is in the McBSPi.MCBSPLP\_PCR\_REG register on position 8, CLKXM bit in the McBSPi.MCBSPLP\_PCR\_REG[9] register, and CLOCKACTIVITY bit in the McBSPi.MCBSPLP\_SYSCONFIG\_REG[9:8] register.

The value X signifies that the bit value is not significant.

**Table 23-333. McBSP Smart Idle Mode Configuration Behavior**

CLKRM Bit	CLKXM Bit	McBSP Mode	Source of Functional Clock	CLOCKACTIVITY Bit	Behavior
0	0	Slave	outside	0bXX	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit buffer threshold synchronization (only when wake-up event is set on transmit threshold reached), regardless of the CLOCKACTIVITY settings or receive and transmit activity.
0	1	Transmit Master	MCBSPi_ICLK	0b0X	The McBSP will not acknowledge the Idle request unless: <ul style="list-style-type: none"> <li>The transmit part is disabled (XDISABLE) or under software reset (XRST).</li> <li>Both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST)</li> </ul> The idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable.
			CLKS	0bX0	
			MCBSPi_ICLK	0b1X	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).
			CLKS	0bX1	
			CLKR (outside)	0bXX	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.
			1	0	Receive master
CLKS	0bX0				
			MCBSPi_ICLK	0b1X	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).
			CLKS	0bX1	
			CLKX	0bXX	When CLKX is used as source (functional clock is provided from outside) then the module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.

**Table 23-333. McBSP Smart Idle Mode Configuration Behavior (continued)**

CLKRM Bit	CLKXM Bit	McBSP Mode	Source of Functional Clock	CLOCKACTIVITY Bit	Behavior
1	1	Transmit and Receive Master	MCBSPi_ICLK	0b0X	The McBSP will not acknowledge the idle request unless: Both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST) The idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable. Note that no wake-up event is available in this mode since the entire McBSP and remote device activity is frozen.
			CLKS	0bX0	
			MCBSPi_ICLK	0b1X	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).
			CLKS	0bX1	

**NOTE:** The RFSREN/XFSXEN mode is suitable for wakeup generation when both clocks (PRCM functional and interface) are switched off and `mcbasp4_fsr/mcbaspi_fsx` pins is configured as input. The frame-sync pulse is asynchronously detected during idle.

The RSYNCERREN/XSYNCERREN mode can be used to wakeup the McBSP module only by a remote module implementing such a feature, to trigger a wake up. This mode requires functional clock to be active.

#### 23.5.4.6 McBSP Interrupt Requests

Each of the four McBSP modules can generate one common interrupt (MCBSPi\_IRQ), shared between the Cortex-A9 MPU subsystem and DSP subsystem interrupt controllers.

An event can generate an interrupt request when the corresponding mask bit in the `McBSPi.MCBSPLP_IRQENABLE_REG` register is set to '1'.

Once an interrupt request is generated, the software must read the `McBSPi.MCBSPLP_IRQSTATUS_REG` register to check what event has caused the interrupt request generation, and acknowledge each processed event by writing a 1 to the corresponding bit in the `McBSPi.MCBSPLP_IRQSTATUS_REG` register.

#### 23.5.4.7 McBSP DMA Requests

The DMA requests are shared between the DSP subsystem DMA controller (eDMA), system DMA controller (sDMA) and Audio Engine DMA controller (ADMA). Each of the four McBSP modules can generate two DMA events:

- `MCBSPi_DMA_TX` : McBSPi module transmit DMA request
- `MCBSPi_DMA_RX` : McBSPi module receive DMA request

Table 23-330 summarizes the DMA events with the mapping on both DMA controllers.

The receive and transmit DMA requests can be individually disabled by setting the `McBSPi.MCBSPLP_RCCR_REG[3]` RDMAEN, `McBSPi.MCBSPLP_XCCR_REG[3]` XDMAEN bits to 0. When disabling the DMA, the DMA request line is de-asserted even if a DMA transfer is pending and the DMA state-machine is not reset.

See Section 23.5.4.11, *McBSP DMA Configuration* for more details.

### 23.5.4.8 McBSP Data Transfer Process

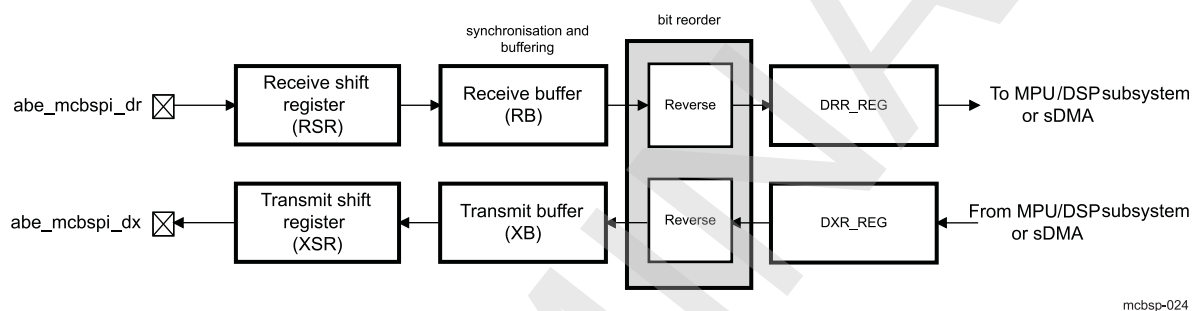

For McBSP modules, receive and transmit operations are triple-buffered (512 bytes buffers organized in 32-bit words are used).

All registers of McBSP data transfer paths are 32-bits wide. Figure 23-129 shows the McBSP data transfer paths.

**CAUTION**

The McBSP registers (DRR\_REG and DXR\_REG) are limited to 32-bit data accesses (L4 Interconnect). 16-bit and 8-bit is not allowed and can corrupt register content.

**Figure 23-129. McBSP Data Transfer Paths**

#### 23.5.4.8.1 Data Transfer Process for 8- / 12- / 16- / 20- / 24- / 32-bits Long Words

**CAUTION**

For each data word length, one data occupies one 32-bit buffer word.

Receive data arrives on the mcbspi\_dr pin and is shifted into the receive shift register (RSR). When a full word (depending on the data length configuration) is received, the content of the shift register is copied into the receive buffer (RB) if it is not full. When the RB threshold is reached the McBSP module asserts DMA or interrupt request and the RB content is then transferred (the sDMA or the eDMA controller reads the data receive register McBSPi.MCBSPLP\_DRR\_REG).

Transmit data is written by the MPU subsystem, the DSP subsystem or the DMA controller to data transmit register (McBSPi.MCBSPLP\_DXR\_REG) using the McBSPi.MCBSPLP\_SPCR2\_REG[1] XRDY bit enable input (when a byte is not enabled, the byte value in the memory will contain the previous written value). If there is no previous data in transmit shift register (XSR), the value from the transmit buffer (XB) is copied to XSR; otherwise, the content is copied to the XSR when the last bit of the previous data is shifted out on the mcbspi\_dx pin.

#### 23.5.4.8.2 Bit Reordering (Option to Transfer LSB First)

Generally, the McBSP module transmits or receives all data with the MSB first. However, some data protocols require the LSB to be transferred first.

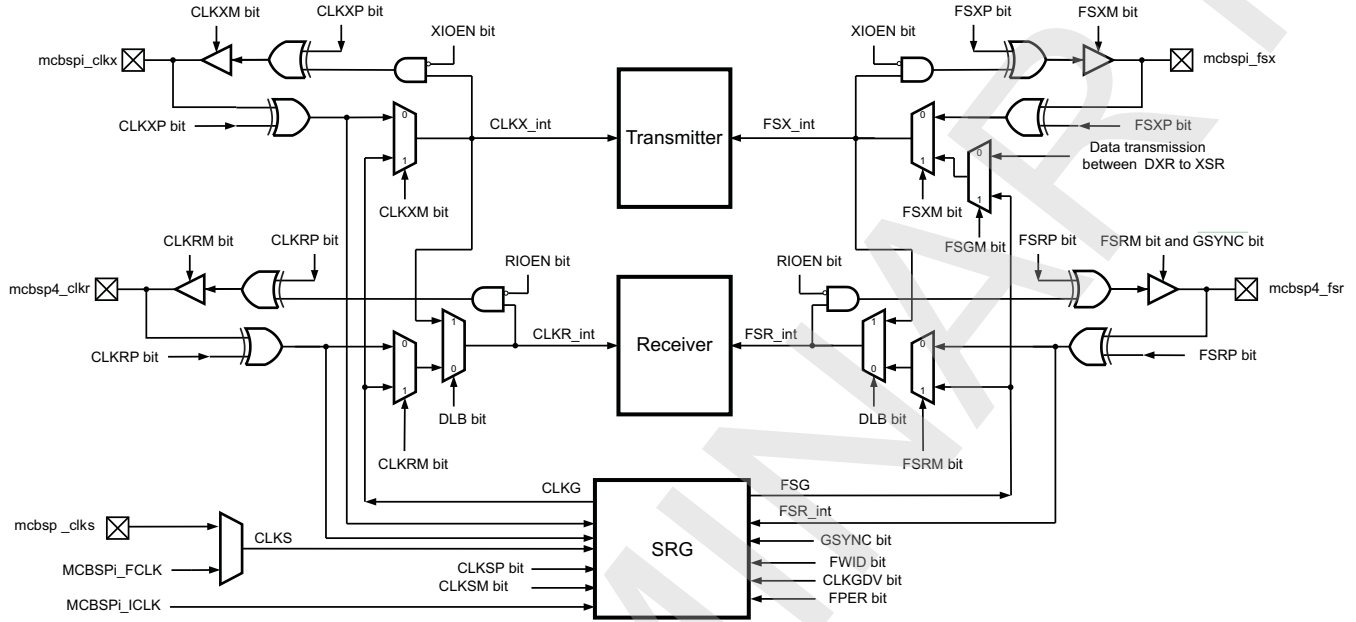

If you set McBSPi.MCBSPLP\_XCR2\_REG[4:3] XREVERSE=0b01, the bit ordering of the data words is reversed (LSB first) before being sent to the serial port. If you set McBSPi.MCBSPLP\_RCR2\_REG[4:3] RREVERSE=0b01, the bit ordering of the data words is reversed during reception (LSB first).

This feature is available for all the data formats from 8 up to 32-bit data length.

23.5.4.8.3 Clocking and Framing Data

This section explains basic concepts and terminology important for understanding how McBSP data transfers are timed and delimited.

Figure 23-130. Conceptual Block Diagram for Clock and Frame Generation

mcbasp-025

23.5.4.8.3.1 Clocking

Data is shifted one bit at a time from the mcbspi\_dr pin to the RSRs or from the XSRs to the mcbspi\_dx pin. The time for each bit transfer is controlled by the rising or falling edge of a clock signal.

The receive clock signal (CLKR\_int) controls bit transfers from the mcbspi\_dr pin to the RSRs. The transmit clock signal (CLKX\_int) controls bit transfers from the XSRs to the mcbspi\_dx pin. CLKR\_int or CLKX\_int signals can be derived from a pin at the boundary of the McBSP module (mcbasp4\_clkr and mcbspi\_clkx respectively) or derived from inside the McBSP module (see Figure 23-130). The clocks source is selected by programming the McBSPi.MCBSPLP\_PCR\_REG[9] CLKXM bit and the McBSPi.MCBSPLP\_PCR\_REG[8] CLKRM bit respectively.

When the McBSPi.MCBSPLP\_PCR\_REG[9] CLKXM bit (transmitter clock mode) is set to:

- '0', CLKX\_int is driven by an external clock and mcbspi\_clkx is an input pin.
- '1', CLKX\_int is driven by the internal sample rate generator and mcbspi\_clkx is an output pin.

For the McBSPi.MCBSPLP\_PCR\_REG[8] CLKRM bit (receiver clock mode), see Table 23-334.

Table 23-334. Receiver Clock Mode

Value	Digital loop back mode	mcbasp4_clkr pin	Description
0x0	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =0	input	CLKR_int is driven by an external clock
	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =1	High-impedance	CLKR_int is driven by CLKX_int. The CLKX_int is derived based on the CLKXM value.
0x1	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =0	output	CLKR_int is driven by the internal sample rate generator
	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =1	output	CLKR_int is driven by CLKX_int. The CLKX_int is derived based on the CLKXM value.

The polarities of CLKR and CLKX signals are configured in McBSPi.MCBSPLP\_PCR\_REG register.

The McBSPi.MCBSPLP\_PCR\_REG[1] CLKXP defines the transmit clock polarity:

- When set to 0, transmit data driven on rising edge of CLKX signal
- When set to 1, transmit data driven on falling edge of CLKX signal

The McBSPi.MCBSPLP\_PCR\_REG[0] CLKRP defines the receive clock polarity:

- When set to 0, receive data sampled on falling edge of CLKX signal
- When set to 1, transmit data sampled on rising edge of CLKX signal

Figure 23-131 gives an example where the clock signal controls the timing of each bit transfer on the pin.

**Figure 23-131. Clock Signal Control of Bit Transfer Timing**

**NOTE:** The McBSP module is constrained to operate at an internal functional frequency of up to L4 interface frequency divided by 2. When driving CLKX or CLKR at the pin, choose an appropriate input clock frequency. When using the internal sample rate generator for CLKX/CLKR/CLKS, choose an appropriate input clock frequency (up to L4 interface frequency) and divide down value by programming the McBSPi.MCBSPLP\_SRGR1\_REG[7:0] CLKGDV bit field.

### 23.5.4.8.3.2 Serial Words

Bits traveling between a shift register (RSR or XSR) and a data pin (mcbspi\_dr or mcbspi\_dx) are transferred in a group called a serial word. The software defines how many bits are in a word by programming:

- For the receiver: the McBSPi.MCBSPLP\_RCR1\_REG[7:5] RWDLEN1 field and the McBSPi.MCBSPLP\_RCR2\_REG[7:5] RWDLEN2 field.
- For the transmitter: the McBSPi.MCBSPLP\_XCR1\_REG[7:5] XWDLEN1 field and the McBSPi.MCBSPLP\_XCR2\_REG[7:5] XWDLEN2 field.

The difference of use is explained to [Section 23.5.4.8.4.1, Number of Phases, Words, and Bits per Frame](#).

The various possibilities of word length are 8, 12, 16, 20, 24, and 32 bits (for field values, see [Section 23.5.6, McBSP Register Manual](#))

Bits coming from the mcbspi\_dr pin are held in the RSR until it holds a full serial word, then the word is passed to the RB and to the McBSPi.MCBSPLP\_DRR\_REG register.

During transmission, XSR accepts new data from XB after a full serial word has been passed from XSR to the mcbspi\_dx pin.

In the example in [Figure 23-134](#), an 8-bit word size was defined (see the transfer of the 8-bit word B).

### 23.5.4.8.3.3 Frames and Frame Synchronization

One or more words (up to 128) are transferred in a group called a frame. The software defines how many words are in a frame by programming:

- For the receiver: The McBSPi.MCBSPLP\_RCR1\_REG[14:8] RFRLLEN1 field and the McBSPi.MCBSPLP\_RCR2\_REG[14:8] RFRLLEN2 field.

- For the transmitter: The McBSPi.MCBSPLP\_XCR1\_REG[14:8] XFRLEN1 field and the McBSPi.MCBSPLP\_XCR2\_REG[14:8] XFRLEN2 field.

The difference between these registers is explained to [Section 23.5.4.8.4.1, Number of Phases, Words, and Bits per Frame](#). For the corresponding between field value and words number, see [Section 23.5.6, McBSP Register Manual](#).

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-synchronization signals (FSG) to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP module begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP module receives/transmits the next frame, and so on.

Pulses on the receive frame-synchronization (FSR\_int) signal initiate frame transfers on mcbspi\_dr. Pulses on the transmit frame-sync (FSX\_int) signal initiate frame transfers on mcbspi\_dx. FSR\_int or FSX\_int signals can be derived from a pin at the boundary of the McBSP module (mcbbsp4\_fsr and mcbspi\_fsx respectively) or derived from inside the McBSP module (see [Figure 23-129](#)). The frame-sync source is selected by programming the McBSPi.MCBSPLP\_PCR\_REG[11] FSXM bit and the McBSPi.MCBSPLP\_PCR\_REG[10] FSRM bit respectively.

When the McBSPi.MCBSPLP\_PCR\_REG[11] FSXM bit (transmitter frame-sync mode) is set to:

- '0', FSX\_int is derived from an external source and mcbspi\_fsx is an input pin.
- '1', FSX\_int is determined by the McBSPi.MCBSPLP\_SRGR2\_REG[12] FSGM bit and mcbspi\_fsx is an output pin.

For the McBSPi.MCBSPLP\_PCR\_REG[10] FSRM bit (receiver frame-sync mode), is set to:

- '0', FSR\_int is generated by an external source and mcbbsp4\_fsr is an input pin
- '1', FSR\_int is generated internally by sample rate generator. The mcbbsp4\_fsx is an output pin except when McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit = 0x1

In the example in [Figure 23-130](#), a one-word frame is transferred when a frame-synchronization pulse occurs. The polarities of FSR and FSX signals are programmable by bits on McBSPi.MCBSPLP\_PCR\_REG register.

The McBSPi.MCBSPLP\_PCR\_REG[3] FSXP defines the transmit frame-sync polarity:

- When set to '0', frame-sync pulse FSX is active high
- When set to '1', frame-sync pulse FSX is active low

The McBSPi.MCBSPLP\_PCR\_REG[2] FSRP defines the receive frame-sync polarity:

- When set to '0', frame-sync pulse FSR is active high
- When set to '1', frame-sync pulse FSR is active low

In McBSP operation, the inactive-to-active transition of the frame-synchronization signal indicates the start of the next frame. For this reason, the frame-synchronization signal may be high for an arbitrary number of clock cycles. Only after the signal is recognized to have gone inactive, and then active again, does the next frame synchronization occur.

#### **23.5.4.8.3.4 Detecting Frame-Synchronization Pulses, Even in Reset State**

The McBSP module can generate receive and transmit interrupts to the Cortex-A9 MPU/DSP subsystems to indicate specific events in the McBSP module. To facilitate detection of frame synchronization, these interrupts can be sent in response to frame-synchronization pulses (see [Section 23.5.5, McBSP Basic Programming Model](#) for further details).

Unlike other serial port interrupt modes, this mode can operate while the associated portion of the serial port is in reset (such as activating receive interrupt when the receiver is in reset). In this case, McBSPi.MCBSPLP\_PCR\_REG[0] FSRM bit/McBSPi.MCBSPLP\_PCR\_REG[1] FSXM bit and McBSPi.MCBSPLP\_PCR\_REG[2] FSRP bit/McBSPi.MCBSPLP\_PCR\_REG[3] FSXP bit still select the appropriate source and polarity of frame synchronization. Thus, even when the serial port is in the reset state, these signals are synchronized to the interface clock (MCBSPi\_ICLK) and then sent to the Cortex-A9 MPU/DSP subsystem in the form of receive interrupt and transmit interrupt at the point where they feed the receiver and transmitter of the serial port. Consequently, a new frame-synchronization pulse can be detected, and then, the Cortex-A9 MPU/DSP subsystem can take the serial port out of reset safely.

### 23.5.4.8.3.5 Ignoring Frame-Synchronization Pulses

The McBSP module ignores transmit and/or receive frame-synchronization pulses if the frame transfer was started by a previous frame-synchronization pulse (unexpected frame-synchronization pulses). The McBSP module does not support features like retransmit or re-receive of an erroneous frame or word. The receiver or transmitter ignores frame-synchronization pulses until the desired frame length or number of words is reached. For more details on unexpected frame-synchronization pulses, see [Section 23.5.4.10.3, Unexpected Receive Frame-sync Pulse](#) or [Section 23.5.4.10.6, Unexpected Transmit Frame-sync Pulse](#)

### 23.5.4.8.3.6 Frame Frequency

The frame frequency is determined by the period between frame-synchronization pulses and is defined as shown in the following equation:

$$\text{Frame frequency} = \text{Clock frequency} / (\text{Number of clock cycles between two rising edges [or falling edges] of two consecutive frame synchronization pulses})$$

The frame frequency can be increased by decreasing the time between frame-synchronization pulses (limited only by the number of bits per frame). As the frame transmit frequency increases, the inactivity period between the data packets for adjacent transfers decreases to zero.

### 23.5.4.8.3.7 Maximum Frame Frequency

The minimum number of clock cycles between frame synchronization pulses is equal to the number of bits transferred per frame. The maximum frame frequency is defined as shown in the following equation:

$$\text{Maximum frame frequency} = \text{clock frequency} / \text{Number of bits per frame}$$

[Figure 23-132](#) below shows the McBSP operating at maximum packet frequency. At maximum packet frequency, the data bits in consecutive packets are transmitted contiguously with no inactivity between bits.

**Figure 23-132. McBSP Operating at Maximum Packet Frequency**

If there is a 1-bit data delay as shown in [Figure 23-132](#), the frame-synchronization pulse overlaps the last bit transmitted in the previous frame. Effectively, this permits a continuous stream of data, back-to-back transfers.

---

**NOTE:** For McBSPi.MCBSPLP\_XCR2\_REG[1:0] XDATDLY = 0x0 (0-bit data delay), the first bit of data is transmitted asynchronously to the internal transmit clock signal (CLKX\_int). For more details, see [Table 23-384](#).

---

### 23.5.4.8.4 Frame Phases (Dual-Phase Frame I2S Support)

The McBSP module allows you to configure each frame to contain one or two phases. The support for dual-phase frames is required to provide I2S fully compliant capabilities (audio left and right channels—stereo audio stream).

**CAUTION**

The limitation on dual-phase frame support is that the number of words per phase must be set to 1 for both first and second phase. It is the only possible value for word per frame when using the dual phase frame.

The number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers. For example, a user might define a frame as consisting of one phase containing one word of 16 bits, followed by a second phase consisting of one word of 32 bits. This configuration allows the user to compose frames for custom applications such as I2S protocol.

**23.5.4.8.4.1 Number of Phases, Words, and Bits per Frame**

Table 23-335 below shows which bit fields in the receive control registers (McBSPi.MCBSPLP\_RCR1\_REG and McBSPi.MCBSPLP\_RCR2\_REG) and in the transmit control registers (McBSPi.MCBSPLP\_XCR1\_REG and McBSPi.MCBSPLP\_XCR2\_REG) determine the number of phases per frame, the number of words per frame, and the number of bits per word for each phase, for both receiver and transmitter. The maximum number of words per frame is limited to 2 when using dual-phase frames (one word for each phase), and to 128 for a single-phase frame. The number of bits per word can be 8, 12, 16, 20, 24, or 32 bits.

The following legend applies to the table:

- RPHASE => McBSPi.MCBSPLP\_RCR2\_REG[15] RPHASE bit
- XPHASE => McBSPi.MCBSPLP\_XCR2\_REG[15] XPHASE bit
- RFLEN1 => McBSPi.MCBSPLP\_RCR1\_REG[14:8] RFLEN1 field
- RFLEN2 => McBSPi.MCBSPLP\_RCR2\_REG[14:8] RFLEN2 field
- XFLEN1 => McBSPi.MCBSPLP\_XCR1\_REG[14:8] XFLEN1 field
- XFLEN2 => McBSPi.MCBSPLP\_XCR2\_REG[14:8] XFLEN2 field
- RWDLEN1 => McBSPi.MCBSPLP\_RCR1\_REG[7:5] RWDLEN1 field
- RWDLEN2 => McBSPi.MCBSPLP\_RCR2\_REG[7:5] RWDLEN2 field
- XWDLEN1 => McBSPi.MCBSPLP\_XCR1\_REG[7:5] XWDLEN1 field
- XWDLEN2 => McBSPi.MCBSPLP\_XCR2\_REG[7:5] XWDLEN2 field

**Table 23-335. Phases, Words and Bits per Frame Control Bit**

Operation	Number of phases	Words per frame set with	Bits per word set with
Reception	1 (RPHASE=0)	RFLEN1	RWDLEN1
Reception	2 (RPHASE=1)	RFLEN1=0x0 and RFLEN2=0x0	RWDLEN1 for phase 1 RWDLEN2 for phase 2
Transmission	1 (XPHASE=0)	XFLEN1	XWDLEN1
Transmission	2 (XPHASE=1)	XFLEN1=0x0 and XFLEN2=0x0	XWDLEN1 for phase 1 XWDLEN2 for phase 2

**23.5.4.8.4.2 Single-Phase Frame Example**

Figure 23-133 below shows an example of a single-phase data frame containing one 8-bit word. Because the transfer is configured for one data bit delay, the data on the mcbspi\_dx and mcbspi\_dr pins are available one clock cycle after FS(R/X) goes active. The following table shows the assumptions used in the example of this figure.

**Table 23-336. Assumptions for the Single-Phase Frame Example**

Assumption	Value	Bit or Field Name
Single-phase frame	'0'	McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit
		McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit
One word per frame	0x0	McBSPi.MCBSPLP_RCR1_REG[14:8] RFLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[14:8] XFLEN1 field

**Table 23-336. Assumptions for the Single-Phase Frame Example (continued)**

Assumption	Value	Bit or Field Name
8-bit word length	0x0	McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field
word length in register2	ignored	McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLLEN2 field
		McBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2 field
Receive data clocked on falling edge	'0'	McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit
Transmit data clocked on rising edge		McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit
Active-high frame-sync signals	'0'	McBSPi.MCBSPLP_PCR_REG[2] FSRP bit
		McBSPi.MCBSPLP_PCR_REG[3] FSXP bit
1-bit data delay	01b	McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field
		McBSPi.MCBSPLP_XCR2_REG[1:0] XDARDLY field

**Figure 23-133. Single-Phase Frame for a McBSP Data Transfer**

mcbasp-028

**23.5.4.8.4.3 Dual-Phase Frame Example**

Figure 23-134 below shows an example of a frame. The first phase consists of one word of 16 bits, followed by a second phase of one word of 8 bits. The entire bit stream in the frame is contiguous. There are no gaps between words/phases. Table 23-337 shows the assumptions used to the example in Figure 23-134.

**Table 23-337. Assumptions for the Dual-Phase Frame Example**

Assumption	Value	Bit or Field name
Single-phase frame	'1'	McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit
		McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit
One word per frame	0x0	McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 field
16-bit word length	0x0	McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field
8-bit word length	0x2	McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLLEN2 field
		McBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2 field
Receive data clocked on falling edge	'0'	McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit
Transmit data clocked on rising edge		McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit
Active-high frame-sync signals	'0'	McBSPi.MCBSPLP_PCR_REG[2] FSRP bit
		McBSPi.MCBSPLP_PCR_REG[3] FSXP bit
0-bit data delay	00b	McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field
		McBSPi.MCBSPLP_XCR2_REG[1:0] XDARDLY field

**Figure 23-134. Dual-Phase Frame for a McBSP Data Transfer**

**23.5.4.8.5 McBSP Reception**

This section explains the fundamental process of reception in the McBSP module. For details about how to program the McBSP receiver, see [Section 23.5.5, McBSP Basic Programming Model](#), [Section 23.5.5.4, Interrupt Configuration](#), and [Section 23.5.5.5, Receiver Configuration](#).

[Figure 23-135](#) and [Figure 23-136](#) below show how reception occurs in the McBSP module. A description of the process follows the figures. [Figure 23-135](#) shows the physical path for the data.

**Figure 23-135. McBSP Reception Physical Data Path**

[Figure 23-136](#) is a timing diagram showing signal activity for one possible reception scenario.

**Figure 23-136. McBSP Reception Signal Activity**

RRDY: Status of receiver ready bit (high is 1)

The following process describes how data travels from the mcbspi\_dr pin to the MPU/DSP subsystem or to the sDMA controller:

1. The McBSP module waits for a receive frame-synchronization pulse on FSR\_int.
2. When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.MCBSPLP\_RCR2\_REG[1:0] RDATDLY bits. In the preceding timing diagram a 1-bit data delay is selected.
3. The McBSP module accepts data bits on the mcbspi\_dr pin and shifts them into the RSR. For details on choosing a word length, see [Section 23.5.5.6, Transmitter Configuration](#).
4. When a full word is received, the McBSP module copies the contents of the RSR to the RB, provided that RB is not full.
5. When the programmed receive threshold is reached (McBSPi.MCBSPLP\_THRSH1\_REG[6:0] RTHRESHOLD field), the McBSP module asserts the receiver ready bit

(McBSPi.MCBSPLP\_SPCR1\_REG[1] RRDY bit). This indicates that receive data is ready to be read by the Cortex-A9 MPU/DSP subsystem or the sDMA controller by accessing McBSPi.MCBSPLP\_DRR\_REG register.

The data copied from RB to McBSPi.MCBSPLP\_DRR\_REG is justified and bit filled according to the McBSPi.MCBSPLP\_SPCR1\_REG[14:13] RJUST field.

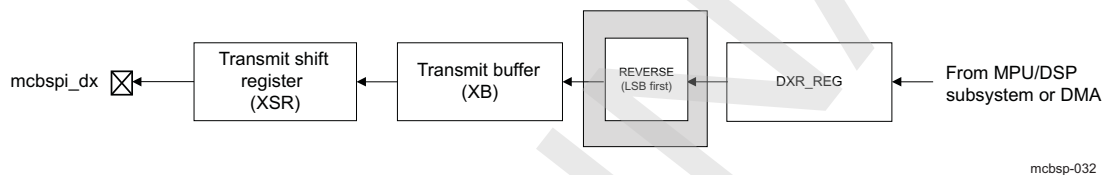

- The Cortex-A9 MPU/DSP subsystem or the sDMA controller reads the data from the data receive register. When the RB is empty, McBSPi.MCBSPLP\_SPCR1\_REG[1] RRDY bit is cleared.

#### 23.5.4.8.6 McBSP Transmission

This section explains the fundamental process of transmission in the McBSP module. For details about how to program the McBSP transmitter, see [Section 23.5.5, McBSP Basic Programming Model](#) and [Section 23.5.5.6, Transmitter Configuration](#).

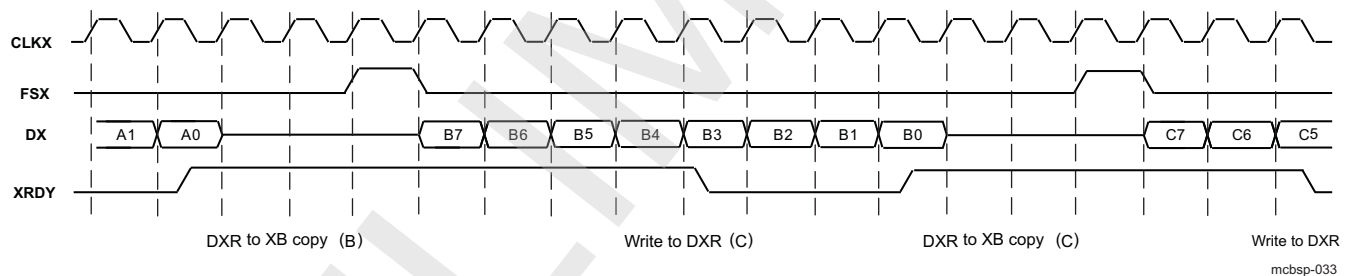

Figures below show how transmission occurs in the McBSP module. A description of the process follows the figures. [Figure 23-137](#) shows the physical path for the data.

**Figure 23-137. McBSP Transmission Physical Data Path**

[Figure 23-138](#) is a timing diagram showing signal activity for one possible transmission scenario.

**Figure 23-138. McBSP Transmission Signal Activity**

**XRDY: Status of transmitter ready bit (high is 1)**

- The Cortex-A9 MPU/DSP subsystem or the sDMA controller writes data to the data transmit register (McBSPi.MCBSPLP\_DXR\_REG). When the XB is reached the transmitter ready bit (McBSPi.MCBSPLP\_SPCR2\_REG[1] XRDY bit) is cleared to indicate that the transmitter is not ready for new data. For details on choosing a word length, see [Table 23-380](#).
- When new data arrives in McBSPi.MCBSPLP\_DXR\_REG register, the McBSP module copies the content of the data transmit register to the XB. In addition, the transmit ready bit (McBSPi.MCBSPLP\_SPCR2\_REG[1] XRDY bit) is set as long as the buffer contains at least the transmit threshold number of free locations (McBSPi.MCBSPLP\_THRSH2\_REG[6:0] XTHRESHOLD field). This indicates that the transmitter is ready to accept new data from the MPU/DSP subsystem or the sDMA controller.
- The McBSP module waits for a transmit frame-synchronization pulse on FSX\_int.
- When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.MCBSPLP\_XCR2\_REG[1:0] XDADLY field.  
In the preceding timing diagram, a 1-bit data delay is selected.
- The McBSP module shifts data bits from the XSR to the mcbspi\_dx pin.

#### 23.5.4.8.7 Enable/Disable the Transmit and Receive Processes

The McBSP module has the option to stop-resume the transmit/receive process while the module is in functional mode (out of transmit/receive reset).

When the transmit/receive disable bit (McBSPi.MCBSPLP\_XCCR\_REG[0] XDISABLE/McBSPi.MCBSPLP\_RCCR\_REG[0] RDISABLE) is set, the McBSP module stops the transmit/receive operation at the next frame boundary (frame corruption avoided).

During the receive disable state, the frames that are sent (when FSR signal is asserted while receive disable) by the remote device are lost, and receive buffer overflow status bit (McBSPi.MCBSPLP\_IRQSTATUS\_REG[5] ROVFLSTAT) is not set. Also, the frames received by the remote device while McBSPi.MCBSPLP\_XCCR\_REG[0] XDISABLE bit is set (when FSX signal is asserted while transmit disable) are meaningless undefined data frames, and transmit buffer underflow status bit (McBSPi.MCBSPLP\_IRQSTATUS\_REG[11] XUNDFLSTAT) is not set. The presence of the frame synchronization, while transmit/receive process is disabled, can be checked by reading the transmit/receive Frame-sync interrupt status: McBSPi.MCBSPLP\_IRQSTATUS\_REG[8] XFSX / McBSPi.MCBSPLP\_IRQSTATUS\_REG[1] RFSR bits.

As soon as the McBSPi.MCBSPLP\_XCCR\_REG[0] XDISABLE/McBSPi.MCBSPLP\_RCCR\_REG[0] RDISABLE bit is cleared, the transmit/receive process resumes at the next frame boundary.

---

**NOTE:** It is not recommended to use this mechanism together with the possibility to interrogate the transmit/receive buffer status register (McBSPi.MCBSPLP\_XBUFFSTAT\_REG[7:0] XBUFFSTAT/McBSPi.MCBSPLP\_RBUFFSTAT\_REG[7:0] RBUFFSTAT field indicating the occupied/available buffer locations), since this register is an interface clock (MCBSPi\_ICLK) synchronous register and does not reflect the exact number of occupied/free locations available on the functional clock domain.

---

#### **23.5.4.8.8** *MCBSP Data Transfer Mode*

---

**NOTE:** For all examples in this section, the configured CLKX edge is the rising edge (McBSPi.MCBSPLP\_PCR\_REG[1] CLKXP bit = 0x0) and the configured CLKR edge is the falling edge (McBSPi.MCBSPLP\_PCR\_REG[0] CLKRP bit = 0x0). These are the reset values.

In timing diagrams below, a 1-bit data delay is selected (McBSPi.MCBSPLP\_RCR2\_REG[1:0] RDATDLY bit field = 0x01 and McBSPi.MCBSPLP\_XCR2\_REG[1:0] XDATDLY bit field = 0x01), because data often follows a 1-cycle active frame-synchronisation.

---

McBSP modules can support 2 edge selection modes for transmit and receive data transfer at the system level:

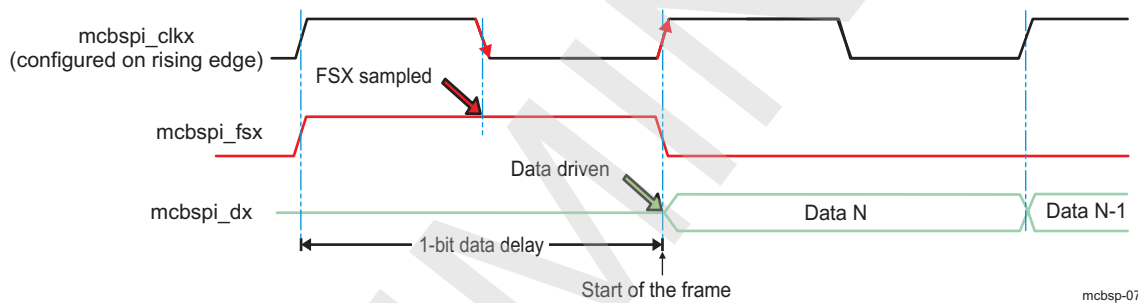

- The full cycle mode, for which one clock period is used to transfer the data, generated on one edge and captured on the same edge (one clock period later).
- The half cycle mode, for which one half clock period is used to transfer the data, generated on one edge and captured on the opposite edge (one half clock period later). Note that a new data is generated only every clock period, which permits to guarantee the required hold time.

#### **23.5.4.8.8.1** *Transmit Full Cycle Mode*

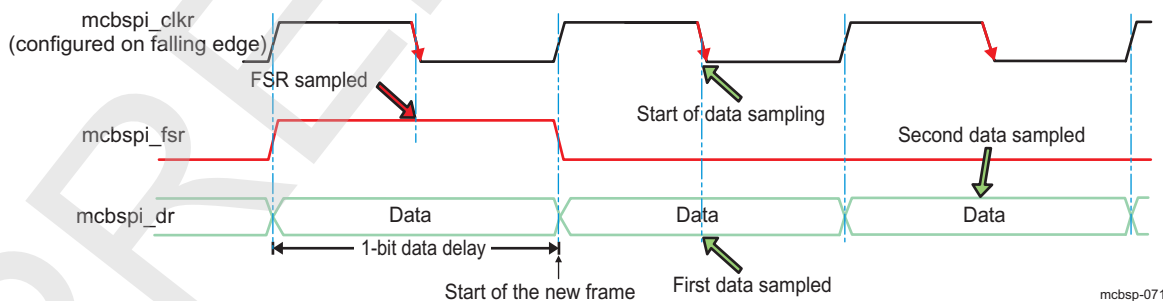

When configured in full cycle mode (McBSPi.MCBSPLP\_XCCR\_REG[11] XFULL\_CYCLE bit = 0x1), the FSX signal is sampled on the configured CLKX edge and the data is driven on the same configured edge. See [Figure 23-139](#).

**Figure 23-139. Transmit Full Cycle Timing Diagram****23.5.4.8.8.2 Transmit Half Cycle Mode**

When configured in half cycle mode (McBSPi.MCBSPLP\_XCCR\_REG[11] XFULL\_CYCLE bit = 0x0, reset value), the FSX signal is sampled on the opposite configured CLKX edge and the data is driven on the next configured edge. See [Figure 23-140](#).

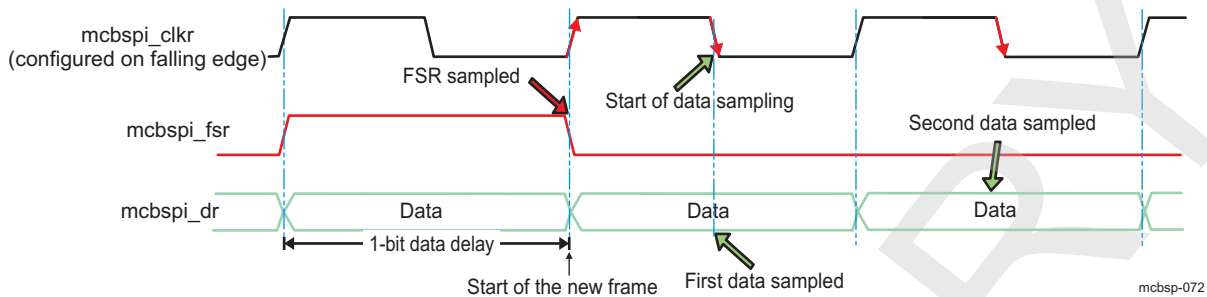

**Figure 23-140. Transmit Half Cycle Timing Diagram****23.5.4.8.8.3 Receive Full Cycle Mode**

When configured in full cycle mode (McBSPi.MCBSPLP\_RCCR\_REG[11] RFULL\_CYCLE bit = 0x1, reset value), the FSR signal is sampled on the configured CLKR edge and the data is driven on the same configured edge. See [Figure 23-141](#).

**Figure 23-141. Receive Full Cycle Timing Diagram****23.5.4.8.8.4 Receive Half Cycle Mode**

When configured in half cycle mode (McBSPi.MCBSPLP\_RCCR\_REG[11] RFULL\_CYCLE bit = 0x0), the FSR signal is sampled on the opposite configured CLKR edge and the data is driven on the next configured edge. See [Figure 23-142](#).

Figure 23-142. Receive Half Cycle Timing Diagram

23.5.4.9 McBSP SRG

The McBSP module contains an internal SRG that can be used to generate an internal data clock (CLKG) and an internal frame-synchronization signal (FSG). CLKG can be used for bit shifting on the data receive pin (mcbspi\_dr) and/or the data transmit pin (mcbspi\_dx). FSG can be used to initiate frame transfers on mcbspi\_dr pin and/or mcbspi\_dx pin. Figure 23-143 is a conceptual block diagram of the SRG.

Figure 23-143. Conceptual Block Diagram of the Sample Rate Generator

The source clock for the SRG (labeled **CLKSRG** in the diagram) can be supplied by either the interface clock (**McBSPi\_ICLK**), or the functional clock (**CLKS** input), or by an external pin (**mcbspi\_clkx**, or **mcbbsp4\_clkr**). The source is selected with the **McBSPi.MCBSPLP\_PCR\_REG[7]** **SCLKME bit** and the **McBSPi.MCBSPLP\_SRGR2\_REG[13]** **CLKSM bit**.

If a pin or **CLKS** signal is used, the polarity of the incoming signal can be inverted with the appropriate polarity bit (**McBSPi.MCBSPLP\_SRGR2\_REG[14]** **CLKSP bit**, **McBSPi.MCBSPLP\_PCR\_REG[1]** **CLKXP bit**, or **McBSPi.MCBSPLP\_PCR\_REG[0]** **CLKRP bit**).

The SRG has a three-stage clock divider that gives **CLKG** and **FSG** programmability.

The three stages provide:

- Clock divide-down: The source clock (CLKSRG) is divided according to the McBSPi.MCBSPLP\_SRGR1\_REG[7:0] CLKGDV field to produce CLKG signal
- Frame period divide-down: CLKG is divided according to the McBSPi.MCBSPLP\_SRGR2\_REG[11:0] FPER field to control the period from the start of a frame-pulse to the start of the next pulse
- Frame-synchronization pulse-width countdown: CLKG cycles are counted according to the McBSPi.MCBSPLP\_SRGR1\_REG[15:8] FWID field to control the width of each frame-synchronization pulse

---

**NOTE:** The McBSP module cannot operate at an internal functional frequency faster than L4 interface frequency divided by 2. Choose an input clock frequency and a McBSPi.MCBSPLP\_SRGR1\_REG[7:0] CLKGDV value such that CLKG is less than or equal to L4 interface frequency divided by 2.

---

In addition to the three-stage clock divider, the sample rate generator has a frame-synchronization pulse detection and clock synchronization module that allows synchronization of the clock divide down with an incoming frame-synchronization pulse on the mcbbsp4\_fsr pin. This feature is enabled or disabled with the McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit.

CLKG is used as source to generate the output clocks CLKX/CLKR when the McBSPi.MCBSPLP\_PCR\_REG[9] CLKXM / McBSPi.MCBSPLP\_PCR\_REG[8] CLKRM bit indicates that the clock is an output. The output CLKX/CLKR is generated according to the clock polarity setting (see [Figure 23-130](#)).

For details on getting the sample rate generator ready for operation, see [Section 23.5.5, McBSP Basic Programming Model](#).

#### 23.5.4.9.1 Clock Generation in the SRG

The SRG can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both. Use of the SRG to drive clocking is controlled by the clock mode bits (McBSPi.MCBSPLP\_PCR\_REG[9] CLKXM and McBSPi.MCBSPLP\_PCR\_REG[8] CLKRM) and polarity mode bits (McBSPi.MCBSPLP\_PCR\_REG[1] CLKXP and McBSPi.MCBSPLP\_PCR\_REG[0] CLKRP).

When a clock mode bit is set to 1 (CLKRM=1 for reception, CLKXM=1 for transmission), the corresponding data clock (CLKR for reception, CLKX for transmission) is driven by the internal SRG output clock (CLKG) according to the polarity setting.

The effects of this setting on the McBSP module are partially affected by the use of the digital loopback (DLB) mode, the analog loop back (ALB) mode and by the synchronous receive/transmit setting, respectively, as described in [Table 23-338](#). The ALB mode is selected with the McBSPi.MCBSPLP\_SPCR1\_REG[15] ALB bit. The DLB mode is selected with the McBSPi.MCBSPLP\_XCCR\_REG[5] DLB bit. The synchronous setting is controlled by input signals. These signals are defined by the control registers of the Control Module (more details, see [Chapter 18, Control Module](#)).

When using the SRG as a clock source, make sure the SRG is enabled (McBSPi.MCBSPLP\_SPCR2\_REG[6] GRST bit =1).

**Table 23-338. Effects of DLB and ALB Bits on Clock Modes**

Mode Bit Settings		Effect
CLKRM=1	DLB=0 and ALB = 0 (Digital and analog loop back mode disabled)	mcbbsp1_clkx is an output pin driven by the SRG output clock (CLKG).
	DLB=0 and ALB = 1 (Digital loop back mode disabled and Analog loop back mode enabled)	mcbbsp1_clkx is an output pin driven by the SRG output clock (CLKG). The receiver functional part internal clock is driven by CLKX input signal provided by mcbbsp1_clkx pin. The source of CLKX depends on the CLKXM bit. The receive frame synchronization is driven by FSX input signal provided by mcbbsp1_fsx pin. The receive data is driven by the DX input loop-back pin (mcbbsp1_dx).
	DLB=1 & ALB = 0 (Digital loop back mode enabled and Analog loop back mode disabled)	The SRG and the frame synchronization generator must be enabled. The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity). The transmit data is connected to the DR input data. Note that in digital loop back mode no serial link activity will be seen by the remote device.
	DLB=1 & ALB = 1 (reserved mode)	Undefined functionality.
CLKXM=1	DLB=0 & ALB = 0 (Digital & analog loop back mode disabled)	mcbbsp1_clkx is an output pin driven by the SRG output clock (CLKG).
	DLB=0 & ALB = 1 (Digital loop back mode disabled and Analog loop back mode enabled)	mcbbsp1_clkx is an output pin driven by the SRG output clock (CLKG).
	DLB=1 & ALB = 0 (Digital loop back mode enabled and Analog loop back mode disabled)	The SRG and the frame synchronization generator need to be enabled. The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity). The transmit data is connected to the DR input data. Note that in digital loop back mode no serial link activity will be seen by the remote device.
	DLB=1 & ALB = 1 (reserved mode)	Undefined functionality.
	CONTROL_MCBSPPLP[30] ALBCTRLRX_CLKX bit =1 (synchronous setting and DLB = 0 & ALB = 0)	CLKX is an output pin driven by the SRG output clock (CLKG). CLKR is connected to the CLKX.

#### 23.5.4.9.2 Frame Sync Generation in the SRG

The SRG can produce a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both.

If you want the receiver to use FSG for frame synchronization, make sure McBSPi.MCBSPPLP\_PCR\_REG[10] FSRMbit =1. (When FSRM=0, receive frame synchronization is supplied via the mcbbsp4\_fsr pin.)

If you want the transmitter to use FSG for frame synchronization, you must set:

- McBSPi.MCBSPPLP\_PCR\_REG[11] FSXM = 1: This indicates that transmit frame synchronization is supplied by the McBSP module itself rather than from the mcbbsp1\_fsx pin.
- MCBSPPLP\_SRGR2\_REG[12] FSGM=1: This indicates that when FSXM=1, transmit frame synchronization is supplied by the SRG.

**NOTE:** When FSGM=0 and FSXM=1, the transmit frame-sync signal (FSX) is generated when XB is not empty. When FSGM = 0, McBSPi.MCBSPLP\_SRGR2\_REG[11:0] FPER and McBSPi.MCBSPLP\_SRGR1\_REG[15:8] FWID field are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition).

In either case, the SRG must be enabled (McBSPi.MCBSPLP\_SPCR2\_REG[6] GRST bit=1) and the frame-synchronization logic in the SRG must be enabled (McBSPi.MCBSPLP\_SPCR2\_REG[7] FRST bit=0).

#### 23.5.4.9.2.1 Choosing the Width of the Frame-sync Pulse

Each pulse on FSG has a programmable width. You program the McBSPi.MCBSPLP\_SRGR1\_REG[15:8] FWID field, and the resulting pulse width is (FWID+1)CLKGcycles, where CLKG is the output clock of the SRG. The range is from 1 to 256 clock periods.

#### 23.5.4.9.2.2 Controlling the Period Between the Starting Edges of Frame Sync Pulses

You can control the amount of time from the starting edge of one FSG pulse to the starting edge of the next FSG pulse. This period is controlled in one of two ways, depending on the configuration of the SRG:

- If the SRG is using an external input clock and McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNCbit =1, FSG pulses in response to an inactive-to-active transition on the mcbasp4\_fsr pin. Thus, an external device controls the frame-synchronization period.
- Otherwise, the software program the McBSPi.MCBSPLP\_SRGR2\_REG[11:0] FPER field, and the resulting frame-synchronization period is (FPER+1)CLKGcycles, where CLKG is the output clock of the SRG. The range is from 1 to 4096 clock periods.

#### 23.5.4.9.2.3 Keeping FSG Synchronized to an External Clock

When an external signal is selected to drive the SRG, the McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit and the mcbasp4\_fsr pin can be used to configure the timing of FSG pulses.

McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC=1 ensures that the McBSP module and an external device are dividing down the input clock with the same phase relationship.

If McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC=1, an inactive-to-active transition on the mcbasp4\_fsr pin triggers a resynchronization of CLKG and generation of FSG.

#### 23.5.4.9.3 Synchronizing SRG Outputs to an External Clock

The SRG can produce a clock signal (CLKG) and a FSG based on an input clock signal that is either the interface clock signal (MCBSPi\_ICLK), or the CLKS signal (PRCM functional clock or mcbasp\_clks), or a signal at the mcbasp4\_clkr, or mcbspi\_clkx pin. When an external clock (mcbasp\_clks, or mcbasp4\_clkr, or mcbspi\_clkx) is selected to drive the SRG, the McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit and the mcbasp4\_fsr pin can be used to control the timing of CLKG and the pulsing of FSG relative to the chosen input clock. Make GSYNC=1 so that the McBSP module and an external device divide down the input clock with the same phase relationship.

If the McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit=1:

- An inactive-to-active transition on the mcbasp4\_fsr pin triggers a resynchronization of CLKG signal and a pulsing of FSG signal.
- CLKG signal always begins with a high state after synchronization.
- FSR signal is always detected at the same edge of the input clock signal that generates CLKG signal, no matter how long the FSR pulse is.
- The McBSPi.MCBSPLP\_SRGR2\_REG[11:0] FPER field are ignored because the frame-synchronization period on FSG is determined by the arrival of the next frame-synchronization pulse on the mcbasp4\_fsr pin.

If the McBSPi.MCBSPLP\_SRGR2\_REG[15] GSYNC bit=0, CLKG signal runs freely and is not resynchronized, and the frame-synchronization period on FSG signal is determined by McBSPi.MCBSPLP\_SRGR2\_REG[11:0] FPER field.

**23.5.4.9.3.1 Operating the Transmitter Synchronously with the Receiver**

When the `McBSPi.MCBSPLP_SRGR2_REG[15]` GSYNC bit=1, the transmitter can operate synchronously with the receiver, provided that the FSX signal is programmed to be driven by FSG signal (`McBSPi.MCBSPLP_SRGR2_REG[12]` FSGM=1 and `McBSPi.MCBSPLP_PCR_REG[11]` FSXM='1'). If the FSR input signal has appropriate timing so that it can be sampled by the falling edge of CLKG signal, it can be used, instead, by setting `McBSPi.MCBSPLP_PCR_REG[11]` FSXM=0 and connecting FSR signal to FSX externally.

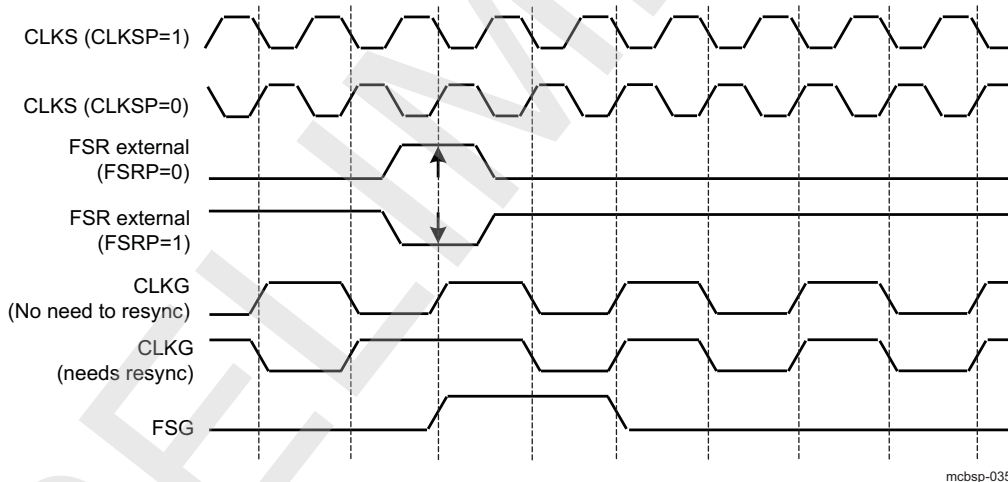

The SRG clock drives the transmit and receive clocking (`McBSPi.MCBSPLP_PCR_REG[8]` CLKRMbit and `McBSPi.MCBSPLP_PCR_REG[9]` CLKXM bit are set to '1'). Therefore, the CLK(R/X) pin must not be driven by any other driving source.

**23.5.4.9.3.2 Synchronization Examples**

Figure 23-144 and Figure 23-145 show the clock and frame-synchronization operation with various polarities of CLKS (the chosen input clock) and FSR signals. These figures assume `McBSPi.MCBSPLP_SRGR1_REG[15:8]` FWID = 0x0, for an FSG pulse that is oneCLKGcycle wide. The `McBSPi.MCBSPLP_SRGR2_REG[11:0]` FPER field are not programmed; the period from the start of a frame-synchronization pulse to the start of the next pulse is determined by the arrival of the next inactive-to-active transition on the `mcbasp4_fsr` pin.

Each figure shows what happens to CLKG signal when the `McBSPi.MCBSPLP_SRGR2_REG[15]` GSYNC bit = 1 and if it is initially synchronized or if it is not initially synchronized. Figure 23-145 has a slower CLKG frequency (it has a larger divide-down value in the `McBSPi.MCBSPLP_SRGR1_REG[7:0]` CLKGDV field).

**Figure 23-144. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 0x1)**

**Figure 23-145. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 0x3)**

### 23.5.4.10 McBSP Exception/Error Conditions

#### 23.5.4.10.1 Introduction

There are several serial port events that can constitute a system error. Any error conditions can be a source of an interrupt:

- Receiver overrun (McBSPi.MCBSPLP\_IRQSTATUS\_REG[5] ROVFLSTAT bit is set to '1', and legacy mode McBSPi.MCBSPLP\_SPCR1\_REG[2] RFULLbit is set to '1')

This occurs when RB is full and RSR are full with another new word shifted in from mcbspi\_dr. Therefore, McBSPi.MCBSPLP\_IRQSTATUS\_REG[5] ROVFLSTAT (McBSPi.MCBSPLP\_SPCR1\_REG[2] RFULL) indicates an error condition wherein any new data that can arrive at this time on mcbspi\_dr replaces the contents of the RSR, and the previous word is lost. The RSR continues to be overwritten as long as new data arrives on mcbspi\_dr and McBSPi.MCBSPLP\_DRR\_REG register is not read. For more details about overrun in the receiver, see [Section 23.5.4.10.2, Overrun in the Receiver](#).
- Unexpected receive frame-synchronization pulse (McBSPi.MCBSPLP\_IRQSTATUS\_REG[0] RSYNCERRbit is set to '1', and legacy mode McBSPi.MCBSPLP\_SPCR1\_REG[3] RSYNCERR bit is set to '1')

This occurs during reception when an unexpected frame-synchronization pulse arrives. An unexpected frame-synchronization pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been received. Such a pulse is ignored by the receiver, but sets the McBSPi.MCBSPLP\_SPCR1\_REG[3] RSYNCERR bit. For more details about receive frame-synchronization errors, see [Section 23.5.4.10.3, Unexpected Receive Frame-Sync Pulse](#).
- Receiver underflow (McBSPi.MCBSPLP\_IRQSTATUS\_REG[4] RUNDLSTAT bit is set to '1')

This occurs when sDMA controller or MPU/DSP subsystem reads data from an empty receive buffer. For more details about underflow in the receiver, see [Section 23.5.4.10.4, Underflow in the Receiver](#).
- Transmitter underflow (McBSPi.MCBSPLP\_IRQSTATUS\_REG[11] XUNDLSTAT bit is set to '1', and legacy mode McBSPi.MCBSPLP\_SPCR2\_REG[2] XEMPTY bit is set to '0')

If a new frame-synchronization signal arrives when XB is empty, the previous data in the XSR is sent again. This procedure continues for every new frame-synchronization pulse that arrives until McBSPi.MCBSPLP\_DXR\_REG register is loaded with new data (and the XB is no longer empty). For more details about underflow in the transmitter, see [Section 23.5.4.10.5, Underflow in the Transmitter](#).
- Unexpected transmit frame-synchronization pulse (McBSPi.MCBSPLP\_IRQSTATUS\_REG[7] XSYNCERRbit is set to '1', and legacy mode McBSPi.MCBSPLP\_SPCR2\_REG[3] XSYNCERRbit is set to '1')

This occurs during transmission when an unexpected frame-synchronization pulse arrives. An unexpected frame-synchronization pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been transferred. Such a pulse is ignored by the

transmitter, but sets the McBSPi.MCBSPLP\_SPCR2\_REG[3] XSYNCERR bit. For more details see [Section 23.5.4.10.6, Unexpected Transmit Frame-sync Pulse](#).

- Transmitter overflow (McBSPi.MCBSPLP\_IRQSTATUS\_REG[12] XOVLSTAT bit is set to '1') This occurs when sDMA controller or MPU/DSP subsystem writes data to a full XB. For more details about underflow in the receiver, see [Section 23.5.4.10.7, Overflow in the Transmitter](#).

### 23.5.4.10.2 Overrun in the Receiver

When McBSPi.MCBSPLP\_IRQSTATUS\_REG[5] ROVFLSTAT bit set to '1', and McBSPi.MCBSPLP\_SPCR1\_REG[2] RFULL bit set to '1' (legacy mode) indicates that the receiver has experienced overrun and is in an error condition. Receive overrun is set when all of the following conditions are met:

1. McBSPi.MCBSPLP\_DRR\_REG is not read even if the McBSPi.MCBSPLP\_IRQSTATUS\_REG[3] RRDY bit is set (legacy mode) and DMA or interrupt request has been asserted.
2. RB is full
3. RSR is full

As previously described, data arriving on mcbspi\_dr is continuously shifted into the Receive Shift Register (RSR). Once a complete word is shifted into the RSR, an RSR-to-RB copy can occur only if the RB is not full.

Either of the following events clears the legacy mode McBSPi.MCBSPLP\_SPCR1\_REG[2] RFULL bit and allows subsequent transfers to be read properly:

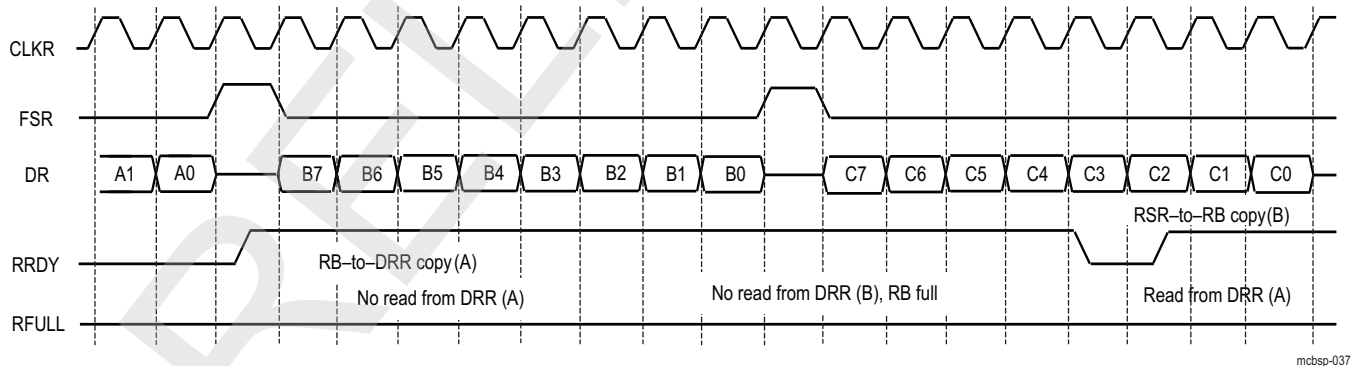

- The MPU/DSP subsystems or sDMA controller reads McBSPi.MCBSPLP\_DRR\_REG.
- The receiver is reset individually (McBSPi.MCBSPLP\_SPCR1\_REG[0] RRSTbit =0) or as part of a global reset.

Another frame-synchronization pulse is required to restart the receiver.

According to the McBSPi.MCBSPLP\_IRQENABLE\_REG register setting, this condition can generate the McBSPi\_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP\_IRQSTATUS\_REG register clears the interrupt.

Figure 23-146 shows the receive overrun condition.

Figure 23-146. Overrun in the McBSP Receiver

### 23.5.4.10.3 Unexpected Receive Frame-sync Pulse

#### 23.5.4.10.3.1 Possible Responses to Receive Frame-sync Pulses

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-synchronization pulse, and the receiver sets the receive frame-synchronization error bit McBSPi.MCBSPLP\_IRQSTATUS\_REG[0] RSYNCERR (and the legacy McBSPi.MCBSPLP\_SPCR1\_REG[3] RSYNCERR bit).

According to the `McBSPi.MCBSPLP_IRQENABLE_REG` register settings this condition can generate the `McBSPi_IRQ` line to be asserted low. Writing 1 to the corresponding bit in `McBSPi.MCBSPLP_IRQSTATUS_REG` register clears the interrupt.

Using the legacy mode, `McBSPi.MCBSPLP_SPCR1_REG[3]` `RSYNCERR` bit can be cleared only by a receiver reset or by writing 0 to this bit. If you want the McBSP module to notify the MPU/DSP subsystem of receive frame-synchronization errors, set the legacy mode receive interrupt with the `McBSPi.MCBSPLP_SPCR1_REG[5:4]` `RINTM` field. When `RINTM=0b11`, the McBSP module sends a receive interrupt (legacy mode) request to the MPU/DSP subsystems each time that `RSYNCERR` is set.

### 23.5.4.10.3.2 Example of an Unexpected Receive Frame-sync Pulse

Figure 23-147 shows an unexpected receive frame-synchronization pulse during normal operation of the serial port, with time intervals between data packets.

**NOTE:** The unexpected receive frame-synchronization pulse does not influence the data receive process, being ignored by the data receive state-machine.

**Figure 23-147. Unexpected Frame-sync Pulse During a McBSP Reception**

mcbasp-038

### 23.5.4.10.3.3 Preventing Unexpected Receive Frame-sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 `CLKR` cycles, depending on the value of the `McBSPi.MCBSPLP_RCR2_REG[1:0]` `RDATDLY` field. For each possible data delay, Figure 23-148 shows when a new frame-synchronization pulse on `FSR` can safely occur relative to the last bit of the current frame.

**Figure 23-148. Proper Positioning of Receive Frame-sync Pulses**

mcbasp-039

#### **23.5.4.10.4 Underflow in the Receiver**

The McBSP module indicates a receiver underflow condition by setting the McBSPi.MCBSPLP\_IRQSTATUS\_REG[4] RUNDLSTAT bit. This error occurs when sDMA controller or MPU/DSP subsystem reads data from an empty RB this happens only if the MPU/DSP subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request, or does not check the buffer status before reading data. According to the McBSPi.MCBSPLP\_IRQENABLE\_REG register settings this condition can generate the McBSPi\_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP\_IRQSTATUS\_REG register clears the interrupt.

#### **23.5.4.10.5 Underflow in the Transmitter**

The McBSP module indicates a transmitter empty (or underflow) condition by setting the McBSPi.MCBSPLP\_IRQSTATUS\_REG[11] XUNDLSTAT bit. Also the legacy mode McBSPi.MCBSPLP\_SPCR2\_REG[2] XEMPTY bit is cleared. Either of the following events activates XEMPTY bit (XEMPTY = 0):

- McBSPi.MCBSPLP\_DXR\_REG has not been loaded and XB is empty, and all bits of the data word in the XSR have been shifted out on the mcbspi\_dx pin.
- The transmitter is reset (by forcing McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST=0, or by an global reset) and is then restarted.

XEMPTY bit is deactivated (XEMPTY=1) when a new word in McBSPi.MCBSPLP\_DXR\_REG is transferred to Transmit Buffer (XB). If McBSPi.MCBSPLP\_PCR\_REG[11] FSXM=1 and McBSPi.MCBSPLP\_SRGR2\_REG[12] FSGM=0, the transmit frame-sync signal (FSX) is generated when Transmit Buffer (XB) is not empty. When McBSPi.MCBSPLP\_SRGR2\_REG[12] FSGM=0, McBSPi.MCBSPLP\_SRGR2\_REG[11:0] FPER and McBSPi.MCBSPLP\_SRGR1\_REG[15:8] FWID are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition). Otherwise, the transmitter waits for the next frame-synchronization pulse before sending out the next frame on mcbspi\_dx.

When the transmitter is taken out of reset (McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST=1), it is in a transmitter ready state (McBSPi.MCBSPLP\_SPCR2\_REG[1] XRDYbit =1) and transmitter empty (McBSPi.MCBSPLP\_SPCR2\_REG[2] XEMPTY=0) state. If McBSPi.MCBSPLP\_DXR\_REG is loaded by the MPU/DSP subsystem or the sDMA controller before internal FSX goes active high, a valid XB-to-XSR transfer occurs. This allows for the first word of the first frame to be valid even before the transmit frame-synchronization pulse is generated or detected. Alternatively, if a transmit frame-synchronization pulse is detected before McBSPi.MCBSPLP\_DXR\_REG is loaded, zeros are output on mcbspi\_dx.

The McBSPi.MCBSPLP\_IRQSTATUS\_REG[11] XUNDLSTAT bit indicates a real underflow condition, in which the frame is corrupted due to lack of data availability during transmit process. According to the McBSPi.MCBSPLP\_IRQENABLE\_REG register settings this condition can generate the McBSPi\_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP\_IRQSTATUS\_REG register clears the interrupt.

#### **23.5.4.10.6 Unexpected Transmit Frame-sync Pulse**

##### **23.5.4.10.6.1 Possible Responses to Transmit Frame-sync Pulses**

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-synchronization pulse, and the transmitter sets the transmit frame-synchronization error bit McBSPi.MCBSPLP\_IRQSTATUS\_REG[7] XSYNCERR (and the legacy McBSPi.MCBSPLP\_SPCR2\_REG[3] XSYNCERR bit).

According to the McBSPi.MCBSPLP\_IRQENABLE\_REG register settings, this condition can generate the McBSPi\_IRQ line to be asserted low. Writing 1 to the corresponding bit in status register clears the interrupt.

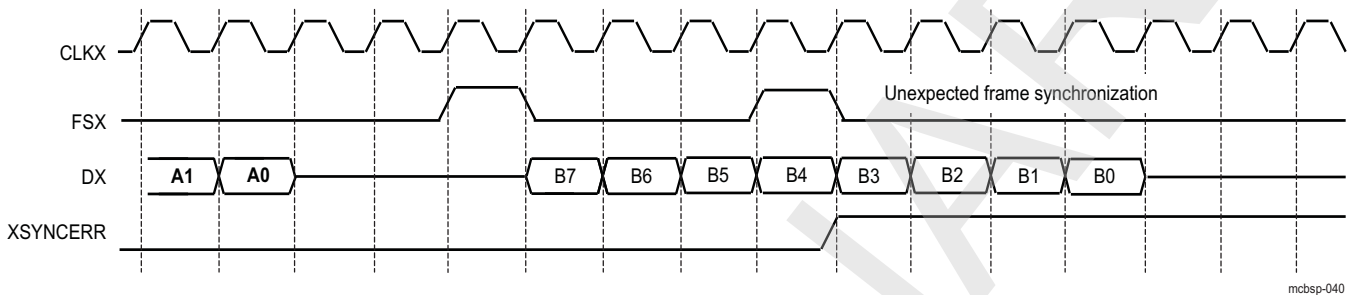

Using the legacy mode, McBSPi.MCBSPLP\_SPCR2\_REG[3] XSYNCERR bit can be cleared only by a transmitter reset or by a write of 0 to this bit. If you want the McBSP module to notify the MPU/DSP subsystem of frame-synchronization errors, you can set a special transmit interrupt mode with the McBSPi.MCBSPLP\_SPCR2\_REG[5:4] XINTM field. When XINTM=0b11, the McBSP module sends a transmit interrupt request to the MPU/DSP subsystem each time that XSYNCERR is set.

### 23.5.4.10.6.2 Example of Unexpected Transmit Frame-Synchronization Pulse

Figure 23-149 shows an unexpected transmit frame–synchronization pulse during normal operation of the serial port with intervals between the data packets.

**NOTE:** The unexpected transmit frame-synchronization pulse does not influence the data transmit process, being ignored by the data transmit state-machine.

**Figure 23-149. Unexpected Frame-sync Pulse During a McBSP Transmission**

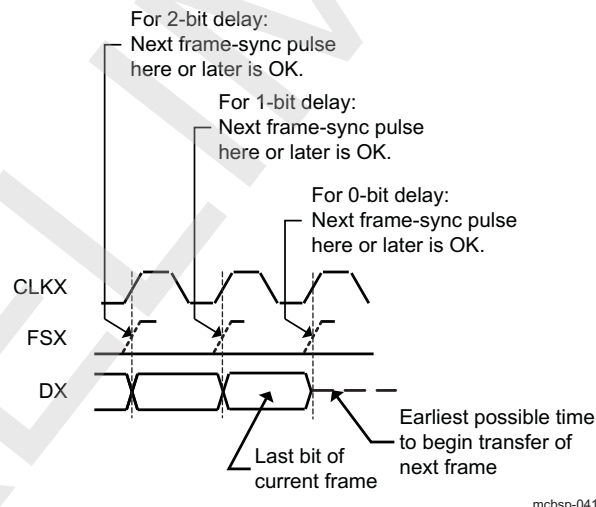

mcbasp-040

### 23.5.4.10.6.3 Preventing Unexpected Transmit Frame-sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKX cycles, depending on the value in the McBSPi.MCBSPLP\_XCR2\_REG[1:0] XDATDLY field. For each possible data delay, Figure 23-150 shows when a new frame–synchronization pulse on FSX can safely occur relative to the last bit of the current frame.

**Figure 23-150. Proper Positioning of Transmit Frame-sync Pulses**

mcbasp-041

### 23.5.4.10.7 Overflow in the Transmitter

The McBSP module indicates a transmitter overflow condition by setting the McBSPi.MCBSPLP\_IRQSTATUS\_REG[12] XOVLSTAT bit. This error occurs when sDMA controller or MPU/DSP subsystem write data to a full XB (this may happen only if the MPU/DSP subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request or does not check the buffer status before writing data). According to the McBSPi.MCBSPLP\_IRQENABLE\_REG register settings this condition can generate the McBSPi\_IRQ line to be asserted low. Writing 1 to the corresponding bit in status register clears the interrupt.

### 23.5.4.11 McBSP DMA Configuration

The McBSP receive and transmit data DMA requests are active after the receive McBSPi.MCBSPLP\_SPCR1\_REG[0] RRDY and transmit McBSPi.MCBSPLP\_SPCR2\_REG[0] XRDY are released. After reset the default DMA threshold (and length) is one.

The receive and transmit DMA requests can be individually disabled by setting the McBSPi.MCBSPLP\_RCCR\_REG[3] RDMAEN, McBSPi.MCBSPLP\_XCCR\_REG[3] XDMAEN bits to 0. When disabling the DMA, the DMA request line is de-asserted even if a DMA transfer is pending and the DMA state-machine is not reset.

The DMA threshold and length configuration is done through McBSPi.MCBSPLP\_THRSH1\_REG and McBSPi.MCBSPLP\_THRSH2\_REG registers as follows:

- (THRSH1\_REG + 1) value represents the required receive DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the RB occupied locations level is above or equal to the THRSH1\_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH1\_REG + 1) number of words, the receive DMA request is de-asserted and reasserted as soon as the conditions are met again.
- (THRSH2\_REG + 1) value represents the required transmit DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the XB free locations level is above or equal to the THRSH2\_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH2\_REG + 1) number of words, the transmit DMA request is de-asserted and reasserted as soon as the conditions are met again.

---

**NOTE:** The MPU/DSP subsystem can decide not to use the DMA to transfer the data. In this case, the DMA must be disabled (or the DMA request can be ignored by MPU/DSP subsystem) and the common interrupt line (MCBSPi\_IRQ) can be used. The McBSPi.MCBSPLP\_SPCR1\_REG[1] RRDY bit for receive and McBSPi.MCBSPLP\_SPCR2\_REG[1] XRDY bit for transmit will indicate when the threshold values are reached. Also, by reading the receive buffer status McBSPi.MCBSPLP\_RBUFFSTAT\_REG register and transmit buffer status McBSPi.MCBSPLP\_XBUFFSTAT\_REG register, the MPU/DSP subsystem can decide to transfer data even if the threshold is not reached. This mechanism is useful on the last transfer on receive side when the threshold value is bigger than the occupied locations inside the receive buffer and the MPU/DSP subsystem needs to read this data. Since no interrupt or DMA request is asserted the only option in this case is to read the RB status register value and to transfer the remaining data without using the DMA or interrupt indication.

---

### 23.5.4.12 Multi-channel Selection Modes

#### 23.5.4.12.1 Channels, Blocks and Partitions

A McBSP channel is a time slot for shifting in/out the bits of one serial word. The McBSP module supports up to 128 channels for reception and 128 channels for transmission. In the receiver and in the transmitter, the 128 available channels are divided into eight blocks that contain 16 contiguous channels each (see [Table 23-339](#)):

**Table 23-339. McBSP Channels**

<b>Block 0: Channels 0–15</b>	<b>Block 4: Channels 64–79</b>
<b>Block 1: Channels 16–31</b>	<b>Block 5: Channels 80–95</b>
<b>Block 2: Channels 32–47</b>	<b>Block 6: Channels 96–111</b>
<b>Block 3: Channels 48–63</b>	<b>Block 7: Channels 112–127</b>

The blocks are assigned to partitions according to the selected partition mode. In the two-partition mode described in [Section 23.5.4.12.6, Using Two Partitions \(Legacy Only\)](#), you assign one even-numbered block (0, 2, 4, or 6) to partition A and one odd-numbered block (1, 3, 5, or 7) to partition B. In the 8-partition mode, see [Section 23.5.4.12.4, Using Eight Partitions](#), blocks 0 through 7 are automatically assigned to partitions A through H, respectively.

The number of partitions for reception and the number of partitions for transmission are independent of each other. For example, it is possible to use two receive partitions (A and B) and eight transmit partitions (A–H).

### 23.5.4.12.2 Multi-channel Selection

When a McBSP module uses a time-division multiplexed (TDM) data stream while communicating with other McBSP modules or serial devices, the McBSP module may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, you can use a multi-channel selection mode to prevent data flow in some of the channels.

Each channel partition has a dedicated channel enable register. If the appropriate multi-channel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

The McBSP module has one receive multi-channel selection mode [Section 23.5.4.12.5, Receive Multi-channel Selection Mode](#) and three transmit multi-channel selection modes [Section 23.5.4.12.7, Transmit Multi-channel Selection Modes](#).

### 23.5.4.12.3 Configuring a Frame for Multi-channel Selection

Before enabling a multi-channel selection mode, make sure you properly configure the data frame:

- Select a single-phase frame (McBSPi.MCBSPLP\_RCR2\_REG[15] RPHASE bit and McBSPi.MCBSPLP\_XCR2\_REG[15] XPHASE bit=0). Each frame represents a TDM data stream.
- Set a frame length (in McBSPi.MCBSPLP\_RCR1\_REG[14:8] RFLEN1 field and in McBSPi.MCBSPLP\_XCR1\_REG[14:8] XFLEN1 field) that includes the highest-numbered channel to be used. For example, if you plan to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFLEN1=39). If XFLEN1=39 in this case, the receiver creates 40 time slots per frame but only receives data during time slots 0, 15, and 39 of each frame.

### 23.5.4.12.4 Using Eight Partitions

For multi-channel selection operation in the receiver and/or the transmitter, you can use eight partitions or two partitions (as previously described). If you choose the 8-partition mode (McBSPi.MCBSPLP\_MCR1\_REG[9] RMCME=1 for reception, McBSPi.MCBSPLP\_MCR2\_REG[9] XMCME=1 for transmission), McBSP channels are activated in the following order: A, B, C, D, E, F, G, H.

In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions in order until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred, beginning with the channels in partition A.

In the 8-partition mode, the McBSPi.MCBSPLP\_MCR1\_REG[6:5] RPABLK/McBSPi.MCBSPLP\_MCR2\_REG[6:5] XPABLK and McBSPi.MCBSPLP\_MCR1\_REG[8:7] RPBBLK/McBSPi.MCBSPLP\_MCR2\_REG[8:7] XPBBLK bits are ignored and the 16-channel blocks are assigned to the partitions as shown in [Table 23-340](#) through [Table 23-341](#). These assignments cannot be changed. The tables also show the registers used to control the channels in the partitions.

**Table 23-340. Eight Partitions – Receive Channel Assignment and Control**

Receive Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: channels 0 through 15	McBSPi.MCBSPLP_RCERA_REG
B	Block 1: channels 16 through 31	McBSPi.MCBSPLP_RCERB_REG
C	Block 2: channels 32 through 47	McBSPi.MCBSPLP_RCERC_REG
D	Block 3: channels 48 through 63	McBSPi.MCBSPLP_RCERD_REG
E	Block 4: channels 64 through 79	McBSPi.MCBSPLP_RCERE_REG
F	Block 5: channels 80 through 95	McBSPi.MCBSPLP_RCERF_REG
G	Block 6: channels 96 through 111	McBSPi.MCBSPLP_RCERG_REG
H	Block 7: channels 112 through 127	McBSPi.MCBSPLP_RCERH_REG

**Table 23-341. Eight Partitions – Transmit Channel Assignment and Control**

Transmit Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: channels 0 through 15	McBSPi.MCBSPLP_XCERA_REG
B	Block 1: channels 16 through 31	McBSPi.MCBSPLP_XCERB_REG
C	Block 2: channels 32 through 47	McBSPi.MCBSPLP_XCERC_REG
D	Block 3: channels 48 through 63	McBSPi.MCBSPLP_XCERD_REG
E	Block 4: channels 64 through 79	McBSPi.MCBSPLP_XCERE_REG
F	Block 5: channels 80 through 95	McBSPi.MCBSPLP_XCERF_REG
G	Block 6: channels 96 through 111	McBSPi.MCBSPLP_XCERG_REG
H	Block 7: channels 112 through 127	McBSPi.MCBSPLP_XCERH_REG

Figure 23-151 shows an example of the McBSP using the 8-partition mode. In response to a frame-synchronization pulse, the McBSP module begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128-word frame.

**Figure 23-151. McBSP Data Transfer in the 8-partition Mode**

#### 23.5.4.12.5 Receive Multi-channel Selection Mode

The McBSPi.MCBSPLP\_MCR1\_REG[0] RMCM bit determines whether all channels or only selected channels are enabled for reception.

- When RMCM=0, all 128 receive channels are enabled and cannot be disabled.
- When RMCM=1, the receive multi-channel selection mode is enabled. In this mode:
  - Channels can be individually enabled or disabled. The enabled channels are those selected in the appropriate receive channel enable registers (McBSPi.MCBSPLP\_RCERA\_REG/McBSPi.MCBSPLP\_RCERH\_REG). The channels are assigned to the McBSPi.MCBSPLP\_RCERA\_REG/McBSPi.MCBSPLP\_RCERH\_REG registers depends on the number of receive channel partitions (2 or 8), as defined by the McBSPi.MCBSPLP\_MCR1\_REG[9] RMCME bit.
  - If a receive channel is disabled, any bits received in that channel are not transferred to the RB, and as a result, the receiver ready bit (RRDY) is not set. Therefore, no DMA synchronization event is generated and, if the receiver interrupt mode depends on RRDY (McBSPi.MCBSPLP\_SPCR1\_REG[5:4] RINTM=0b00), no interrupt is generated.

As an example of how the McBSP module behaves in the receive multi-channel selection mode, suppose you enable only channels 0, 15, and 39 and that the frame length is 40. The McBSP module:

1. Accepts bits shifted in from the mcbspi\_dr pin in channel 0
2. Ignores bits received in channels 1–14
3. Accepts bits shifted in from the mcbspi\_dr pin in channel 15
4. Ignores bits received in channels 16–38
5. Accepts bits shifted in from the mcbspi\_dr pin in channel 39

#### 23.5.4.12.6 Using Two Partitions (Legacy Only)

For multi-channel selection operation in the receiver and/or the transmitter, you can use two partitions or eight partitions. If you choose the 2-partition mode (McBSPi.MCBSPLP\_MCR1\_REG[9] RMCME=0 for

reception, McBSPi.MCBSPLP\_MCR2\_REG[9] XMCME=0 for transmission), McBSP channels are activated using an alternating scheme. In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred beginning with the channels in partition A.

For reception, any two of the eight receive-channel blocks can be assigned to receive partitions A and B, which means up to 32 receive channels can be enabled at any given point. Similarly, any two of the eight transmit-channel blocks (up to 32 enabled transmit channels) can be assigned to transmit partitions A and B.

For reception:

- Assign an even-numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the McBSPi.MCBSPLP\_MCR1\_REG[6:5] RPABLK field. In the receive multi-channel selection mode, the channels in this partition are controlled by receive channel enable register A (McBSPi.MCBSPLP\_RCERA\_REG).
- Assign an odd-numbered block (1, 3, 5, or 7) to receive partition B with the McBSPi.MCBSPLP\_MCR1\_REG[8:7] RPBBLK field. In the receive multi-channel selection mode, the channels in this partition are controlled by receive channel enable register B (McBSPi.MCBSPLP\_RCERB\_REG).

For transmission:

- Assign an even-numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the McBSPi.MCBSPLP\_MCR2\_REG[6:5] XPABLK fields. In one of the transmit multi-channel selection modes, the channels in this partition are controlled by transmit channel enable register A (McBSPi.MCBSPLP\_XCERA\_REG).
- Assign an odd-numbered block (1, 3, 5, or 7) to transmit partition B with the McBSPi.MCBSPLP\_MCR1\_REG[8:7] XPBBLK field. In one of the transmit multi-channel selection modes, the channels in this partition are controlled by transmit channel enable register B (McBSPi.MCBSPLP\_XCERB\_REG).

Figure 23-152 shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0–15 have been assigned to partition A, and channels 16–31 have been assigned to partition B. In response to a frame-synchronization pulse, the McBSP module begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

**Figure 23-152. Alternating Between Partitions A and B Channels**

#### 23.5.4.12.7 Transmit Multi-channel Selection Modes

The McBSPi.MCBSPLP\_MCR2\_REG[1:0] XMCM field determine whether all channels or only selected channels are enabled and unmasked for transmission. The McBSP module has three transmit multi-channel selection modes (XMCM=0b01, XMCM=0b10, and XMCM=0b11), which are described in Table 23-342.

**Table 23-342. Selecting a Transmit Multi-Channel Selection Mode with the XMCM Bit Field**

XMCM	Transmit Multi-Channel Selection Mode
0b00	No transmit multi-channel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.
0b01	All channels are disabled unless they are selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). If enabled, a channel in this mode is also unmasked. The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 channels or 128 channels are selectable in the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers.

**Table 23-342. Selecting a Transmit Multi-Channel Selection Mode with the XMCM Bit Field (continued)**

XMCM	Transmit Multi-Channel Selection Mode
0b10	All channels are enabled, but they are masked unless they are selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 channels or 128 channels are selectable in the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers.
0b11	This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate receive channel enable registers (McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG). Once enabled, they are masked unless they are also selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 channels or 128 channels are selectable in McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG registers and McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers.

As an example of how the McBSP module behaves in a transmit multi-channel selection mode, suppose that XMCM=0b01 (all channels disabled unless individually enabled) and that you have enabled only channels 0, 15, and 39. Suppose also that the frame length is 40. The McBSP module:

1. Shifts data to the mcbspi\_dx pin in channel 0
2. Places the mcbspi\_dx pin in the high impedance state in channels 1–14
3. Shifts data to the mcbspi\_dx pin in channel 15
4. Places the mcbspi\_dx pin in the high impedance state in channels 16–38
5. Shifts data to the mcbspi\_dx pin in channel 39

**23.5.4.12.7.1 Disabling/Enabling Versus Masking/Unmasking**

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed)
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

The definitions in [Table 23-343](#) explain the channel control options:

**Table 23-343. McBSP Channel Control Options**

<b>Enabled channel</b>	A channel that can begin transmission by passing data from the data transmit register (McBSPi.MCBSPLP_DXR_REG) to the XSR through XB.
<b>Masked channel</b>	A channel that cannot complete transmission. The mcbspi_dx pin is held in the high impedance state; data cannot be shifted out on the mcbspi_dx pin. In systems where symmetric transmit and receive provide software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention.
<b>Disabled channel</b>	A channel that is not enabled. A disabled channel is also masked. Because no DXR-to-XB copy occurs, the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit is not set. Therefore, no DMA synchronization event is generated, and if the transmit interrupt mode depends on XRDY (McBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM=00b), no interrupt is generated. The McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is not affected.
<b>Unmasked channel</b>	A channel that is not masked. Data in the XSR(s) is shifted out on the mcbspi_dx pin.

**23.5.4.12.7.2 Activity on McBSP Pins for Different Values of XMCM**

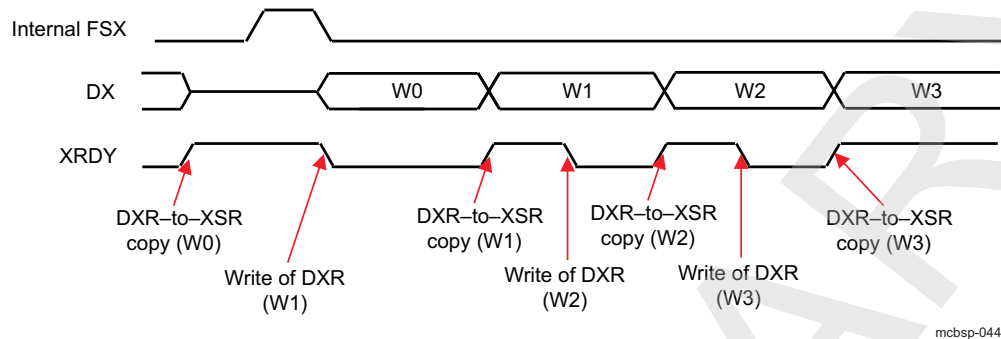

[Figure 23-153](#) shows the activity on the McBSP pins for the various McBSPi.MCBSPLP\_MCR2\_REG[1:0] XMCM values. In all cases, the transmit frame is configured as follows:

- XPHASE=0: Single-phase frame (required for multi-channel selection modes)
- XFRLLEN1=0b0000011: 4 words per frame
- XWDLEN1=0b000: 8 bits per word
- XMCME=0: 2-partition mode (only partitions A and B used)

In the case where McBSPi.MCBSPLP\_MCR2\_REG[1:0] XMCM=0b11, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLLEN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLLEN1, and XWDLEN1, respectively.

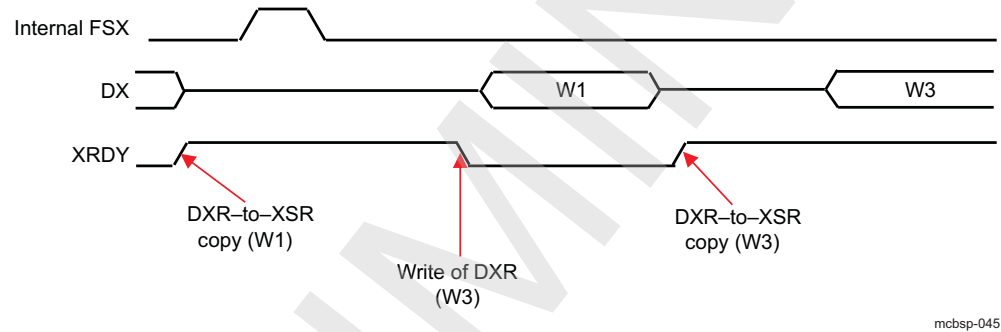

In [Figure 23-153](#), the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

**Figure 23-153. Activity on McBSP Pins When XMCM=0b00**

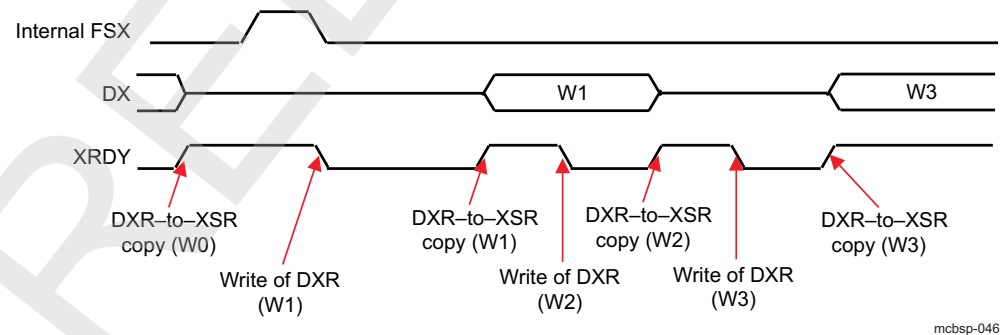

If XMCM = 0b00, all channels are enabled and unmasked. Words W0, W1, W2, and W3 are written to the XB, then, from the XB, there are transferred by mcbspi\_dx.

**Figure 23-154. Activity on McBSP Pins When XMCM=0b01**

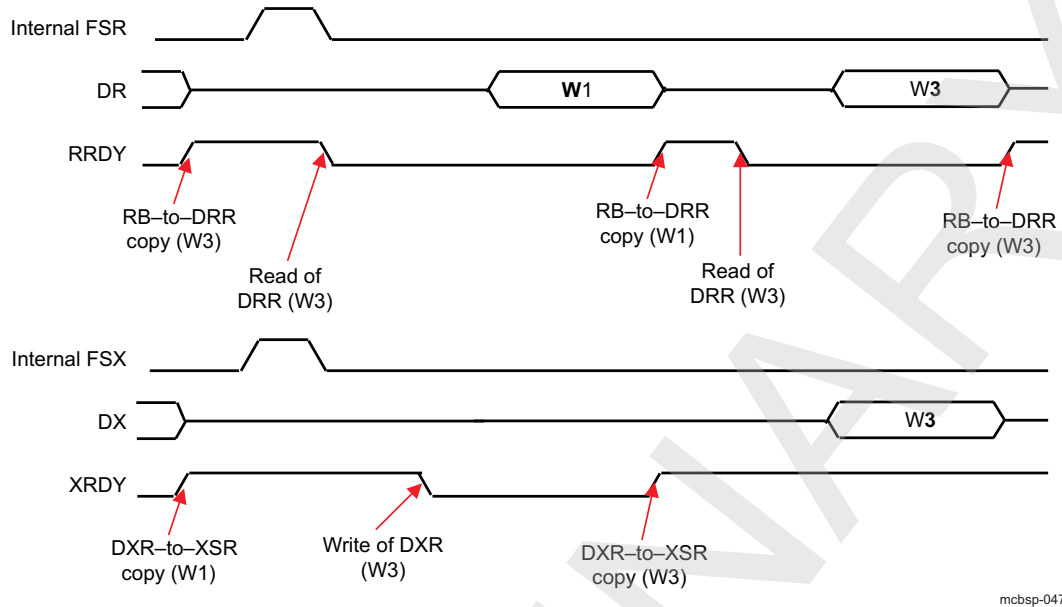

In [Figure 23-154](#) if XMCM = 0b01, XPABLK = 0b00, and XCERA = 0b1010, only channels 1 and 3 are enabled and unmasked. Words W1 and W3 are written to the XB, then, from the XB, there are transferred by mcbspi\_dx.

**Figure 23-155. Activity on McBSP Pins When XMCM=0b10**

In [Figure 23-155](#) if XMCM = 0b10, XPABLK = 0b00, and XCERA = 0b1010, all channels are enabled, only 1 and 3 unmasked. Words W0, W1, W2, and W3 are written to the XB, but only W1 and W3, from the XB, there are transferred by mcbspi\_dx.

Figure 23-156. Activity on McBSP Pins When XMCM=0b11

In Figure 23-156 if XMCM = 0b11, RPABLK = 0b00, XPABLK = 0bX, RCERA = 0b1010 and XCERA = 0b1000, channels 1 and 3 are enabled in receive and transmit mode, but only 3 unmasked. Words W1 and W3 are written to the XB, but only W3, from the XB, there are transferred by mcbspi\_dx.

### 23.5.5 McBSP Basic Programming Model

This section describes the programming model of typical McBSP module.

#### CAUTION

For all descriptions in this section, the McBSPi.MCBSPLP\_XCCR\_REG[11] XFULL\_CYCLE bit and the McBSPi.MCBSPLP\_RCCR\_REG[11] RFULL\_CYCLE bit are their reset value (XFULL\_CYCLE bit=0 and RFULL\_CYCLE bit=1).

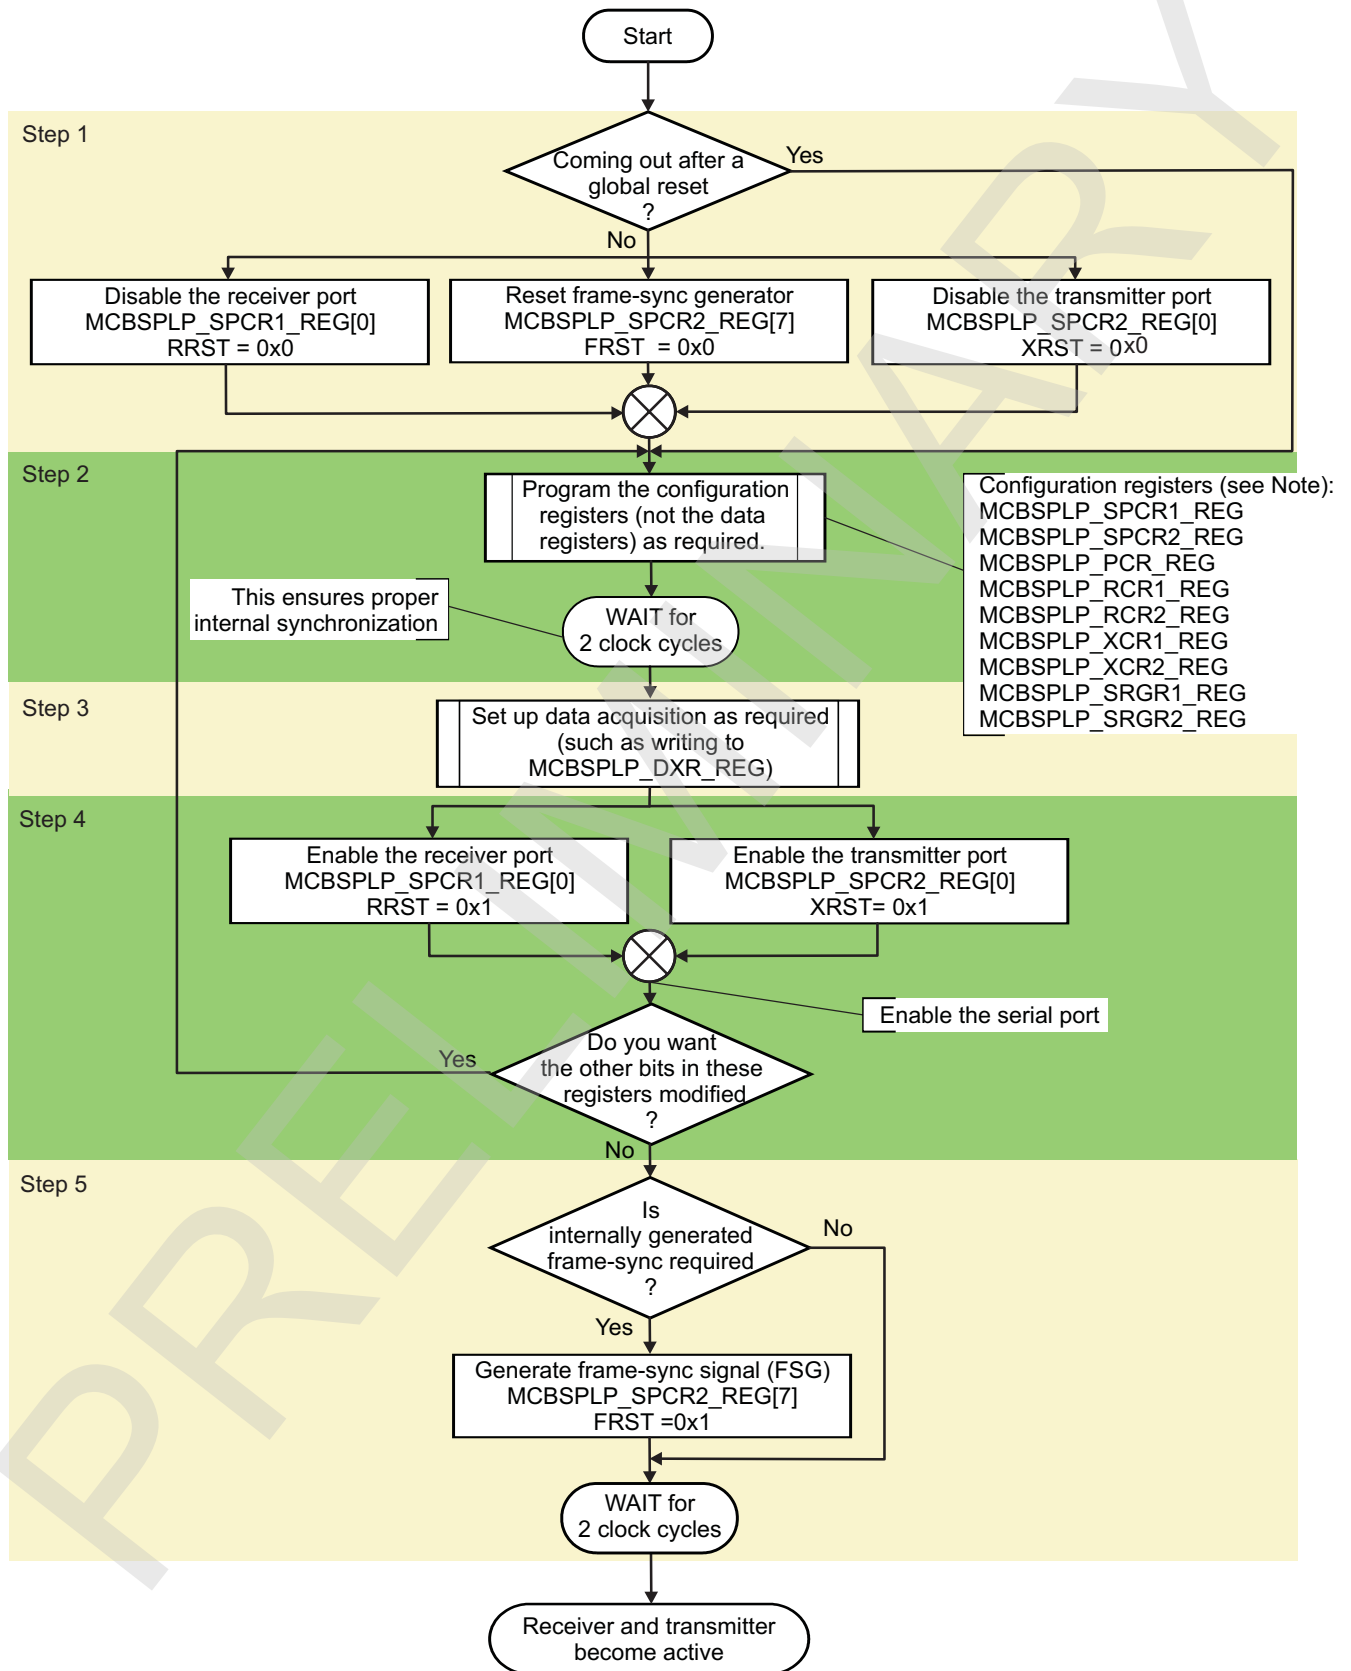

#### 23.5.5.1 McBSP Initialization Procedure

This procedure for reset/initialization can be applied in general when the Receiver or Transmitter has to be reset during its normal operation, and also when the Sample Rate Generator is not used for either operation.

Figure 23-157 presents the serial port initialization procedure for master mode.

Figure 23-157. Flow Diagram of McBSP Initialization Procedure for Master Mode

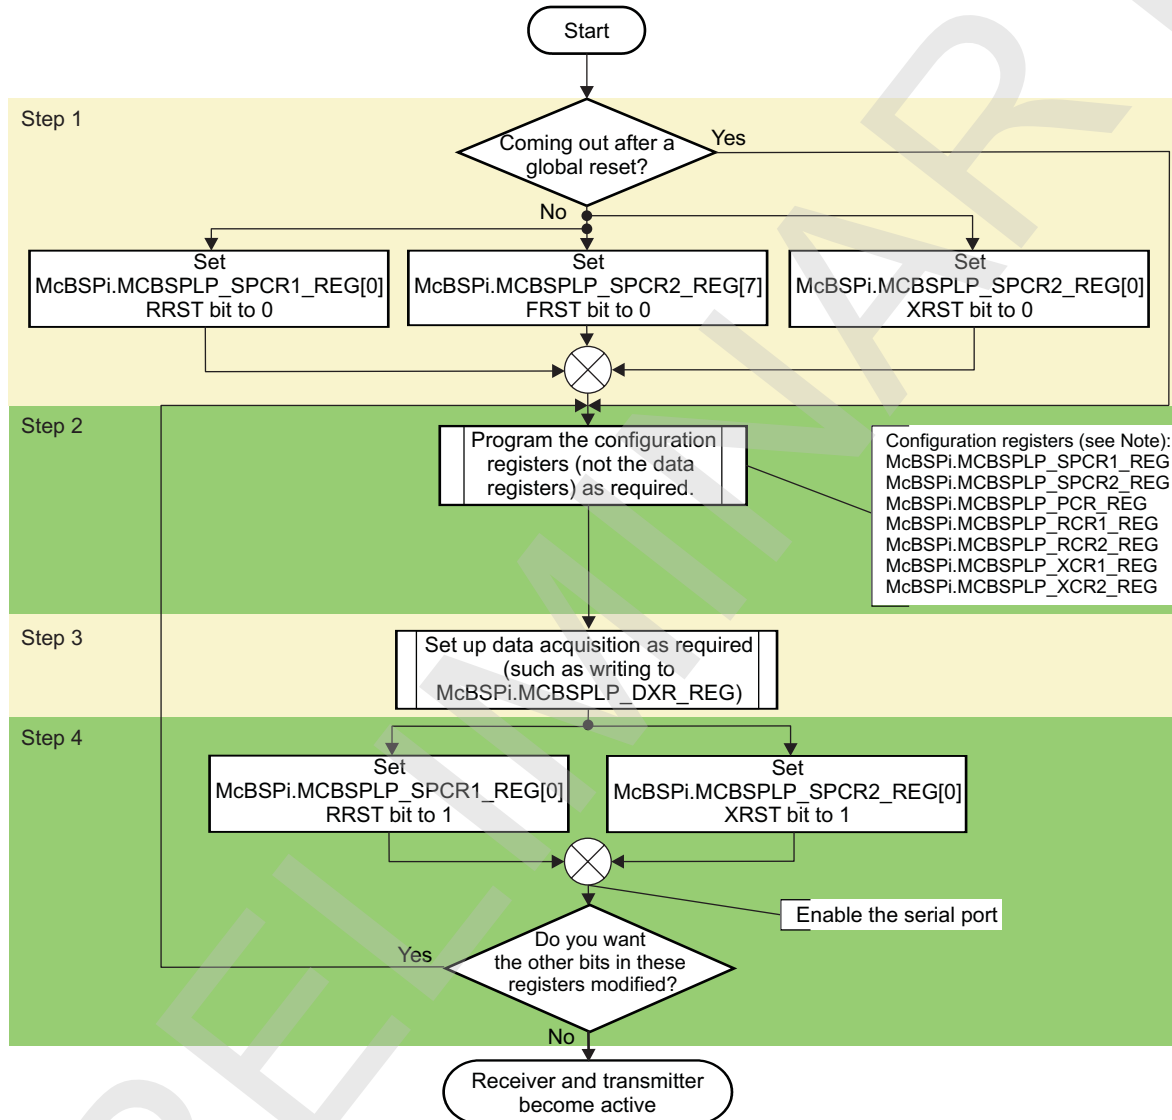

mcbsp-062

Alternatively, on write (step 1 or 4), the transmitter and receiver can be placed in or taken out of reset by modifying the McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST bit and the McBSPi.MCBSPLP\_SPCR1\_REG[0] RRST bit, respectively.

Figure 23-158 shows the flow diagram of the McBSP initialization procedure for slave mode.

**Figure 23-158. Flow Diagram of McBSP Initialization Procedure for Slave Mode**

mcbasp-075

**NOTE:**

- Alternatively, on write (step 1 or 4), the transmitter and receiver can be placed in or taken out of reset by modifying the McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST bit and the McBSPi.MCBSPLP\_SPCR1\_REG[0] RRST bit, respectively.
- The necessary duration of the active-low period of XRST or RRST is at least two CLKR/CLKX cycles.
- The appropriate bits in serial port configuration registers (McBSPi.MCBSPLP\_SPCR1\_REG, McBSPi.MCBSPLP\_SPCR2\_REG, McBSPi.MCBSPLP\_PCR\_REG, McBSPi.MCBSPLP\_RCR1\_REG, McBSPi.MCBSPLP\_RCR2\_REG, McBSPi.MCBSPLP\_XCR1\_REG, McBSPi.MCBSPLP\_XCR2\_REG, McBSPi.MCBSPLP\_THRSH2\_REG, McBSPi.MCBSPLP\_XCCR\_REG, McBSPi.MCBSPLP\_SYSCONFIG\_REG, McBSPi.MCBSPLP\_SRGR1\_REG and McBSPi.MCBSPLP\_SRGR2\_REG) should only be modified when the affected portion of the serial port is in its reset state.
- In most cases, the data transmit register (McBSPi.MCBSPLP\_DXR\_REG) should be loaded by the MPU/DSP subsystem or the sDMA controller only when the transmitter is enabled (McBSPi.MCBSPLP\_SPCR2\_REG[0] XRST = 1). An exception to this rule is when these registers are used for loopback internal data.
- The bits of the channel control registers (McBSPi.MCBSPLP\_MCR1\_REG, McBSPi.MCBSPLP\_MCR2\_REG, McBSPi.MCBSPLP\_RCER{A-H}\_REG and McBSPi.MCBSPLP\_XCER{A-H}\_REG) can be modified at any time as long as they are not being used by the current reception/transmission in a multichannel selection mode.
- The SRG is reset by setting McBSPi.MCBSPLP\_SPCR2\_REG[6] GRST bit to 0.
- It is not necessary to wait if SRG is not used
- The necessary duration of the active-low period of XRST or RRST is at least two
- Modification on-the-fly has no effect if a reset is not done first.

**Table 23-344. Register Call Summary for Flow Diagram of McBSP Initialization Procedure**

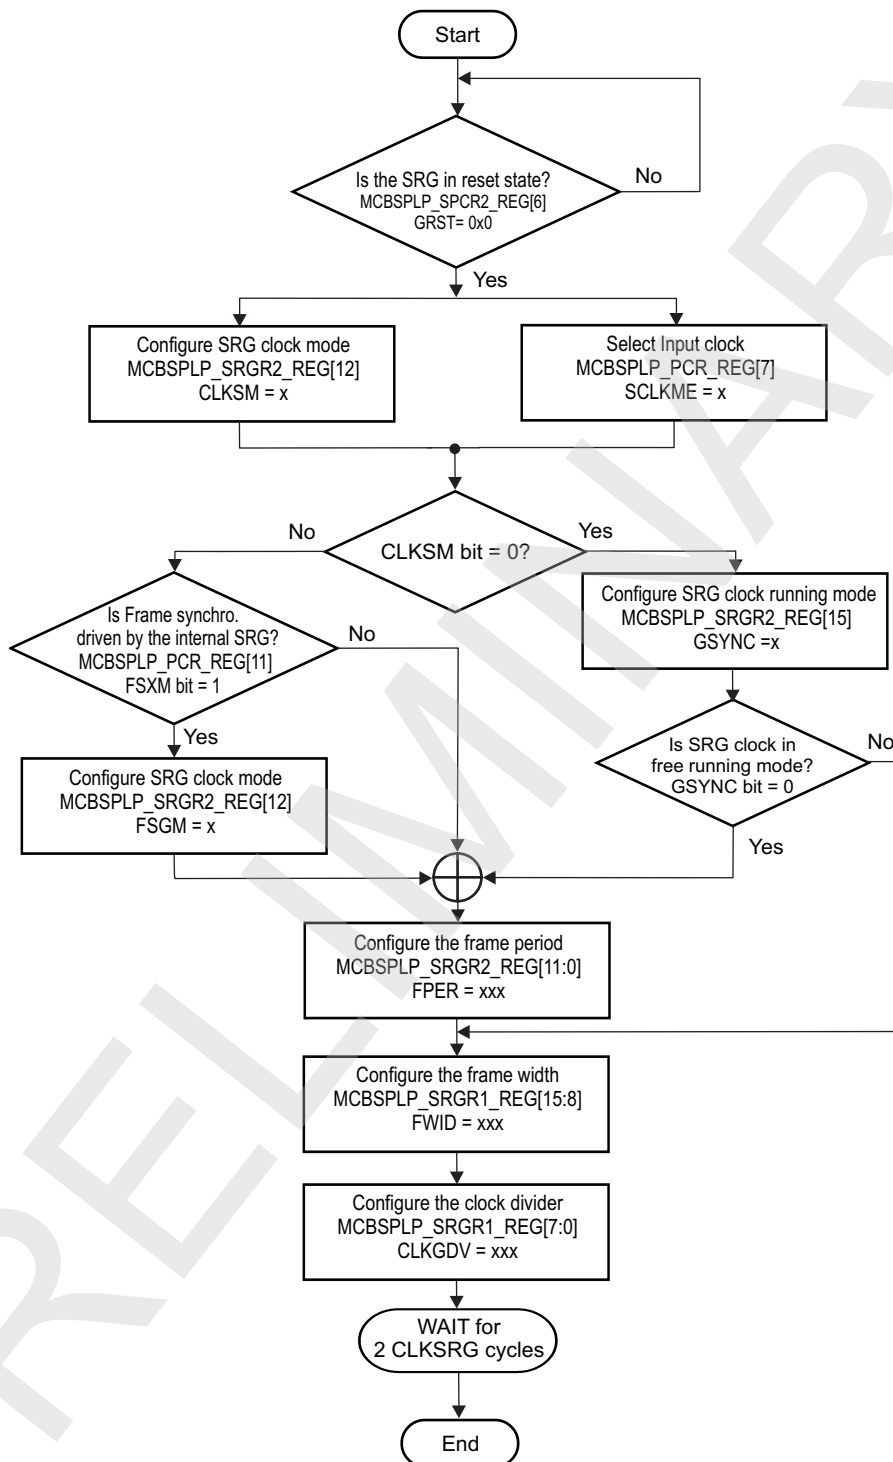

Register Name	Register Name	Register Name
MCBSPLP_SPCR1_REG	MCBSPLP_RCR1_REG	MCBSPLP_XCR2_REG
MCBSPLP_SPCR2_REG	MCBSPLP_RCR2_REG	MCBSPLP_SRGR1_REG
MCBSPLP_PCR_REG	MCBSPLP_XCR1_REG	MCBSPLP_SRGR2_REG

**23.5.5.2 Reset and Initialization Procedure for the Sample Rate Generator**

To reset and initialize the Sample Rate Generator:

- Place the McBSP Sample Rate Generator in RESET.
- Program the registers that affect the Sample Rate Generator.
- Enable the Sample Rate Generator (take it out of reset).
- If necessary, enable the receiver and/or the transmitter.
- If necessary, remove the receiver and/or transmitter from reset

Figure 23-159. Flow Diagram for the SRG Registers Programming

mcbsp-073

Table 23-345. Register Call Summary for Flow Diagram for the SRG Registers Programming

Register Name	Register Name
MCBSPLP_SPCR2_REG	MCBSPLP_PCR_REG
MCBSPLP_SRGR2_REG	MCBSPLP_SRGR1_REG

### 23.5.5.3 Data Transfer DMA Request Configuration

This procedure configures the McBSP receive/transmit data DMA requests (MCBSPi\_DMA\_RX and MCBSPi\_DMA\_TX).

**Table 23-346. Data Transfer DMA Request Configuration**

Step	Register / Bit Field / Programming Model	Value
Write the required receive DMA request length	MCBSPLP_THRSH1_REG[6:0] RTHRESHOLD	x..x
Write the required transmit DMA request length	MCBSPLP_THRSH2_REG[6:0] RTHRESHOLD	x..x

**NOTE:**

- The length of the transfer is the same as the threshold value + 1
- In case of a number of transfers that exceed the number of the programmed DMA length the McBSP module will respond to the command, and will perform the transfer regardless of the receive buffer empty condition.
- In case of a number of transfers that exceed the number of the programmed DMA length the McBSP module will respond to the command, and will perform the transfer regardless of the transmit buffer full condition.

### 23.5.5.4 Interrupt Configuration

This procedure configures the common receive/transmit interrupt request line.

**Table 23-347. Interruption Configuration**

Step	Register / Bit Field / Programming Model	Value
Enable the required IRQ events	MCBSPLP_IRQENABLE_REG	x..x

### 23.5.5.5 Receiver Configuration

To configure the McBSP receiver, perform the following steps:

- Step 1. Place the McBSP receiver in reset .
- Step 2. Program the McBSP registers for the desired receiver operation.
- Step 3. Take the receiver out of reset.

#### 23.5.5.5.1 Place the receiver in reset (Step 1)

**Table 23-348. Receiver Reset**

Step	Register / Bit Field / Programming Model	Value
Place the receiver in Reset	MCBSPLP_SPCR1_REG[0] RST	0x0

### 23.5.5.2 Programming the McBSP Registers for the Desired Receiver Configuration (Step 2)

Followings items detail important procedures to be performed when the software is configuring the McBSP receiver.

- **Global Configuration**

**Table 23-349. Global Configuration**

Step	Register / Bit Field / Programming Model	Value
Set the Receiver Pins to Operate as McBSP Pins	MCBSPLP_PCR_REG[12] RIOEN	0x0
Enable/ Disable the Digital Loop Back Mode <sup>(1)</sup>	MCBSPLP_XCCR_REG[5] DLB	0x0 or 0x1
Enable/ Disable the Analog Loop Back Mode <sup>(1)</sup>	MCBSPLP_SPCR1_REG[5] ALB	0x0 or 0x1
Select clock used in the synchronous transmit-receive mode (McBSP4 only) <sup>(1)</sup>	CONTROL_MCBSPLP[30] ALBCTRLRX_CLKX	0x0 or 0x1
Select Frame Synchronization used in the synchronous transmit-receive mode (McBSP4 only) <sup>(1)</sup>	CONTROL_MCBSPLP[31] ALBCTRLRX_FSX	0x0 or 0x1
Enable/ Disable the Receive Multichannel Selection Mode <sup>(1)</sup>	MCBSPLP_MCR1_REG[0] RMCN	0x0 or 0x1

<sup>(1)</sup> Software decision

**NOTE:** In digital Loopback mode the SRG and the Frame Synchronization generator need to be enabled to generate the CLKX and FSX signals.

- **Data Configuration**

**Table 23-350. Data Configuration**

Step	Register / Bit Field / Programming Model	Value
Select single/dual-phase frame <sup>(1)</sup>	MCBSPLP_RCR2_REG[15] RPHASE	0x0 or 0x1
Set the Receive Word Length(s) for Phase1 <sup>(1)</sup>	MCBSPLP_RCR1_REG[7:5] RWDLEN1	xxx
Set the Receive Word Length(s) for Phase2 <sup>(1)</sup>	MCBSPLP_RCR2_REG[7:5] XWDLEN2	xxx
Set the Receive Frame length*	MCBSPLP_RCR1_REG[14:8] RFRLEN1 MCBSPLP_RCR2_REG[14:8] RFRLEN2	xxx
Set the Receive Reverse Mode <sup>(1)</sup>	MCBSPLP_RCR2_REG[4:3] RREVERSE	xx
Set the Receive Data Delay <sup>(1)</sup>	MCBSPLP_RCR2_REG[1:0] RDATLY	xx
Set the Receive Sign-Extension and Justification Mode <sup>(1)</sup>	MCBSPLP_SPCR1_REG[14:13] RJUST	xx
Enable the serial Receiver Port	MCBSPLP_SPCR1_REG[0] RRST	0x1
Configure the Receive buffer threshold value <sup>(1)</sup>	MCBSPLP_THRSH1_REG[6:0] RTHRESHOLD	x..x

<sup>(1)</sup> Software decision

**NOTE:**

- When dual-phase is selected the number of words per phase must be set to one.
- If a single-phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame. If a dual-phase frame is selected, RWDLEN1 and RWDLEN2 must be set to select the both length. These both bits can have values different.
- If a dual-phase is selected, the frame length must be two words.

- **Frame-Sync Configuration**

**Table 23-351. Frame Sync Configuration**

Step	Register / Bit Field / Programming Model	Value
Set the Receive Frame-Sync Mode <sup>(1)</sup>	MCBSPLP_PCR_REG[10] FSRM	0x0 or 0x1
Select the Sample Rate Generator Synchronization <sup>(1)</sup>	MCBSPLP_SRGR2_REG[15] GSYNC	0x0 or 0x1
Set the Receive Frame-Sync Polarity <sup>(1)</sup>	MCBSPLP_PCR_REG[2] FSRP	0x0 or 0x1

<sup>(1)</sup> Software decision

**Table 23-351. Frame Sync Configuration (continued)**

Step	Register / Bit Field / Programming Model	Value
Set the SRG Frame-Sync Period <sup>(1)</sup>	MCBSPLP_SRGR2_REG[11:0] FPER	x..x
Set the SRG Frame-Sync Pulse Width <sup>(1)</sup>	MCBSPLP_SRGR1_REG[15:8] FWID	x..x

- **Clock Configuration**

**Table 23-352. Clock Configuration**

Step	Register / Bit Field / Programming Model	Value
Set the Receive Clock Mode <sup>(1)</sup>	MCBSPLP_PCR_REG[8] CLKRM	0x0 or 0x1
Set the Receive Clock Polarity <sup>(1)</sup>	MCBSPLP_PCR_REG[0] CLKRP	0x0 or 0x1
Set the SRG Clock Divide-Down Value <sup>(1)</sup>	MCBSPLP_SRGR1_REG[7:0] CLKGDV	x..x
Set the SRG Clock Synchronization Mode <sup>(1)</sup>	MCBSPLP_SRGR2_REG[15] GSYNC	0x0 or 0x1
Set the SRG Input Clock Mode <sup>(1)</sup>	MCBSPLP_PCR_REG[7] SCKLME MCBSPLP_SRGR2_REG[13] CLKSM	0x0 or 0x1
Set the SRG Input Clock Polarity <sup>(1)</sup>	MCBSPLP_SRGR2_REG[14] CLKSP MCBSPLP_PCR_REG[1] CLKXP MCBSPLP_PCR_REG[0] CLKRP	0x0 or 0x1

<sup>(1)</sup> Software decision

**NOTE:** CLKRP=CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

### 23.5.5.5.3 Take the Receiver Out of Reset (Step 3)

**Table 23-353. Take the Receiver Out of Reset**

Step	Register / Bit Field / Programming Model	Value
Enable the receiver	MCBSPLP_SPCR1_REG[0] RST	0x1

### 23.5.5.6 Transmitter Configuration

To configure the McBSP transmitter, perform the following steps:

- Step 1. Place the McBSP transmitter in reset
- Step 2. Program the McBSP registers for the desired transmitter operation
- Step 3. Take the transmitter out of reset

#### 23.5.5.6.1 Place the Transmitter in Reset (Step 1)

**Table 23-354. Transmitter Reset**

Step	Register / Bit Field / Programming Model	Value
Place the transmitter in Reset	MCBSPLP_SPCR2_REG[0] RST	0x0

#### 23.5.5.6.2 Programming the McBSP Registers for the Desired Transmitter Operation (Step 2)

Followings items detail important procedures to be performed when the software is configuring the McBSP transmitter.

- **Global Configuration**

**Table 23-355. Global Configuration**

Step	Register / Bit Field / Programming Model	Value
Set the transmitter Pins to Operate as McBSP Pins	MCBSPLP_PCR_REG[13] XIOEN	0x0
Enable/ Disable the Digital Loop Back Mode <sup>(1)</sup>	MCBSPLP_XCCR_REG[5] DLB	0x0 or 0x1
Enable/ Disable the Analog Loop Back Mode <sup>(1)</sup>	MCBSPLP_SPCR1_REG[5] ALB	0x0 or 0x1
Select clock used in the synchronous transmit-receive mode (McBSP4 only) <sup>(1)</sup>	CONTROL_MCBSPLP[30] ALBCTRLRX_CLKX	0x0 or 0x1
Select Frame Synchronization used in the synchronous transmit-receive mode (McBSP4 only) <sup>(1)</sup>	CONTROL_MCBSPLP[31] ALBCTRLRX_FSX	0x0 or 0x1
Enable/ Disable the Transmit Multichannel Selection Mode <sup>(1)</sup>	MCBSPLP_MCR1_REG[0] RCMCM	0x0 or 0x1

<sup>(1)</sup> Software decision

- **Data Configuration**

**Table 23-356. Data Configuration**

Step	Register / Bit Field / Programming Model	Value
Select single/dual-phase frame <sup>(1)</sup>	MCBSPLP_RCR2_REG[15] XPHASE	0x0 or 0x1
Set the Transmit Word Length(s) for Phase1 <sup>(1)</sup>	MCBSPLP_XCR1_REG[7:5] XWDLEN1	xxx
Set the Transmit Word Length(s) for Phase2 <sup>(1)</sup>	MCBSPLP_XCR2_REG[7:5] XWDLEN2	xxx
Set the Transmit Frame length <sup>(1)</sup>	MCBSPLP_XCR1_REG[14:8] XFRLEN1 MCBSPLP_XCR2_REG[14:8] XFRLEN2	xxx
Set the Transmit Reverse Mode <sup>(1)</sup>	MCBSPLP_XCR2_REG[4:3] XREVERSE	xx
Set the Transmit Data Delay <sup>(1)</sup>	MCBSPLP_XCR2_REG[1:0] XDATLY	xx
Set the extra delay (DX delay) mode <sup>(1)</sup>	MCBSPLP_SPCR1_REG[7] DXENA	xx
Select the inserted delay value <sup>(1)</sup>	MCBSPLP_XCCR_REG[13:12] DXENDLY	xx
Set the Interrupt Line	MCBSPLP_IRQENABLE_REG	x..x
Configure the Transmit buffer threshold value <sup>(1)</sup>	MCBSPLP_THRSH2_REG[6:0] XTHRESHOLD	x..x

<sup>(1)</sup> Software decision**NOTE:**

- When dual-phase is selected the number of words per phase must be set to one.
- If a single-phase frame is selected, XWDLEN1 selects the length for every serial word transmit in the frame. If a dual-phase frame is selected, XWDLEN1 and XWDLEN2 must be set to select the both length. These both bits can have values different.
- If a dual-phase is selected, the frame length must be two words.

The DXENA bit controls the delay enabler on the mcbasp\_dx pin. Set DXENA to enable an extra delay for turn-on time. Because this bit does not control the data itself, only the first bit is delayed (the delay is given by a combinatorial delay buffer). The inserted delay, 80 ps, 160 ps (default), 240 ps, or 320 ps, can be set using the McBSPi.MCBSPLP\_XCCR\_REG[13:12] DXENDLY bit field. If the mcbasp\_dx pins of multiple McBSP modules are tied together, ensure that DXENA = 1 to avoid having more than one McBSP transmitting at a time on the data line.

- **Frame-Sync Configuration**

**Table 23-357. Frame-Synchronization Configuration**

Step	Register / Bit Field / Programming Model	Value
Set the Transmit Frame-Sync Mode <sup>(1)</sup>	MCBSPLP_PCR_REG[11] FSXM MCBSPLP_SRGR2_REG[12] FSGM	0x0 or 0x1
Set the Transmit Frame-Sync Polarity <sup>(1)</sup>	MCBSPLP_PCR_REG[3] FSXP	0x0 or 0x1
Set the SRG Frame-Sync Period <sup>(1)</sup>	MCBSPLP_SRGR2_REG[11:0] FPER	x..x
Set the SRG Frame-Sync Pulse Width <sup>(1)</sup>	MCBSPLP_SRGR1_REG[15:8] FWID	x..x

<sup>(1)</sup> Software decision

- **Clock Configuration**

**Table 23-358. Clock Configuration**

Step	Register / Bit Field / Programming Model	Value
Set the Transmit Clock Mode <sup>(1)</sup>	MCBSPLP_PCR_REG[9] CLKXM	0x0 or 0x1
Set the Transmit Clock Polarity <sup>(1)</sup>	MCBSPLP_PCR_REG[1] CLKXP	0x0 or 0x1
Set the SRG Clock Divide-Down Value <sup>(1)</sup>	MCBSPLP_SRGR1_REG[7:0] CLKGDV	x..x
Set the SRG Clock Synchronization Mode <sup>(1)</sup>	MCBSPLP_SRGR2_REG[15] GSYNC	0x0 or 0x1
Set the SRG Input Clock Mode <sup>(1)</sup>	MCBSPLP_PCR_REG[7] SCKLME MCBSPLP_SRGR2_REG[13] CLKSM	0x0 or 0x1
Set the SRG Input Clock Polarity <sup>(1)</sup>	MCBSPLP_SRGR2_REG[14] CLKSP MCBSPLP_PCR_REG[1] CLKXP MCBSPLP_PCR_REG[0] CLKRP	0x0 or 0x1

<sup>(1)</sup> Software decision

**NOTE:** CLKRP=CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

### 23.5.5.6.3 Take the receiver out of reset (Step 3)

**Table 23-359. Take the Receiver Out of Reset**

Step	Register / Bit Field / Programming Model	Value
Enable the transmitter	MCBSPLP_SPCR2_REG[0] RST	0x1

### 23.5.5.7 General-Purpose I/O on the McBSP Pins (Legacy Only)

To use McBSP pins as general-purpose I/O pins rather than as serial port pins, follow these steps:

- **For the receive pins (mcbasp\_clkr, mcbasp\_fsr, and mcbasp\_dr as)**

**Table 23-360. Use Serial Receive Pins as GPIO Pins**

Step	Register / Bit Field / Programming Model	Value
Place the receiver in Reset	MCBSPLP_SPCR1_REG[0] RRST	0x0
Enabled GPIO for the serial port receiver	MCBSPLP_PCR_REG[12] RIOEN	0x1

- **For the transmitter pins (mcbasp\_clkx, mcbasp\_fsx, and mcbasp\_dx)**

**Table 23-361. Use Serial Transmit Pins as GPIO Pins**

Step	Register / Bit Field / Programming Model	Value
Place the transmit in Reset	MCBSPLP_SPCR2_REG[0] XRST	0x0
Enabled GPIO for the serial port transmitter	MCBSPLP_PCR_REG[12] XIOEN	0x1

- **For the external clock pins (mcbasp\_clks)**

For the mcbasp\_clks pin (common to all McBSP modules), all of the reset and I/O conditions must be met as follow:

**Table 23-362. Use External Clock Pin as GPIO Pin**

Step	Register / Bit Field / Programming Model	Value
Place the receiver in Reset	MCBSPLP_SPCR1_REG[0] RRST	0x0
Place the transmit in Reset	MCBSPLP_SPCR2_REG[0] XRST	0x0
Enabled GPIO for the serial port receiver	MCBSPLP_PCR_REG[12] RIOEN	0x1
Enabled GPIO for the serial port transmitter	MCBSPLP_PCR_REG[12] XIOEN	0x1

### 23.5.6 MCBSP Register Manual

Table 23-363 shows the base address and address space for the device module instances.

#### 23.5.6.1 MCBSP Instance Summary

**Table 23-363. MCBSP Instance Summary**

Module Name	Base Address L3 Interconnect	Base Address Cortex-A9 Private Access	Base Address DSP Private Access	Base Address L4-PER Interconnect	Size
MCBSP1	0x4902 2000	0x4012 2000	0x2 2000	N/A	4KB
MCBSP2	0x4902 4000	0x4012 4000	0x2 4000	N/A	4KB
MCBSP3	0x4902 6000	0x4012 6000	0x2 6000	N/A	4KB
MCBSP4	N/A	N/A	N/A	0x4809 6000	4KB

**NOTE:** Private Access is an access which is not using the L3/L4 interconnects.

#### 23.5.6.2 MCBSP Registers

##### CAUTION

The McBSP registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

##### 23.5.6.2.1 MCBSP Register Summary

**Table 23-364. MCBSP1 Register Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address L3 Interconnect	Physical Address Cortex-A9 Private Access	Physical Address DSP Private Access
MCBSPLP_DRR_REG	R	32	0x0000 0000	0x4902 2000	0x4012 2000	0x2 2000

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0000
15	EXTCLKGATE	External clock gating enable (CLKX and FSX master only). When this bit is set and the transmit clock and FSX are set as output, the CLKX is enabled when FSX is active plus 3 clock cycles after (clock is provided for FWID + 4 clock cycles, assuming that the FSX width, active, is FWID + 1 clock cycles); outside this window the external transmit clock is gated. The receive use the same gated transmit clock and transmit frame synchronization signals regardless of the CLKRM/FSRM settings. When using this mode the frame synchronization signal must be active during reception of the entire frame (FWID must be programmed accordingly) to ensure the proper receive process, which requires at least 3 cycles after the frame complete to transfer the data into the receive buffer. 0x0: External clock gating disabled. 0x1: External clock gating enable.	RW	0
14	PPCONNECT	Pair to pair connection. When set the DXENO pin is always set to 0 regardless of the frame boundary, setting the tree state buffer as output 0x0: Pair to pair connection. When set the DXENO pin is always set to 0 regardless of the frame boundary, setting the tree state buffer as output 0x1: Pair to pair connection. When set the DXENO pin is always set to 0 regardless of the frame boundary, setting the tree state buffer as output	RW	0

## 23.6 Multichannel PDM Controller

### 23.6.1 McPDM Overview

The multichannel pulse density modulation (McPDM) module consists in a proprietary audio module dedicated to mobile phone terminals. It is composed of audio uplink and downlink paths communicating with an external audio companion chip through a dedicated interface.

Figure 23-160 is an overview of the McPDM module.

The McPDM module can support the following features:

- Full duplex communication:
  - Five audio downlink channels with up to 3.84 Mbps each
  - Three audio uplink channels with up to 3.84 Mbps each
  - One command channel with up to 3.84 Mbps
  - One status channel with up to 3.84 Mbps
- Uplink and downlink first in first out (FIFO) operations:
  - 16 x 96-bit words for FIFO uplink, where a 96-bit word contains three 24-bit words for the audio uplink channels (one 24-bit word per audio uplink channel) and one 16-bit word for status information.
  - 16 x 144-bit words for FIFO downlink, where a 144-bit word contains five 24-bit words for the audio downlink channels (one 24-bit word per audio downlink channel) and one 16-bit word for the command data.
- Interrupt request to microprocessor unit (MPU) and digital signal processor (DSP) subsystems
- Direct memory access (DMA) requests with programmable FIFO thresholds:
  - One DMA request for downlink path
  - One DMA request for uplink path
- Up-sampling and pulse-density modulators for each audio downlink channel (five channels)
- Offset cancellation feature for audio downlink channels 1 and 2
- Decimation filter and downsampling for each audio uplink channel (three channels)
- Idle state hardware handshake

- Wake-up request

### 23.6.2 McPDM Environment

This section describes the McPDM application fields from an environment point of view (external connections). It describes McPDM connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

#### 23.6.2.1 McPDM Modes

Table 23-454 describes the modes and application fields of the McPDM module.

**Table 23-454. Modes**

Mode	Description
Normal mode	Up to five audio channels are transmitted to, and up to three audio channels are received from, the audio companion chip.
Command mode	In addition to the audio channels, commands are transmitted to the audio companion chip.
Status mode	In addition to the audio channels, status information is received from the audio companion chip.

#### 23.6.2.2 McPDM Signals

Table 23-455 describes the McPDM module signals and specifies their links to modes.

**Table 23-455. I/O**

Signal	I/O (1)	Description	Reset Value	Normal Mode	Command Mode	Status Mode
abe_clks	I	Clock received from the audio companion chip. The clock frequency is: <ul style="list-style-type: none"> <li>• 17.64 MHz for a sampling frequency of 88.2/176.4 kHz</li> <li>• 19.2 MHz for a sampling frequency of 96/192 kHz</li> </ul>	-	x	x	x
abe_pdm_lb_clk	O	Clock loop-back to the audio companion chip from the abe_clks clock signal. The frequency is the same as abe_clks frequency	0	x	x	x
abe_pdm_frame	I/O	Frame synchronization and command/status data.	0	x	x	x
abe_pdm_ul_data	I	Audio uplink path data.	-	x	x	x
abe_pdm_dl_data	O	Audio downlink path data.	0	x	x	x

(1) I = Input; O = Output

### 23.6.2.3 McPDM Configurations

Figure 23-161 shows the McPDM generic configuration.

Figure 23-161. McPDM Generic Configuration

mcpdm-002

### 23.6.2.4 Protocols and Data Formats

#### 23.6.2.4.1 Protocols and Data Formats in Normal Mode

This section describes data transfer on the interface in normal mode. In this mode, the `abe_pdm_frame` signal is only used for frame synchronization purposes. Figure 23-162 shows the protocols and data formats in normal mode for two examples:

- (a) With two downlink and three uplink channels enabled
- (b) With five downlink and three uplink channels enabled

Figure 23-162. Protocols and Data Formats in Normal Mode

a) Normal mode with 2 downlink and 3 uplink channels enabled

b) Normal mode with 5 downlink and 3 uplink channels enabled

mcpdm-003

In normal mode, the frequency ratio between the `abe_pdm_frame` and `abe_pdm_lb_clk` signals is 10. This ratio is static and the `abe_pdm_frame` signal low-pulse width is one clock period longer than the `abe_pdm_lb_clk` signal.

The `abe_pdm_frame` signal is driven by the McPDM module in the device to the external audio companion chip. The McPDM module drives the `abe_pdm_frame` signal low during one clock period of the `abe_pdm_lb_clk` signal, then it drives it high during one clock period of the `abe_pdm_lb_clk` signal before releasing the `abe_pdm_frame` I/O driver in high-impedance state. The McPDM module pad internal pull-up resistor allows keeping a high-level state on the `abe_pdm_frame` line when the `abe_pdm_frame` I/O driver is in high-impedance state.

A maximum of two samples  $\times$  five downlink channels (10 samples) can be transmitted by the McPDM module to the external audio companion chip during a frame period.

A maximum of two samples  $\times$  three uplink channels (six samples) can be received by the McPDM module from the external audio companion chip during a frame period.

Each downlink and uplink channel can be independently enabled or disabled by setting to 1 or clearing to 0 the corresponding bit in the `MCPDM_CTRL` register.

#### 23.6.2.4.2 Protocols and Data Formats in Command Mode

This section describes data transfer on the interface in command mode. In this mode, the `abe_pdm_frame` signal is used to transmit command words to the external audio companion chip. It allows configuring audio registers in the external audio companion chip (that is, amplifier gains) without using the legacy inter-integrated circuit (I<sup>2</sup>C™) interface, which could be busy and add latency to gain correction.

---

**NOTE:** In command mode, uplink channel samples are transmitted to and downlink channel samples are received from the external audio companion chip as in normal mode.

---

Figure 23-163 shows the protocols and data formats in command mode.

**Figure 23-163. Protocols and Data Formats in Command Mode**

##### 23.6.2.4.2.1 Entering the Command Mode

Command mode can be entered when command data are pending and no status mode is ongoing or detected.

If both of these conditions are met and the `MCPDM_CTRL`[9] `CMD_INT` bit is set to 1, the McPDM module automatically enters the command mode.

To enter the command mode, the McPDM module must drive the `abe_pdm_frame` signal low during two periods of the `abe_pdm_lb_clk` clock signal.

The external audio companion chip detects a command mode request from the McPDM module when a low state has been detected during two periods of the `abe_pdm_lb_clk` clock signal. Once a command mode request is detected, the external audio companion chip enters the command mode. In this mode, the status mode cannot be entered during at least four frame cycles.

If a status mode is detected or ongoing while a command is ready to be sent, the command data are stored in an internal register.

If one or more command data are written before the previous one is sent, the previous one is overwritten with the new one and only the last stored 16-bit command data are sent.

If a new command data are available while the system is already in command mode, the current command completes normally and exits before re-entering the command mode and transmitting the new command data a frame period later.

#### **23.6.2.4.2.2 Command Data Transmission**

The 16-bit command data are transmitted directly after the `abe_pdm_frame` signal is driven low during two periods of the `abe_pdm_lb_clk` clock signal.

When the `MCPDM_CTRL[9]` `CMD_INT` bit is set to 1, 16-bit command data must be written to the `MCPDM_DN_DATA` register. Only the 16 lower bits are significant. When no command must be transmitted on the `abe_pdm_frame` line, a null word (0x00000000) must be written as the command data.

When the `MCPDM_CTRL[9]` `CMD_INT` bit is cleared to 0, no 16-bit command data has to be written to the `MCPDM_DN_DATA` register.

#### **23.6.2.4.2.3 Exiting the Command Mode**

After the 16-bit command data has been sent, the McPDM module drives the `abe_pdm_frame` signal high during one period of the `abe_pdm_lb_clk` clock signal before releasing the `abe_pdm_frame` I/O driver in high-impedance state. The McPDM module pad internal pullup resistor allows keeping a high-level state on the `abe_pdm_frame` line when the `abe_pdm_frame` I/O driver is in high-impedance state.

The McPDM module exits automatically from command mode one period of the `abe_pdm_lb_clk` clock signal after the last bit of the command data has been transmitted on the `abe_pdm_frame` line.

---

**NOTE:** Due to this protocol mechanism, frame synchronization is lost (replaced by the ninth bit of the command data) during one frame period. The external audio companion chip must internally emulate a frame synchronization to send uplink channel samples and received downlink channel samples as in normal mode while receiving command data on the `abe_pdm_frame` line.

---

#### **23.6.2.4.2.4 Multiple Command Data Access**

As shown in [Figure 23-163](#), two consecutive command data can be sent every three frames. If no status mode is entered after a command data has been sent, the next command data is sent three frames after starting to send the current command data.

#### **23.6.2.4.3 Protocols and Data Formats in Status Mode**

This section describes data transfer on the interface in status mode. In this mode, the `abe_pdm_frame` signal is used to receive status information from the external audio companion chip.

---

**NOTE:** In status mode, uplink channel samples are transmitted to and downlink channel samples are received from the external audio companion chip as in normal mode.

---

Figure 23-164 shows the protocols and data formats in status mode.

**Figure 23-164. Protocols and Data Formats in Status Mode**

mcpdm-005

#### **23.6.2.4.3.1 Entering the Status Mode**

Status mode can be entered when no command mode is detected during the last frame low pulse and no command mode is ongoing.

If both of these conditions are met and the `MCPDM_CTRL[10]` `STATUS_INT` bit is set to 1, the McPDM module automatically enters the status mode when the command mode is complete.

In status mode, the status information data are sent by the external audio companion chip to the McPDM module. The status information is stored in an internal register.

If one or more status information packages are received before the previous status information has been read, the status information stored in the internal register is overwritten with the new one.

In status mode, the external audio companion chip drives the `abe_pdm_frame` line low until the next frame synchronization low pulse. Then, it sends the 16-bit status information data on the `abe_pdm_frame` line. During the transmission of the status information, the McPDM module does not generate any frame synchronization low pulse on the `abe_pdm_frame` line for one frame period.

#### **23.6.2.4.3.2 Status Information Data Reception**

The 16-bit status information data are received directly after the second frame synchronization low pulse on the `abe_pdm_frame` line.

When the `MCPDM_CTRL[10]` `STATUS_INT` bit is set to 1, 16 bits of status information data must be read from the `MCPDM_UP_DATA` register. Only the 16 lower bits are significant. When the value of the status information is a null word (0x00000000), it means that no status information has been sent by the external audio companion chip.

When the `MCPDM_CTRL[10]` `STATUS_INT` bit is cleared to 0, no status information data has to be read from the `MCPDM_UP_DATA` register.

#### **23.6.2.4.3.3 Exiting the Status Mode**

After the 16-bit status information data has been sent, the external audio companion chip drives the `abe_pdm_frame` line high during one period of the `abe_pdm_lb_clk` clock signal before releasing its I/O driver in high-impedance state.

The McPDM module automatically exits the status mode one period of the `abe_pdm_lb_clk` clock signal after the last bit of the status information data has been transmitted on the `abe_pdm_frame` line. After exiting the status mode, the McPDM module generates frame synchronization low pulses.

---

**NOTE:** Due to the protocol mechanism, frame synchronization is lost during three frame periods. The external audio companion chip must internally emulate a frame synchronization to send uplink channel samples and received downlink channel samples as in normal mode while transmitting status information data on the `abe_pdm_frame` line.

---

#### **23.6.2.4.3.4 Multiple Status Information Data Access**

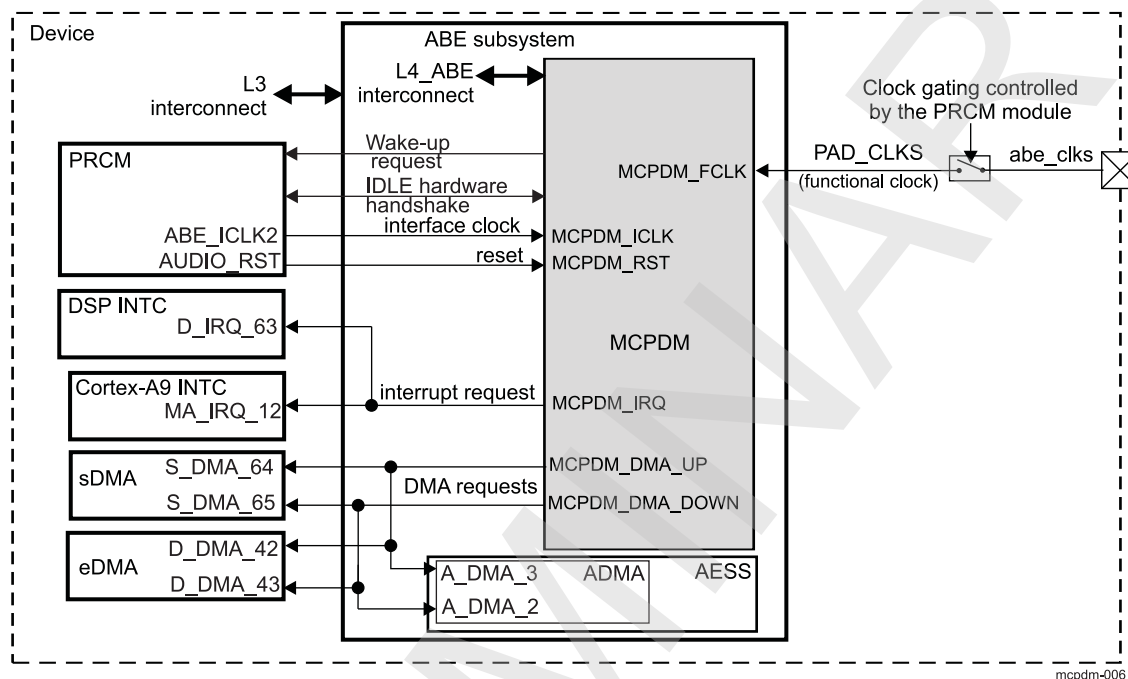

Multiple status information data can be sent by the external audio companion chip to the McPDM module every four frames.

### 23.6.3 McPDM Integration

This section describes the McPDM module integration in the device, including information about clocks, resets, and hardware requests.

Figure 23-165 shows the McPDM integration.

**Figure 23-165. McPDM Integration**

**NOTE:** For more information about the idle hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 23-456 through Table 23-458 summarize the integration of the module in the device.

**Table 23-456. Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
MCPDM	PD_AUDIO	YES	L4_ABE

**Table 23-457. Clocks and Resets**

	MCPDM_DMA_DOWN	A_DMA_2	ADMA	McPDM downlink path DMA request to the ADMA

**NOTE:**

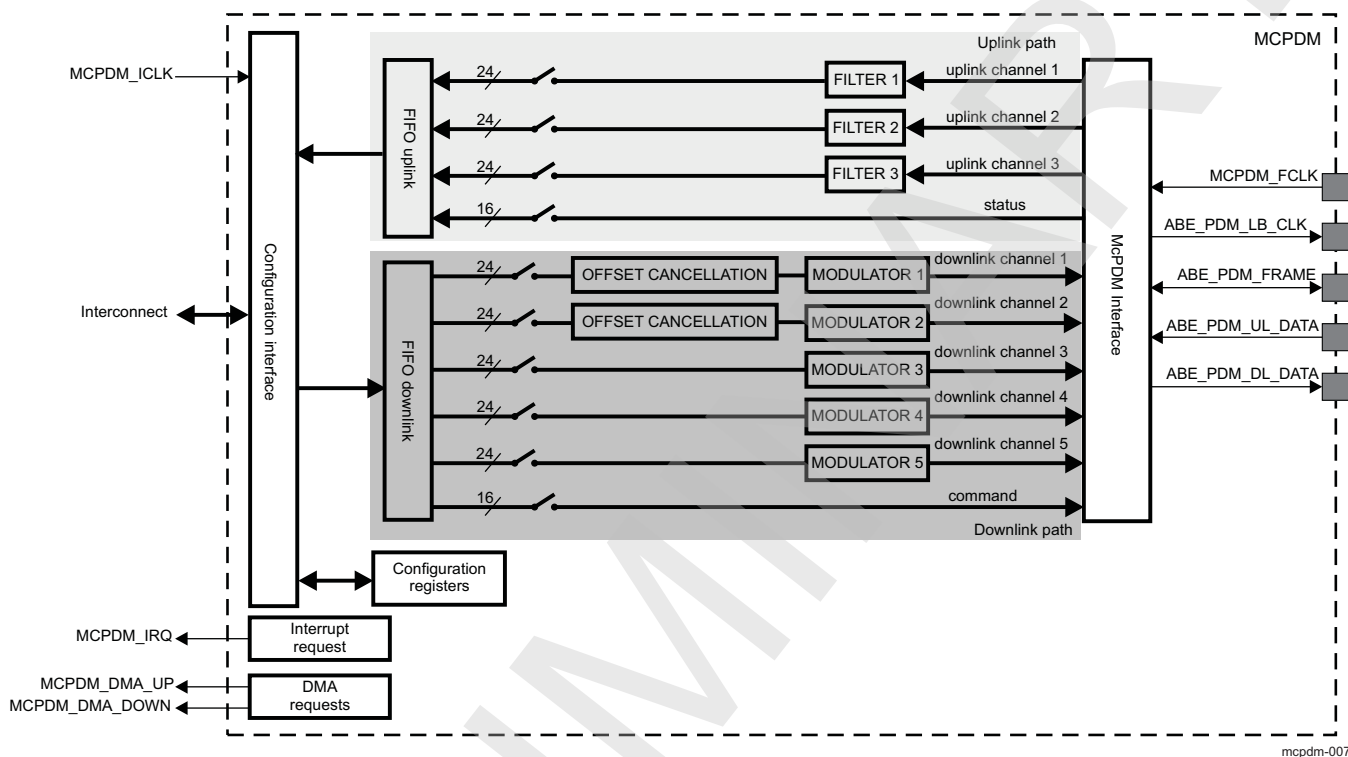

- For the description of the interrupt source, see [Section 23.6.4.5, Interrupt Requests](#).
- For the description of the DMA source, see [Section 23.6.4.6, DMA Requests](#).

## 23.6.4 McPDM Functional Description

### 23.6.4.1 McPDM Block Diagram

Figure 23-166 shows the McPDM block diagram.

Figure 23-166. McPDM Block Diagram

### 23.6.4.2 McPDM Clock Configuration

The functional clock MCPDM\_FCLK is provided by the external audio companion chip. Its frequency can be either 17.64 MHz for a sampling frequency of 88.2/176.4 kHz, or 19.2 MHz for a sampling frequency of 96/192 kHz.

The functional clock is also looped-back to the audio companion chip through ABE\_PDM\_LB\_CLK for resynchronization purposes.

### 23.6.4.3 McPDM Software Reset

To perform a software reset of the McPDM module, the MCPDM\_SYSCONFIG[0] SOFTRESET bit must be set to 1. Reading the MCPDM\_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: The software reset is ongoing.
- Read 0: The software reset is complete.

Software must ensure that the software reset completes before doing McPDM operations. Moreover, uplink and downlink paths can be independently software reset by setting the MCPDM\_CTRL[11] SW\_UP\_RST bit for the uplink path, and the MCPDM\_CTRL[12] SW\_DN\_RST bit for the downlink path to 1. The software reset is stopped by clearing the MCPDM\_CTRL[11] SW\_UP\_RST bit for the uplink path, and the MCPDM\_CTRL[12] SW\_DN\_RST bit for the downlink path to 0.

The software reset of the McPDM module, after completion, put all McPDM registers in their default state. The downlink/uplink reset, resets only the downlink/uplink hardware logic (no registers are affected).

### 23.6.4.4 McPDM Power Management

Table 23-459 describes the power-management features available to the McPDM module.

**Table 23-459. Local Power-Management Features**

Feature	Registers	Description
Clock autogating	N/A	Feature not available
Slave idle modes	MCPDM_SYSCONFIG[3:2] IDLEMODE bit field	Force-idle, no-idle, smart-idle, and smart-idle wake-up capable modes are available for the interface clock
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	MCPDM_IRQWAKEEN and MCPDM_DMAWAKEEN registers	Each register holds one active-high enable bit per event source able to generate wake-up signal
Audio channel enable	MCPDM_CTRL[0] PDM_UP1_EN to MCPDM_CTRL[2] PDM_UP3_EN bits for audio uplink channels MCPDM_CTRL[3] PDM_DN1_EN to MCPDM_CTRL[7] PDM_DN5_EN bits for audio downlink channels	Each of these bits allows enabling (setting to 1) or disabling (clearing to 0) the corresponding audio channel
Status channel enable	MCPDM_CTRL[10] STATUS_INT bit for the status channel	This bit allows enabling (set to 1) or disabling (clear to 0) the status channel
Command channel enable	MCPDM_CTRL[9] CMD_INT bit for the command channel	This bit allows enabling (set to 1) or disabling (clear to 0) the command channel

The MCPDM\_ICLK interface clock is controlled through the power, reset, and clock management (PRCM) module by using idle request and acknowledge signals. The MCPDM\_SYSCONFIG[3:2] IDLEMODE bit field allows controlling the interface clock gating in idle mode.

For the uplink path, the interface clock can be put in idle after uplink path has been enabled. Wakeup is available according to the MCPDM\_IRQWAKEEN and MCPDM\_DMAWAKEEN register settings and the FIFO uplink threshold configured in the MCPDM\_FIFO\_CTRL\_UP[3:0] UP\_TRESH bit field. The wake-up signal is asserted when the FIFO uplink level is equal to, or greater than the FIFO uplink threshold value.

For the downlink path, the interface clock can be put in idle after the FIFO downlink level has reached at least once the FIFO downlink threshold. Wakeup is available according to the MCPDM\_IRQWAKEEN and MCPDM\_DMAWAKEEN register settings and the FIFO downlink threshold configured in the MCPDM\_FIFO\_CTRL\_DN[3:0] DN\_TRESH bit field. The wake-up signal is asserted when the FIFO downlink level is below the FIFO downlink threshold value.

### 23.6.4.5 McPDM Interrupt Requests

The McPDM can generate interrupt requests to the Cortex-A9 MPU and DSP interrupt controllers through the MCPDM\_IRQ signal.

Table 23-460 lists the nonmaskable and maskable event flags and their mask that can cause the McPDM module to generate interrupts.

Table 23-460. Interrupt Events

Nonmaskable Event Flag <sup>(1)</sup>	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MCPDM_IRQSTATUS_RAW[11] UP_IRQ_FULL	MCPDM_IRQSTATUS[11] UP_IRQ_FULL	MCPDM_IRQENABLE_CLR[11] UP_IRQ_FULL_MASK	MCPDM_IRQENABLE_SET[11] UP_IRQ_FULL_MASK	FIFO-uplink-full event. This event occurs when FIFO uplink is already full and a new word is written to the FIFO uplink by the uplink part of the McPDM module.
MCPDM_IRQSTATUS_RAW[10] UP_IRQ_ALST_FULL	MCPDM_IRQSTATUS[10] UP_IRQ_ALST_FULL	MCPDM_IRQENABLE_CLR[10] UP_IRQ_ALST_FULL_MASK	MCPDM_IRQENABLE_SET[10] UP_IRQ_ALST_FULL_MASK	FIFO-uplink-almost-full event. This event occurs when FIFO uplink contains (FIFO uplink size - 1) words and a new word is written to the FIFO uplink by the uplink part of the McPDM module.
MCPDM_IRQSTATUS_RAW[9] UP_IRQ_EMPTY	MCPDM_IRQSTATUS[9] UP_IRQ_EMPTY	MCPDM_IRQENABLE_CLR[9] UP_IRQ_EMPTY_MASK	MCPDM_IRQENABLE_SET[9] UP_IRQ_EMPTY_MASK	FIFO-uplink-empty event. This event occurs when FIFO uplink is already empty and a new word is read from the FIFO uplink by the software.
MCPDM_IRQSTATUS_RAW[8] UP_IRQ	MCPDM_IRQSTATUS[8] UP_IRQ	MCPDM_IRQENABLE_CLR[8] UP_IRQ_MASK	MCPDM_IRQENABLE_SET[8] UP_IRQ_MASK	FIFO-uplink-read-request event. This event occurs when the number of words stored in the FIFO uplink is equal to or greater than the FIFO uplink threshold.
MCPDM_IRQSTATUS_RAW[3] DN_IRQ_FULL	MCPDM_IRQSTATUS[3] DN_IRQ_FULL	MCPDM_IRQENABLE_CLR[3] DN_IRQ_FULL_MASK	MCPDM_IRQENABLE_SET[3] DN_IRQ_FULL_MASK	FIFO-downlink-full event. This event occurs when FIFO downlink is already full and a new word is written to the FIFO downlink by the software.
MCPDM_IRQSTATUS_RAW[2] DN_IRQ_ALST_EMPTY	MCPDM_IRQSTATUS[2] DN_IRQ_ALST_EMPTY	MCPDM_IRQENABLE_CLR[2] DN_IRQ_ALST_EMPTY_MASK	MCPDM_IRQENABLE_SET[2] DN_IRQ_ALST_EMPTY_MASK	FIFO-downlink-almost-empty event. This event occurs when FIFO downlink contains one word and a new word is read from the FIFO downlink by the downlink part of the McPDM module.
MCPDM_IRQSTATUS_RAW[1] DN_IRQ_EMPTY	MCPDM_IRQSTATUS[1] DN_IRQ_EMPTY	MCPDM_IRQENABLE_CLR[1] DN_IRQ_EMPTY_MASK	MCPDM_IRQENABLE_SET[1] DN_IRQ_EMPTY_MASK	FIFO-downlink-empty event. This event occurs when FIFO downlink is empty and a new word is read from the FIFO downlink by the downlink part of the McPDM module.
MCPDM_IRQSTATUS_RAW[0] DN_IRQ	MCPDM_IRQSTATUS[0] DN_IRQ	MCPDM_IRQENABLE_CLR[0] DN_IRQ_MASK	MCPDM_IRQENABLE_SET[0] DN_IRQ_MASK	FIFO-downlink-write-request event. This event occurs when the number of words stored in the FIFO downlink is less than the FIFO downlink threshold.

<sup>(1)</sup> The MCPDM\_IRQSTATUS\_RAW register is mainly used for debug purposes.

### CAUTION

Once an event generating the interrupt request has been processed by the software, this event must be cleared by writing a logical 1 to the corresponding bit of the **MCPDM\_IRQSTATUS** register.

Writing a logical 1 in a bit of the **MCPDM\_IRQSTATUS** register also clears the corresponding bit in the **MCPDM\_IRQSTATUS\_RAW** register to 0.

An event can generate an interrupt request when a logical 1 is written to the corresponding mask bit in the **MCPDM\_IRQENABLE\_SET** register. Events are reported in the **MCPDM\_IRQSTATUS** and **MCPDM\_IRQSTATUS\_RAW** registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the `MCPDM_IRQENABLE_CLR` register. Events are only reported in the `MCPDM_IRQSTATUS_RAW` register.

In case of the `MCPDM_IRQSTATUS_RAW` register, the event is reported in the corresponding bit, even if the interrupt request generation is disabled for this event.

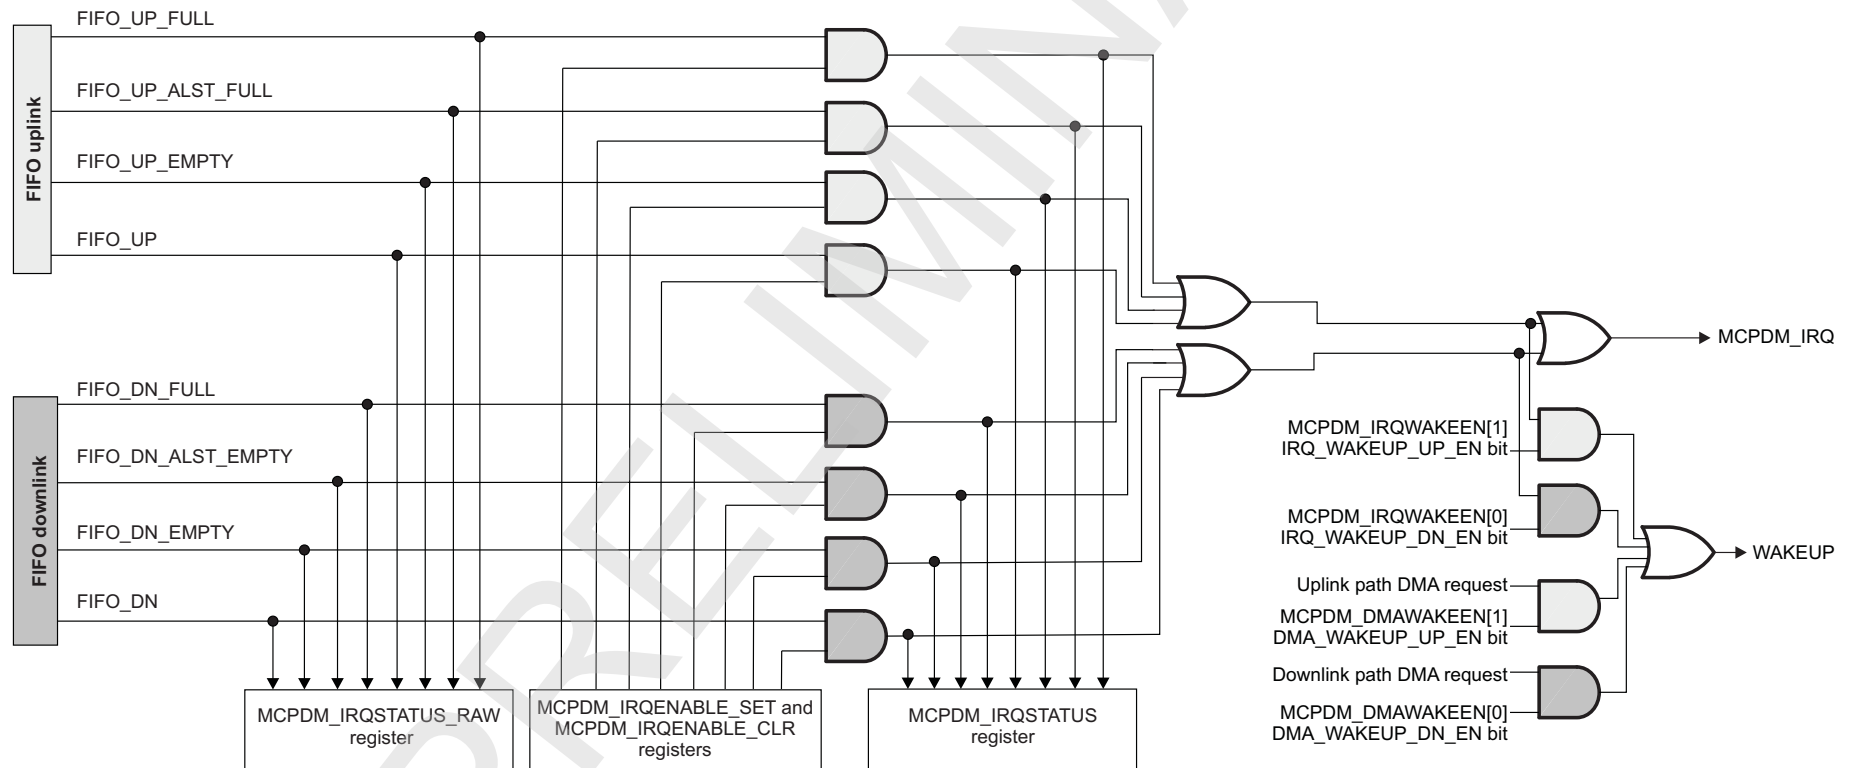

Writing a logical 1 in a bit of the `MCPDM_IRQSTATUS_RAW` register sets the corresponding bit in the `MCPDM_IRQSTATUS` register to 1.

The `MCPDM_IRQSTATUS_RAW` register is mostly used for debug purposes.

For more information about interrupt request signal mapping, see [Table 23-458](#).

[Figure 23-167](#) shows the interrupt tree of the McPDM module.

**Figure 23-167. Interrupt Tree**

mcpdm-008

### 23.6.4.6 McPDM DMA Requests

The McPDM module can generate two DMA requests to the system DMA (sDMA), audio DMA (ADMA), and DSP DMA (eDMA) controllers:

- The uplink path can generate a DMA request through the MCPDM\_DMA\_UP signal.
- The downlink path can generate a DMA request through the MCPDM\_DMA\_DOWN signal.

[Table 23-461](#) lists the DMA requests of the McPDM module.

**Table 23-461. McPDM DMA Requests**

DMA Request Signal	DMA Request Generation Enabling Bit	DMA Request Generation Disabling Bit	Description
MCPDM_DMA_UP	<a href="#">MCPDM_DMAENABLE_SET</a> [1] DMA_UP_ENABLE	<a href="#">MCPDM_DMAENABLE_CLR</a> [1] DMA_UP_ENABLE	Uplink path DMA request. This request is generated when the number of words in the FIFO uplink is equal to, or above the FIFO uplink threshold.
MCPDM_DMA_DOWN	<a href="#">MCPDM_DMAENABLE_SET</a> [0] DMA_DN_ENABLE	<a href="#">MCPDM_DMAENABLE_CLR</a> [0] DMA_DN_ENABLE	Downlink path DMA request. This request is generated when the number of words in the FIFO downlink is below the FIFO downlink threshold.

To enable or disable the DMA request generation on the MCPDM\_DMA\_UP signal, one of the following actions must be performed:

- Write a logical 1 to the [MCPDM\\_DMAENABLE\\_SET](#)[1] DMA\_UP\_ENABLE bit to enable the DMA request generation on the MCPDM\_DMA\_UP signal.
- Write a logical 1 to the [MCPDM\\_DMAENABLE\\_CLR](#)[1] DMA\_UP\_ENABLE bit to disable the DMA request generation on the MCPDM\_DMA\_UP signal.

To enable or disable the DMA request generation on the MCPDM\_DMA\_DOWN signal, one of the following actions must be performed:

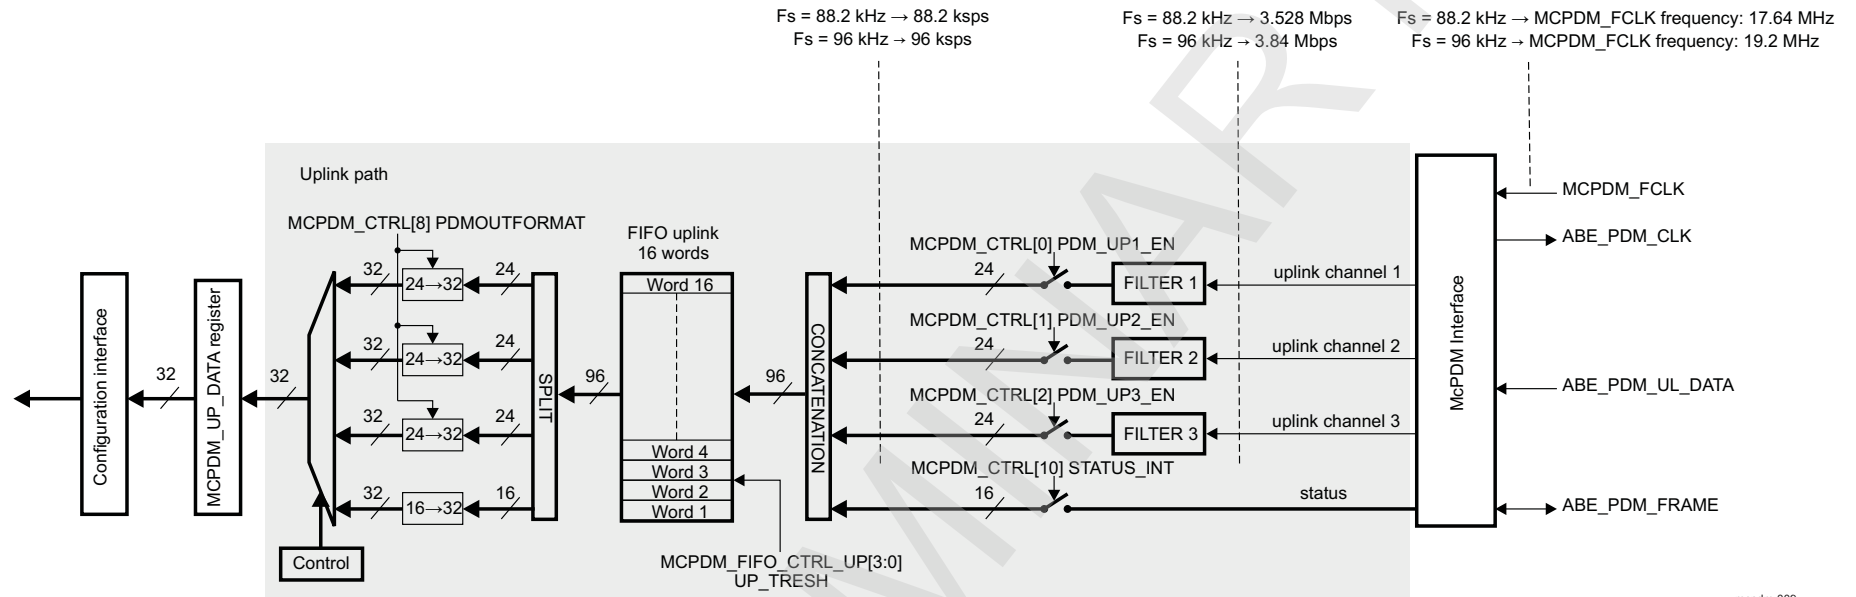

- Write a logical 1 to the [MCPDM\\_DMAENABLE\\_SET](#)[0] DMA\_DN\_ENABLE bit to enable the DMA request generation on the MCPDM\_DMA\_DOWN signal.
- Write a logical 1 to the [MCPDM\\_DMAENABLE\\_CLR](#)[0] DMA\_DN\_ENABLE bit to disable the DMA request generation on the MCPDM\_DMA\_DOWN signal.

For more information about DMA request signals mapping, see [Table 23-458](#).

### 23.6.4.7 Uplink Path

[Figure 23-168](#) is a detailed block diagram of the uplink path in the McPDM module.

Figure 23-168. Uplink Path Detailed Block Diagram

mcpdm-009

### 23.6.4.7.1 Uplink Path Features

The uplink path has the following features:

- Three audio uplink channels
- One status channel
- Decimation filter for each audio uplink channel
- 16-word FIFO uplink with threshold setting
- Audio channel data formatting
- High-frequency sampling feature

### 23.6.4.7.2 Uplink Path Description

#### 23.6.4.7.2.1 Uplink Data Received From the External Audio Companion Chip

The McPDM interface receives audio uplink channel data and status information data from the external audio companion chip at a clock rate of 17.64 MHz for a sampling frequency of 88.2 kHz, or 19.2 MHz for a sampling frequency of 96 kHz. This is the low-frequency sampling feature which is enabled by default. The uplink path support high-frequency sampling feature to work with an ultrasonic external microphone. This feature is enabled by setting the `MCPDM_CTRL[13] DIV_SEL` bit to 1. Thus, the McPDM interface receives audio uplink channel data and status information data from the external audio companion chip at a clock rate of 17.64 MHz for a sampling frequency of 176,4 kHz, or 19.2 MHz for a sampling frequency of 192 kHz.

The McPDM interface extracts each data bit related to audio and sends it to the decimation filter of the corresponding channel. So, for each audio uplink channel, the McPDM interface generates one bit data flow to the corresponding decimation filter at a rate of 3.528 Mbps for a sampling frequency of 88.2 kHz, or 3.84 Mbps for a sampling frequency of 96 kHz.

Moreover, when status information data are detected on the frame synchronization signal (`ABE_PDM_FRAME`), the status information are recovered and sent to the status channel. When no status information data is detected on the frame synchronization signal, a null word (0x0000) is sent on the status channel.

See [Section 23.6.2.4.1, Protocols and Data Formats in Normal Mode](#), for more information about protocols and data formats in normal mode, and [Section 23.6.2.4.3, Protocols and Data Formats in Status Mode](#), for more information about protocols and data formats in status mode.

#### 23.6.4.7.2.2 Decimation Filter

Each bit data flow related to an audio uplink channel and provided by the McPDM interface is processed by a decimation filter. The aim of this filter is to band-limit the noise and to downsample the incoming bit data flow to generate a 24-bit wide signed data flow at a rate of 88.2 kbps for a sampling frequency of 88.2 kHz, or 96 kbps for a sampling frequency of 96 kHz.

#### 23.6.4.7.2.3 FIFO Uplink Management

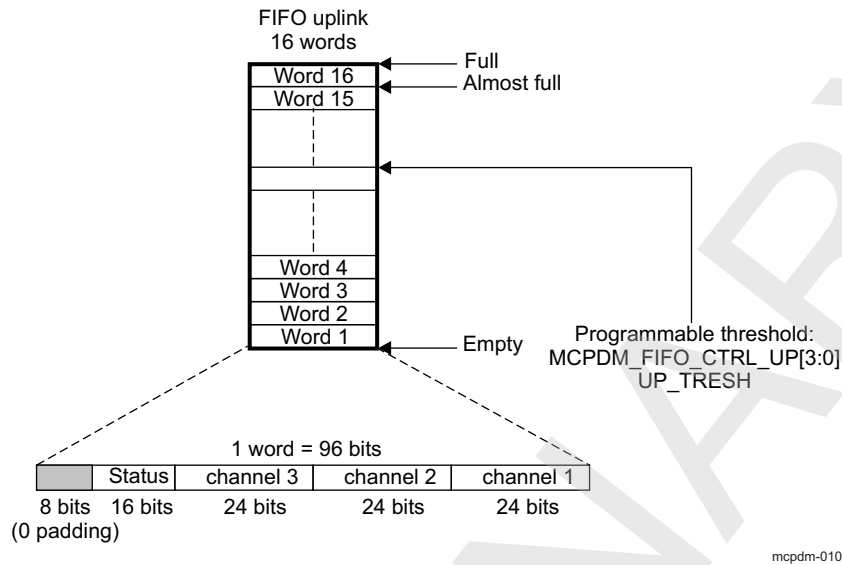

##### 23.6.4.7.2.3.1 General Description

The McPDM module implements a FIFO for the uplink path for communication with the host processor in the device. The FIFO uplink can store up to 16 words. Each word is 96 bits wide and is a combination of 24-bit wide signed audio uplink channel data coming from decimation filters and 16-bit wide status information data coming from the McPDM interface.

[Figure 23-169](#) shows the FIFO uplink overview.

Figure 23-169. FIFO Uplink Overview

23.6.4.7.2.3.2 FIFO Operations

The FIFO uplink is filled with audio uplink channel data coming from decimation filters and status information data from the McPDM interface. Once the FIFO uplink threshold (`MCPDM_FIFO_CTRL_UP[3:0] UP_TRESH` bit field) is reached and depending on conditions, an event occurs and generates an interrupt or DMA request.

**NOTE:** See Section 23.6.4.5, *McPDM Interrupt Requests*, for more information about events generating an interrupt request, and Section 23.6.4.6, *McPDM DMA Requests*, for more information about conditions for DMA request generation.

When an interrupt request upon a FIFO-uplink-read-request event or a `MCPDM_DMA_UP` request occurs, the host processor or the DMA controller must read the words from the FIFO uplink (`MCPDM_UP_DATA` register). The number of read accesses from the host/DMA is determined by the following equation:

$$\text{Num\_read\_access} = (\text{PDM\_UP1\_EN} + \text{PDM\_UP2\_EN} + \text{PDM\_UP3\_EN} + \text{STAT\_INT}) * (\text{UP\_THRESH})$$
 where the `PDM_UP_THRESHOLD` is programmed through the `MCPDM_FIFO_CTRL_UP[3:0] UP_TRESH` bit field. `PDM_UP1_EN`, `PDM_UP2_EN`, `PDM_UP3_EN`, and `STAT_INT` are boolean values representing whether the corresponding channel is enable or not.

For example, if audio uplink channels 1 and 3 are enabled, audio uplink channel 2 is disabled, and status channel is enabled, and the uplink threshold is programmed for one line only (`MCPDM_FIFO_CTRL_UP[3:0] UP_TRESH = 0x0`):

- `Num_read_access = 3` because two audio uplink and the status channels are enabled.
- The first reading of the `McPDM_UP_DATA` register should correspond to the audio uplink channel 1 data.
- The second reading of the `McPDM_UP_DATA` register should correspond to the audio uplink channel 3 data.
- The third reading of the `McPDM_UP_DATA` register should correspond to the status information data.

---

**NOTE:** No status information has been sent by the external audio companion chip if the status channel is enabled and the 16 lower bits of the corresponding data read from the `MCPDM_UP_DATA` register is 0x0000 .

The audio uplink and status channels cannot be enabled/disabled on the fly during uplink signaling. The uplink path must first be forced to reset by setting the `MCPDM_CTRL[11]` `SW_UP_RST` bit to 1 before enabling or disabling any channels.

---

Because the audio uplink channel data are 24 bits wide and the `MCPDM_UP_DATA` register is 32 bits wide, the `MCPDM_CTRL[8]` `PDMOUTFORMAT` bit allows selecting the justification of the 24-bit audio uplink channel data in the `MCPDM_UP_DATA` register:

- When the `MCPDM_CTRL[8]` `PDMOUTFORMAT` bit is cleared to 0, the 24-bit wide signed audio uplink channel data are left-justified with eight 0 padding bits for the lower bits.
  - When the `MCPDM_CTRL[8]` `PDMOUTFORMAT` is set to 1, the 24-bit wide signed audio uplink channel data are right-justified and sign-extended.
- 

**NOTE:** The `MCPDM_CTRL[8]` `PDMOUTFORMAT` bit does not affect the status information format. When the status information data are read from the `MCPDM_UP_DATA` register, only the 16 lower bits are significant.

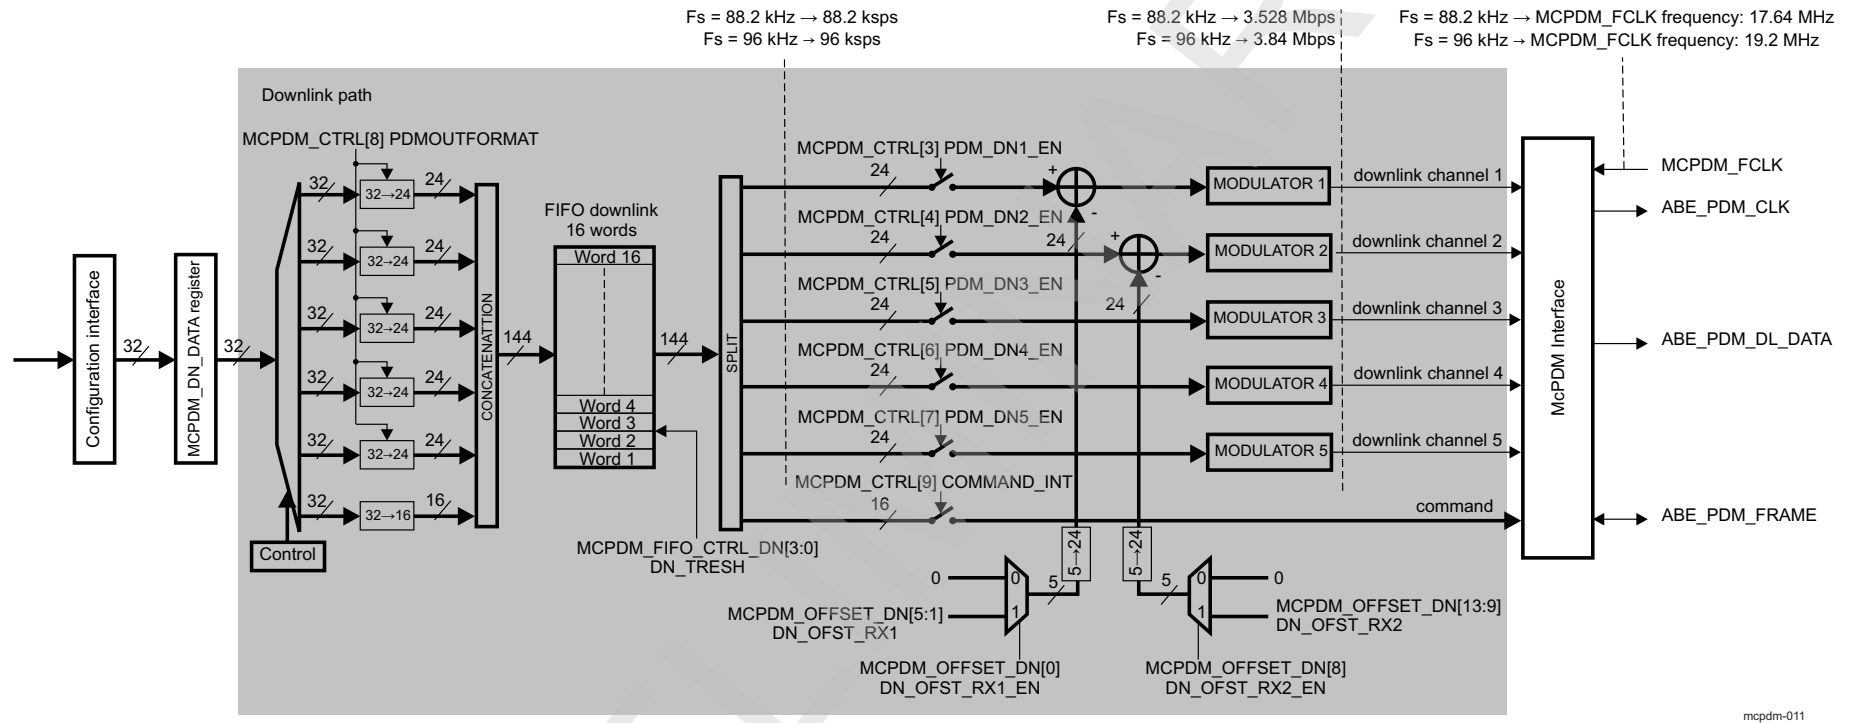

The setting of the `MCPDM_CTRL[8]` `PDMOUTPUTFORMAT` bit also affects the audio downlink channel data format.

---

23.6.4.8 Downlink Path

Figure 23-170 is a detailed block diagram of the downlink path in the McPDM module.

Figure 23-170. Downlink Path Detailed Block Diagram

mcpdm-011

### 23.6.4.8.1 Downlink Path Features

The downlink path has the following features:

- Five audio downlink channels
- Offset cancellation for audio downlink channels 1 and 2
- One command channel
- Delta-sigma modulator for each audio downlink channel
- 16-word FIFO downlink with threshold setting
- Audio channel data formatting

### 23.6.4.8.2 Downlink Path Description

#### 23.6.4.8.2.1 FIFO Downlink Management

##### 23.6.4.8.2.1.1 General Description

The McPDM module implements a FIFO for the downlink path for communication with the host processor in the device. The FIFO downlink can store up to 16 words. Each word is 144 bits wide and is a combination of 24-bit wide signed audio downlink channels data and 16-bit wide command information data.

Figure 23-171 shows the FIFO downlink overview.

**Figure 23-171. FIFO Downlink Overview**

mcpdm-012

##### 23.6.4.8.2.1.2 FIFO Operations

The FIFO downlink is read by the McPDM module and data related to the audio downlink channels are sent to the delta-sigma modulators, while the data related to the command information is sent to the McPDM interface. Once the FIFO pointer goes below the programmed threshold (`MCPDM_FIFO_CTRL_DN[3:0] DN_TRESH`), a DMA or interrupt request is sent to the DMA or interrupt handler and, depending on conditions, an event occurs and generates an interrupt or DMA request.

**NOTE:** See [Section 23.6.4.5, McPDM Interrupt Requests](#), for more information about events generating an interrupt request, and [Section 23.6.4.6, McPDM DMA Requests](#), for more information about conditions for DMA request generation.

When an interrupt request upon a FIFO downlink write-request event or a MCPDM\_DMA\_DOWN request occurs, it indicates that the next words are available to be written to the [MCPDM\\_DN\\_DATA](#) register. The minimum number of write accesses from the host/DMA is determined by the following equation:

$$\text{Num\_min\_write\_access} = \text{PDM\_DN1\_EN} + \text{PDM\_DN2\_EN} + \text{PDM\_DN3\_EN} + \text{PDM\_DN4\_EN} + \text{PDM\_DN5\_EN} + \text{CMD\_INT}$$

PDM\_DN1\_EN, PDM\_DN2\_EN, PDM\_DN3\_EN, PDM\_DN4\_EN, PDM\_DN5\_EN and CMD\_INT are boolean values representing whether the corresponding channel is enable or not.

The maximum number of write accesses (before overwriting the data in the FIFO still to be transmitted) from the host/DMA is determined by the following equation:

$$\text{Num\_max\_write\_access} = (\text{FIFO\_SIZE} - \text{DN\_THRESH} + 1) * (\text{PDM\_DN1\_EN} + \text{PDM\_DN2\_EN} + \text{PDM\_DN3\_EN} + \text{PDM\_DN4\_EN} + \text{PDM\_DN5\_EN} + \text{CMD\_INT})$$

FIFO\_SIZE is the size of the downlink FIFO and DN\_THRESH is the downlink FIFO threshold, programmed through the [MCPDM\\_FIFO\\_CTRL\\_DN\[3:0\]](#) DN\_THRESHOLD bit field.

For example, if audio downlink channels 1, 2, and 3 are enabled, audio downlink channels 4 and 5 are disabled, and the command channel is enabled:

- Num\_min\_write\_access = 4, because three audio downlinks and the command channels are enabled.
- The first writing to the McPDM\_DN\_DATA register should correspond to the audio downlink channel 1 data.
- The second writing to the McPDM\_DN\_DATA register should correspond to the audio downlink channel 2 data.
- The third writing to the McPDM\_DN\_DATA register should correspond to the audio downlink channel 3 data.
- The fourth writing to the McPDM\_DN\_DATA register should correspond to the command information data.

---

**NOTE:** When the command channel is enabled and no command data needs to be sent to the external audio companion chip, 0x0000 must be written to the 16 lower bits of the [MCPDM\\_DN\\_DATA](#) register as command data.

The audio downlink and command channels cannot be enabled/disabled on the fly during downlink signaling. The downlink path must first be forced to reset by setting the [MCPDM\\_CTRL\[12\]](#) SW\_DN\_RST bit to 1 before enabling or disabling any channels.

---

Because the audio downlink channel data are 24 bits wide and the [MCPDM\\_DN\\_DATA](#) register is 32 bits wide, the [MCPDM\\_CTRL\[8\]](#) PDMOUTFORMAT bit indicates the justification of the 24-bit audio downlink channel data in the [MCPDM\\_DN\\_DATA](#) register:

- When the [MCPDM\\_CTRL\[8\]](#) PDMOUTFORMAT is cleared to 0, the 24-bit wide signed audio downlink channel data are left-justified with eight 0 padding bits for the lower bits.
- When [MCPDM\\_CTRL\[8\]](#) PDMOUT FORMAT is set to 1, the 24-bit wide signed audio downlink channel data are right-justified and sign-extended.

---

**NOTE:** The [MCPDM\\_CTRL\[8\]](#) PDMOUTFORMAT bit does not affect the command information format. When the command information data are written to the [MCPDM\\_DN\\_DATA](#) register, only the 16 lower bits are significant.

The setting of the [MCPDM\\_CTRL\[8\]](#) PDMOUTPUTFORMAT bit also affects the audio uplink channel data format.

---

### 23.6.4.8.2.1.3 Offset Cancellation

Because audio downlink channels 1 and 2 are related to the analog headset downlink path within the external audio companion chip, an offset cancellation feature is available for these channels to eliminate the offset of the analog headset downlink path.

When the offset cancellation feature is enabled, an offset value is subtracted from the audio data before being sent to the pulse-density modulator. The offset values are read from registers within the external audio companion chip and configured in the `MCPDM_DN_OFFSET[5:1]` `DN_OFST_RX1` bit field for the audio downlink channel 1, and in the `MCPDM_DN_OFFSET[13:9]` `DN_OFST_RX2` bit field for the audio downlink channel 2.

The offset cancellation feature is enabled or disabled by configuring the `MCPDM_DN_OFFSET[0]` `DN_OFST_RX1_EN` bit for the audio downlink channel 1, and the `MCPDM_DN_OFFSET[8]` `DN_OFST_RX2_EN` bit for the audio downlink channel 2 (00: Disabled, 10: Enabled).

#### 23.6.4.8.2.1.4 Pulse-Density Modulators

Each 24-bit wide data related to an audio downlink channel is processed by a pulse-density modulator. The aim of this modulator is to upsample the incoming audio data and then perform a 1-bit pulse-density modulation to generate a 1-bit data flow at a rate of 3.528 Mbps for a sampling frequency of 88.2 kHz, or 3.84 Mbps for a sampling frequency of 96 kHz. The 1-bit pulse-density modulation allows using a 1-bit analog-to-digital converter implemented in the external audio companion chip to convert the audio digital data into an audio analog signal.

##### 23.6.4.8.2.1.4.1 Pulse-Density Modulators watchdog logic

If the 1-bit data flow coming out of the pulse-density modulator has twelve or more consecutive 1s or 0s, the pulse-density modulator had entered into unstable or saturated condition. Unstable or saturated condition leads to unpredictable behavior of the pulse-density modulator, thereby producing random noise. To prevent this unstable or saturated condition from occurring, a watchdog logic is used to monitor the 1-bit output of the pulse-density modulator for twelve consecutive 1s or twelve consecutive 0s. If entry to unstable condition is detected, the watchdog logic asserts the reset of the McPDM downlink paths for one clock pulse to put the McPDM hardware logic, related to the downlink mechanism, to initial state.

The watchdog logic is disabled by default. To enable it, the `MCPDM_CTRL[14]` `WD_EN` bit must be set to 0x1. If the watchdog logic is disabled, only the assertion of the downlink path reset `MCPDM_CTRL[12]` `SW_DN_RST` bit is allowed to reset the McPDM hardware logic, which is related to the downlink mechanism. If the watchdog logic is enabled, the downlink mechanism logic is reset when the downlink path reset or the watchdog reset is asserted.

Figure 23-172 shows the watchdog logic mechanism.

Figure 23-172. McPDM Watchdog Logic

mcpdm-014

#### 23.6.4.8.2.1.5 Downlink Data Sent to the External Audio Companion Chip

The McPDM interface transmits the audio downlink channel data and command data to the external audio companion chip at a clock rate of 17.64 MHz for a sampling frequency of 88.2 kHz, or 19.2 MHz for a sampling frequency of 96 kHz.

The command data are sent on the frame synchronization signal (ABE\_PDM\_FRAME) when the command channel is enabled. When the command channel is disabled or the command data is 0x0000, no command data is sent on the frame synchronization signal.

See [Section 23.6.2.4.1, Protocols and Data Formats in Normal Mode](#), for more information about protocols and data formats in normal mode, and [Section 23.6.2.4.2, Protocols and Data Formats in Command Mode](#), for more information about protocols and data formats in command mode.

#### 23.6.4.9 Error Reporting

During normal operation, when interrupt and DMA requests are properly served, no FIFO-uplink-full and no FIFO-downlink-empty event should occur.

Nevertheless, if one of these events occurs, the corresponding path must be forced to reset by software before being reconfigured. For more information about events servicing, see [Section 23.6.5.1.2, McPDM Events Servicing](#).

Moreover, a FIFO-uplink-empty or FIFO-downlink-full event occurs only in the case where all the channels of the corresponding path have been disabled during normal operation.

**NOTE:** Channels must not be enabled or disabled during normal operation.

Channels can be enabled or disabled when the corresponding path is forced to reset. For more information about McPDM software reset, see [Section 23.6.4.3, McPDM Software Reset](#).

## 23.6.5 McPDM Programming Guide

### 23.6.5.1 McPDM Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

#### 23.6.5.1.1 Global Initialization

##### 23.6.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules in the device when the McPDM module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the environment and the integration of the McPDM. See [Section 23.6.2, McPDM Environment](#), and [Section 23.6.3, McPDM Integration](#), for more information.

[Table 23-462](#) describes the global initialization for surrounding modules.

**Table 23-462. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM module	The McPDM interface clock must be enabled and the functional clock must not be gated.
Control module	The McPDM specific pad muxing must be configured in the device control module.
(Optional) Cortex A9 MPU INTC (or DSP INTC)	The Cortex A9 MPU (or DSP) INTC must be configured to enable the interrupt request generation to the Cortex A9 MPU (or DSP) subsystem when interrupt requests are generated by the McPDM module.
(Optional) sDMA (or eDMA or ADMA)	The sDMA (or eDMA or ADMA) controller must be configured to account for the DMA requests generated by the McPDM module in the case of autonomous data transfers from/to memory.
(Optional) Interconnect	For more information about the interconnect configuration, see <a href="#">Chapter 13, Interconnect</a> .
External audio chip	Initialize the external audio chip according to the specific needs.
I <sup>2</sup> C controller	For more information about the I <sup>2</sup> C initialization, see <a href="#">Section 23.1, Multimaster High-Speed I<sup>2</sup>C Controller</a> .

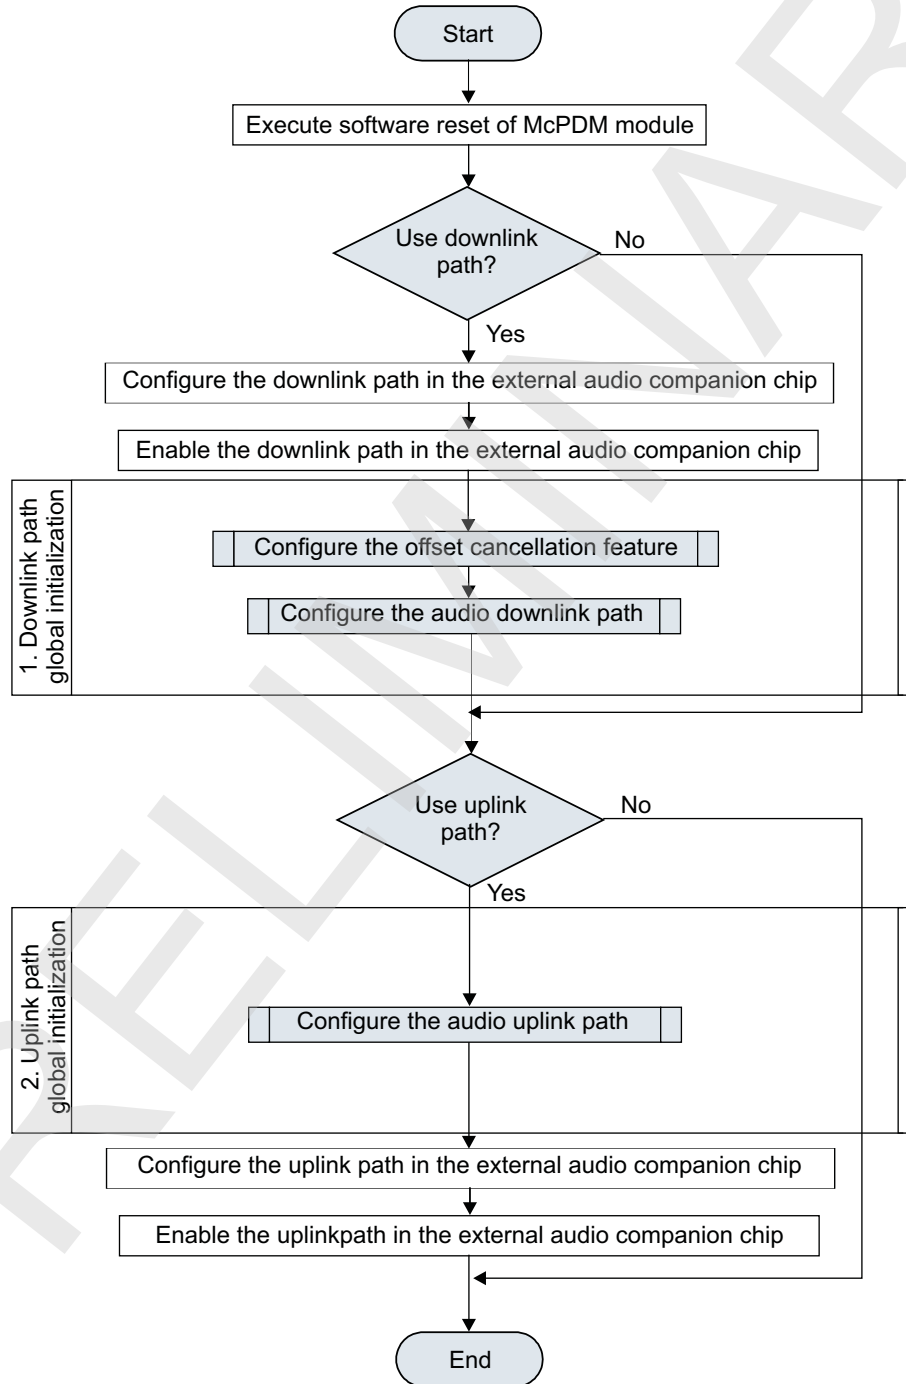

23.6.5.1.1.2 McPDM Global Initialization

23.6.5.1.1.2.1 Main Sequence – McPDM Global Initialization

This procedure initializes the McPDM after a power-on reset (POR) or software reset. Figure 23-173 shows a flow chart for the global initialization of the McPDM module.

Figure 23-173. McPDM Global Initialization Flow Chart

mcpdm-013

The McPDM software reset is executed by writing 0x1 in the `MCPDM_SYSCONFIG[0] SOFTRESET` bit. To detect the reset done event, user software must check this bit until it is cleared to 0x0 by the hardware.

Configuration of the offset cancellation feature is optional. The use of that feature depends on the characteristics of the external audio chip attached to the McPDM interface. If the external chip adds some DC offset on its output, then the offset cancellation feature of the McPDM must be used.

Table 23-463 describes the steps of the downlink path global initialization.

**Table 23-463. McPDM Downlink Path Global Initialization**

Procedure	Step	Access Type	Register/Bit Field/Programming Model	Value
Configure the offset cancellation feature. Only downlink path 1 and downlink path 2 can use the offset cancellation feature.	1. Read the offset value for the audio downlink path 1 from the external audio companion chip via the I <sup>2</sup> C interface.	R	Offset register 1 in the external audio companion chip	OFFSET1
	2. Configure the offset of the audio downlink path 1.	W	MCPDM_DN_OFFSET[5:1] DN_OFST_RX1	OFFSET1
	3. Enable the offset cancellation feature for the audio downlink path 1.	W	MCPDM_DN_OFFSET[0] DN_OFST_RX1_EN	0x1
	4. Read the offset value for the audio downlink path 2 from the external audio companion chip via the I <sup>2</sup> C interface.	R	Offset register 2 in the external audio companion chip	OFFSET2
	5. Configure the offset of the audio downlink path 2.	W	MCPDM_DN_OFFSET[13:9] DN_OFST_RX2	OFFSET2
	6. Enable the offset cancellation feature for the audio downlink path 2.	W	MCPDM_DN_OFFSET[8] DN_OFST_RX2_EN	0x1
Configure the audio downlink path.	1. Enable the interrupt request generation for the downlink path.	W	a. MCPDM_IRQENABLE_SET[3] DN_IRQ_FULL_MASK b. MCPDM_IRQENABLE_SET[2] DN_IRQ_ALMST_EMPTY_MASK c. MCPDM_IRQENABLE_SET[1] DN_IRQ_EMPTY_MASK d. MCPDM_IRQENABLE_SET[0] DN_IRQ_MASK	When downlink DMA request not used: 0xF When downlink DMA request used: 0xE
	2. Configure the FIFO downlink threshold.	W	MCPDM_FIFO_CTRL_DN[3:0] DN_TRESH	FIFO downlink threshold
	3. Enable the DMA request generation for the downlink path (optional: only if DMA request generation for the downlink path is required).	W	MCPDM_DMAENABLE_SET[0] DMA_DN_ENABLE	0x1
	4. Enable the downlink channels.	W	MCPDM_CTRL	See Table 23-459

Table 23-464 describes the steps of the uplink path global initialization.

**Table 23-464. McPDM Uplink Path Global Initialization**

Step	Access Type	Register/Bit Field/Programming Model	Value
1. Enable the interrupt request generation for the uplink path.	W	a. MCPDM_IRQENABLE_SET[11] UP_IRQ_FULL_MASK b. MCPDM_IRQENABLE_SET[10] UP_IRQ_ALMST_FULL_MASK c. MCPDM_IRQENABLE_SET[9] UP_IRQ_EMPTY_MASK d. MCPDM_IRQENABLE_SET[8] UP_IRQ_MASK	When uplink DMA request not used: 0xF When uplink DMA request used: 0xE
2. Configure the FIFO uplink threshold.	W	MCPDM_FIFO_CTRL_UP[3:0] UP_TRESH	FIFO uplink threshold
3. Enable the DMA request generation for the uplink path (optional: only if DMA request generation for the uplink path is required).	W	MCPDM_DMAENABLE_SET[1] DMA_UP_ENABLE	0x1
4. Configure the FIFO uplink sampling frequency.	W	MCPDM_CTRL[13] DIV_SEL	0x-

**Table 23-464. McPDM Uplink Path Global Initialization (continued)**

Step	Access Type	Register/Bit Field/Programming Model	Value
5. Enable the uplink channels.	W	MCPDM_CTRL	See Table 23-459

**23.6.5.1.2 McPDM Events Servicing**

**23.6.5.1.2.1 Downlink Path Event Servicing**

Table 23-465 to Table 23-468 describe the downlink path event servicing.

When the four downlink interrupts are enabled and then the downlink channel(s) is enabled, the FIFO-downlink-write request (MCPDM\_IRQSTATUS = 0x1), instead of the FIFO-downlink-empty request (MCPDM\_IRQSTATUS = 0x2), is generated. The first audio data to be sent is written from the interrupt handler. The McPDM module can work in two ways:

- Enable the desired downlink channels, and then write in the downlink FIFO the audio data that is going to be sent.
- Write the audio data in the downlink FIFO, and then enable the desired downlink channels to send this audio data.

In either way, the FIFO-downlink-write request is generated.

**Table 23-465. FIFO-Downlink-Full Event Servicing**

Step	Access Type	Register/Bit Field/Programming Model	Value
<b>TEST TA: Is FIFO downlink full?</b>	R	MCPDM_IRQSTATUS[3] DN_IRQ_FULL

## 23.7 Digital Microphone Module

This section describes the digital microphone (DMIC) module.

### 23.7.1 DMIC Overview

The digital microphone (DMIC) module consists of an audio module dedicated to a mobile telephone terminal. The DMIC allows the support of up to six digital microphones. It provides an interface between the audio backend (ABE) module and microphones connected through the 6-wire DMIC serial interface.

The DMIC supports six paths. Because each path is composed of two digital microphone channels, the DMIC can be used with three stereo or six mono microphones. Each path is enabled or disabled independently.

The DMIC generates a pulse-density modulated (PDM) stream of bits and transfers it in one period or one half-period of the clock provided by the DMIC (oversampling clock).

Each microphone is directly connected to a filter decimator to extract the audio samples at the desired accuracy and sample rate. Data are stored in the first in first out (FIFO), which is controlled by interrupt request (IRQ) and direct memory access (DMA) request.

The DMIC pads are supplied with 1.8 V. These pads assure the transition to the host supply.

[Figure 23-174](#) shows the DMIC in the device.

Figure 23-174. DMIC

The main features of the DMIC are:

- Six external pin connections (three data lines and three clock lines)
- Using the three clock lines, the DMIC delivers three clock signals (same frequency, individually gateable) for all digital microphones.
- Using the three data lines, the DMIC receives audio data from external microphones.
- Supports stereo (up to three) and mono (up to six) digital microphones
- Each line can support two microphones working in clock phase opposition.
- Selectable functional clock source
- Programmable output clock frequency ( $32 \times FS$ ,  $50 \times FS$ ,  $64 \times FS$ , or  $80 \times FS$ , where  $FS = 48 \text{ kHz}$ )
- Programmable data sampling sensibility (rising or falling edge)
- One RX FIFO (16 words of 144 bits)
- Supports idle request/acknowledge power, reset, and clock management (PRCM) module protocol
- Interconnect sample format: 32 bits (only 24 are significant)
- One IRQ to the microprocessor unit (Cortex™-A9 microprocessor unit [MPU]) and digital signal processor (DSP) subsystems
- One DMA request capability on programmable FIFO threshold

### 23.7.2 DMIC Environment

This section describes the DMIC application fields from an environment point of view (that is, external connections). It presents the DMIC connectivity options, lists possible interfaces, and details the protocol and data format used in each case.

#### 23.7.2.1 DMIC Interface With External MIC

##### 23.7.2.1.1 DMIC Interface Overview

The DMIC interface is a 6-wire interface. The DMIC module can support up to three external stereo and six mono digital microphones. A DMIC is an external module that can deliver data. A clock is sent from the host to the microphone.

Figure 23-175 and Figure 23-176 show two cases of use of the DMIC, but all configurations are possible with stereo and mono digital microphones. The output of the DMIC is in 32-bit format.

Figure 23-175 shows the DMIC used with three stereo DMICs.

Figure 23-175. DMIC With Three Stereo DMICs

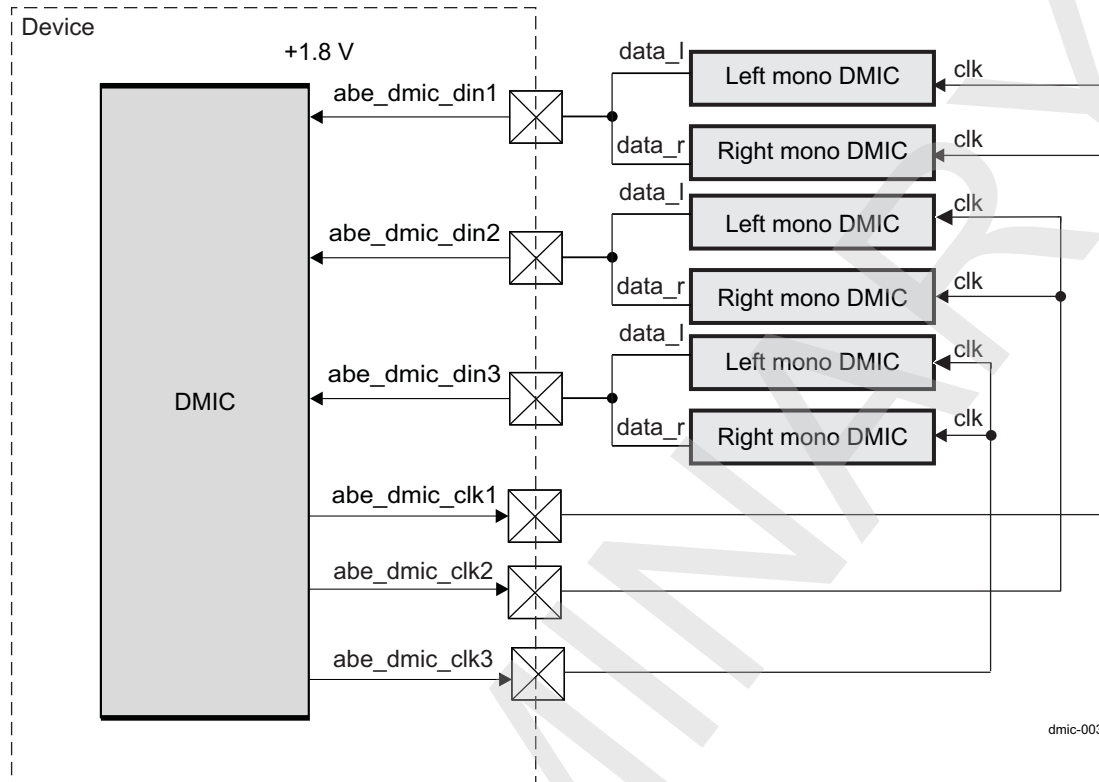

Figure 23-176 shows the DMIC used with six mono DMICs.

Figure 23-176. DMIC With Six Mono DMICs

### 23.7.2.1.2 DMIC Signals

Table 23-507 describes the signals in the DMIC module.

Table 23-507. Input/Output

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value <sup>(1)</sup>
abe_dmic_clk1	O	Digital (stereo) microphone clock output 1	0
abe_dmic_clk2	O	Digital (stereo) microphone clock output 2	0
abe_dmic_clk3	O	Digital (stereo) microphone clock output 3	0
abe_dmic_din1	I	Digital (stereo) microphone data input 1	Hi-Z
abe_dmic_din2	I	Digital (stereo) microphone data input 2	Hi-Z
abe_dmic_din3	I	Digital (stereo) microphone data input 3	Hi-Z

<sup>(1)</sup> I = Input; O = Output; Hi-Z = High impedance

All DMIC external connections have pullup or pulldown resistors, selected and configured in the control module registers.

### 23.7.2.1.3 Serial Data Format

The DMIC generates a PDM stream of bits and transfers it in one period or one half-period of the clock. Then, the filter decimator extracts the 24-bit audio samples.

#### 23.7.2.1.3.1 DMIC Clock Generation and Synchronization

When DMIC\_POLAR is set to 0, the microphone left data is generated on the abe\_dmic\_clk low level. When DMIC\_POLAR is set to 1, the microphone left data is generated on the abe\_dmic\_clk high level. There are three DMIC\_POLARx bits (where x = 1, 2, or 3) corresponding to the three stereo paths:

- [DMIC\\_CTRL\[4\]](#) for path 1

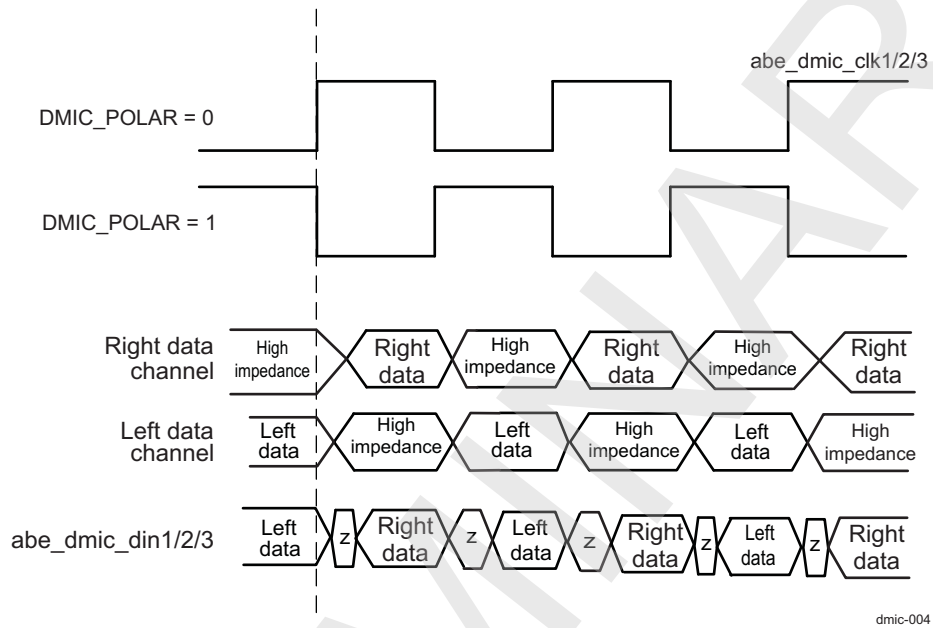

- [DMIC\\_CTRL\[5\]](#) for path 2
- [DMIC\\_CTRL\[6\]](#) for path 3

The DMIC\_POLARx bits are set depending on the configuration of the external digital microphone.

[Figure 23-177](#) is a diagram of the DMIC interface with a DMIC.

**Figure 23-177. DMIC Interface Diagram With External DMICs**

### 23.7.2.2 DMIC Functional Path

The DMIC path processes, decimates, and filters the data from the DMIC interface, and stores the processed data in the FIFO. The FIFO is controlled by IRQ and DMA requests and is fed outside of the DMIC.

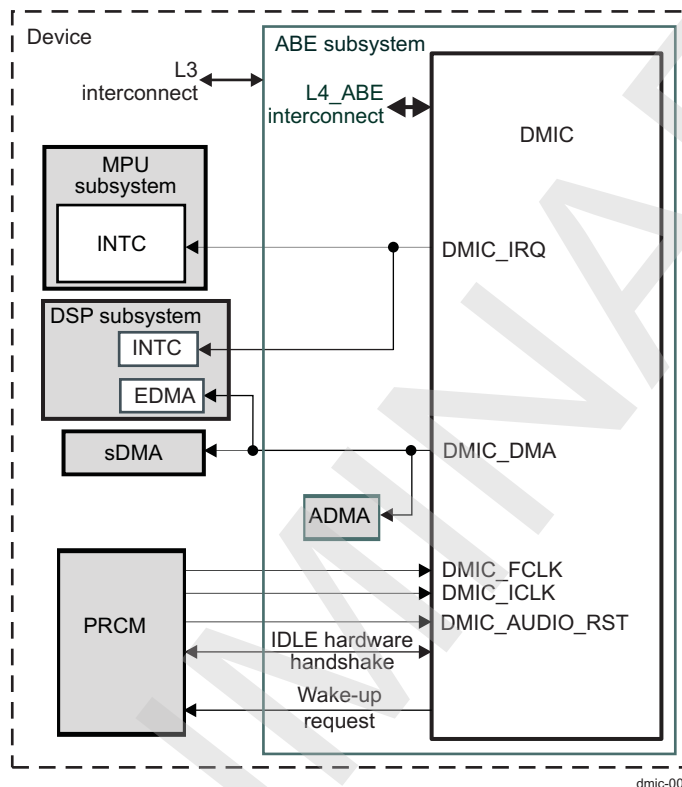

For more information about microphone data processing, see [Section 23.7.4.7, Audio Data Processing](#).

### 23.7.3 DMIC Integration

This section describes the integration of the DMIC in the device, and includes information about clocks, resets, and hardware requests.

Figure 23-178 shows the DMIC integration.

**Figure 23-178. DMIC Integration**

**NOTE:** For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

The DMIC integration includes:

- One functional clock
- One interface clock
- One IRQ
- One sDMA/ADMA/eDMA request
- IDLE hardware handshake
- Wake-up request

[Table 23-508](#) through [Table 23-510](#) summarize the integration of the module in the device.

**Table 23-508. Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
DMIC	PD_AUDIO	N/A	L4_ABE

DMA Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
DMIC	DMIC_DMA	S_DMA_66	sDMA	DMA request to the system DMA (sDMA)
	DMIC_DMA	A_DMA_1	ADMA	DMA request to the audio DMA (ADMA)
	DMIC_DMA	D_DMA_44	eDMA	DMA request to the DSP DMA (eDMA)

**NOTE:**

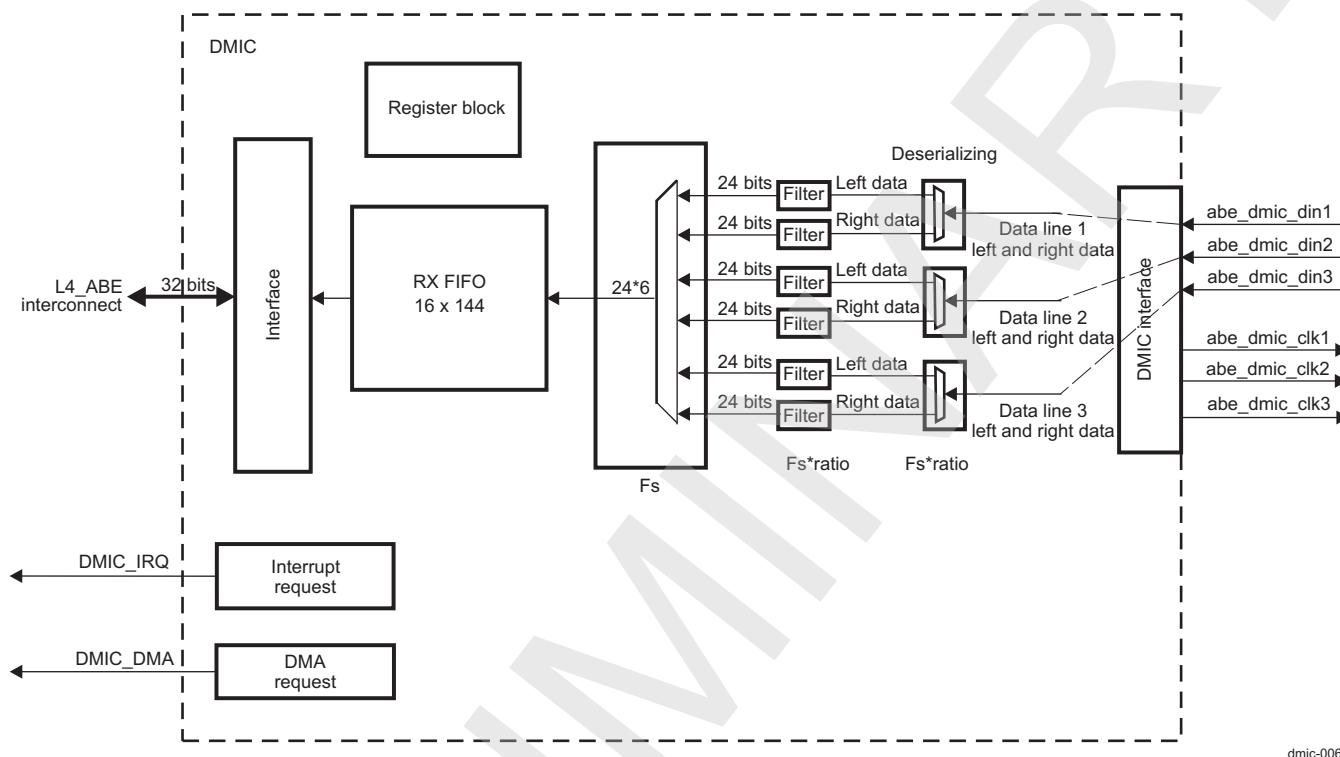

- For a description of the interrupt source, see [Section 23.7.4.5, Interrupt Requests](#).
- For a description of the DMA source, see [Section 23.7.4.6, DMA Requests](#).
- For information about PRCM clock gating and management and PRCM reset sources and distribution, see [Section 3.1.1.2.1, Power Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

## 23.7.4 DMIC Functional Description

### 23.7.4.1 Block Diagram

Figure 23-179 is the DMIC block diagram.

Figure 23-179. DMIC Block Diagram

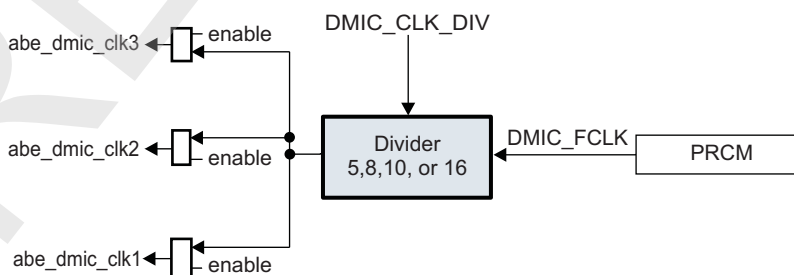

dmic-006

### 23.7.4.2 DMIC Clock Configuration

The DMIC operates from one interface clock to interface with the L4-ABE interconnect and one selectable (among three) functional clock. These clocks are provided by the PRCM module. For the interface clock, request and acknowledge are set up between the PRCM module and the DMIC.

Figure 23-180 shows the DMIC clock selection.

Figure 23-180. DMIC Clock Selection

dmic-007

DMIC\_FCLK is the source clock signal. Several source clocks are available and are selected according to the configuration of the `DMIC_CTRL[9:7]` DMIC\_CLK\_DIV bit field. For more information about

DMIC\_FCLK selection, see [Figure 23-180](#). `abe_dmic_clkx` are the output clocks generated in the DMIC and are fed to the external microphones. They are also the internal clocks of the external microphones. The performance in terms of signal-to-noise ratio (SNR) depends on these clocks. Users must take care about the value of `abe_dmic_clkx` (the analog-to-digital converter [ADC] clock) when selecting the source clock (DMIC\_FCLK). [Table 23-511](#) describes the `abe_dmic_clkx` generation.

**Table 23-511. `abe_dmic_clkx` Generation**

DMIC_FCLK	DMIC_CLK_DIV	DMIC_FCLK/ <code>abe_dmic_clk</code>	<code>abe_dmic_clk</code> = ADC Clock	Ratio = <code>abe_dmic_clk</code> /FS = 48 kHz
19.2 MHz	000	8	2.4 MHz	50
	001	5	3.84 MHz	80
24 MHz	010	10	2.4 MHz	50
24.576 MHz	011	8	3.072 MHz	64
	100	16	1.536 MHz	32
12 MHz	101	5	2.4 MHz	50

The maximum clock on the interface is 3.84 MHz, with a source clock of 19.2 MHz.

### 23.7.4.3 DMIC Software Reset

[Table 23-512](#) lists the different types of software reset available at the module level.

**Table 23-512. Reset Description**

Type	Name	Source	Description
Software	<code>DMIC_SYSCONFIG</code> [1] SOFTRESET	–	Module software reset
Software	<code>DMIC_CTRL</code> [10] SW_DMIC_RST	–	Reset-enabled DMIC paths

The software path reset is gated by:

- `DMIC_CTRL`[0] `DMIC_UP1_EN` for path 1
- `DMIC_CTRL`[1] `DMIC_UP2_EN` for path 2
- `DMIC_CTRL`[2] `DMIC_UP3_EN` for path 3
- `DMIC_CTRL`[10] SW\_DMIC\_RST

When the `DMIC_CTRL`[10] SW\_DMIC\_RST bit is set to 1, the corresponding enabled DMIC paths are reset. Resets are cleared by writing 0.

**NOTE:** A software reset is required to change the configuration of enabled paths; for example, to disable path 3, a software reset of path 3 is mandatory for the change to be considered.

A module software reset can be performed by setting the `DMIC_SYSCONFIG`[1] SOFTRESET bit. This action starts a soft reset sequence.

The software reset status of the module can be checked by reading the `DMIC_SYSCONFIG`[0] SOFTRESET bit (0: reset is done; 1: reset is ongoing).

### 23.7.4.4 DMIC Power Management

[Table 23-513](#) describes the power-management features available for the DMIC.

**Table 23-513. Local Power-Management Features**

Feature	Registers	Description
Clock autogating	N/A	Feature not available
Slave idle modes	<code>DMIC_SYSCONFIG</code> [3:2] SIDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available

**Table 23-513. Local Power-Management Features (continued)**

Feature	Registers	Description
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	<a href="#">DMIC_IRQWAKEEN</a> [0] IRQ_WAKEUP_EN <a href="#">DMIC_DMAWAKEEN</a> [0] DMA_WAKEUP_EN	This register holds one active-high enable bit per event source that can generate a wake-up signal.

#### 23.7.4.5 DMIC Interrupt Requests

[Figure 23-181](#) lists the event flags, and their mask, that can cause module interrupts.

Table 23-514. Interrupt Events

Nonmaskable Event Flag <sup>(1)</sup>	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
DMIC_IRQSTATUS_RAW[3] DMIC_IRQ_EMPTY	DMIC_IRQSTATUS[3] DMIC_IRQ_EMPTY	DMIC_IRQENABLE_CLR[3] DMIC_IRQ_EMPTY_MASK	DMIC_IRQENABLE_SET[3] DMIC_IRQ_EMPTY_MASK	FIFO empty event. This event occurs when the FIFO is already empty and a new word is read from the FIFO by software.
DMIC_IRQSTATUS_RAW[2] DMIC_IRQ_ALST_FULL	DMIC_IRQSTATUS[2] DMIC_IRQ_ALST_FULL	DMIC_IRQENABLE_CLR[2] DMIC_IRQ_ALST_FULL_MASK	DMIC_IRQENABLE_SET[2] DMIC_IRQ_ALST_FULL_MASK	FIFO almost-full event. This event occurs when the FIFO contains (FIFO size – 1) words and a new word is written to the FIFO.
DMIC_IRQSTATUS_RAW[1] DMIC_IRQ_FULL	DMIC_IRQSTATUS[1] DMIC_IRQ_FULL	DMIC_IRQENABLE_CLR[1] DMIC_IRQ_FULL_MASK	DMIC_IRQENABLE_SET[1] DMIC_IRQ_FULL_MASK	FIFO full event. This event occurs when the FIFO is already full and a new word is written to the FIFO.
DMIC_IRQSTATUS_RAW[0] DMIC_IRQ	DMIC_IRQSTATUS[0] DMIC_IRQ	DMIC_IRQENABLE_CLR[0] DMIC_IRQ_MASK	DMIC_IRQENABLE_SET[0] DMIC_IRQ_MASK	FIFO read request event. This event occurs when the number of words stored in the FIFO is equal to or greater than the FIFO threshold.

<sup>(1)</sup> The [DMIC\\_IRQSTATUS\\_RAW](#) register is used primarily for debug purposes.

The interrupt line is asserted (active high) when one of the following signals appears:

- DMIC\_IRQ\_EMPTY
- DMIC\_IRQ\_ALST\_FULL
- DMIC\_IRQ\_FULL
- DMIC\_IRQ

Read the [DMIC\\_IRQSTATUS](#) register to determine which event occurs.

**CAUTION**

Interrupt lines must be cleared by software. Write 1 in the [DMIC\\_IRQSTATUS](#) register to clear the corresponding event.

An event can generate an IRQ when the corresponding mask bit in the [DMIC\\_IRQENABLE\\_SET](#) register is set to 1. Events are register bits that belong to the [DMIC\\_IRQSTATUS](#) and [DMIC\\_IRQSTATUS\\_RAW](#) registers (the same register accessed by two interconnect addresses). In the case of the [DMIC\\_IRQSTATUS\\_RAW](#) register, status event is set even if it is not enabled (used primarily for debug purposes). The [DMIC\\_IRQSTATUS](#) register is set by writing 1 to the [DMIC\\_IRQSTATUS\\_RAW](#) register.

Each internal interrupt signal can be masked by enabling the corresponding mask in the [DMIC\\_IRQENABLE\\_SET](#) register or disabling it in the [DMIC\\_IRQENABLE\\_CLR](#) register. This mechanism is defined in [Section 23.7.6, DMIC Register Manual](#).

[Figure 23-181](#) shows the interrupt tree with the event generated and the mask that enables or disables the event. All events are summarized to give the single interrupt generation.

Figure 23-181. Interrupt Tree

dmic-008

#### 23.7.4.6 DMIC DMA Requests

The DMIC can generate one DMA request to the sDMA, ADMA, and eDMA controllers (see [Table 23-515](#)).

**Table 23-515. DMIC DMA Request**

Name	Description	Enable DMA Bit	Disable DMA Bit
DMIC_DMA_ENABLE	Data ready in FIFO (threshold is reached)	<a href="#">DMIC_DMAENABLE_SET</a> [0] DMA_ENABLE	<a href="#">DMIC_DMAENABLE_CLR</a> [0] DMA_ENABLE

The DMA lines can be enabled or disabled depending on the value of the bits in the [DMIC\\_DMAENABLE\\_SET](#) and [DMIC\\_DMAENABLE\\_CLR](#) registers.

A DMA request is sent when data is ready in the FIFO. This request is used only to notify the host that data are ready in the FIFO.

### 23.7.4.7 Audio Data Processing

The DMIC supports six audio paths and can be used with three stereo or six mono microphones. Each path is independent and is enabled or disabled by using the following bits:

- [DMIC\\_CTRL](#)[0] DMIC\_UP1\_EN
- [DMIC\\_CTRL](#)[1] DMIC\_UP2\_EN
- [DMIC\\_CTRL](#)[2] DMIC\_UP3\_EN

#### 23.7.4.7.1 Filtering

The external DMIC generates a PDM stream of bits and transfers it in one period or one half-period of the clock provided by the DMIC inside the device. The aim of the DMIC audio path is to process data from the DMIC interface, decimate and filter the data, and store the processed data in the FIFO.

The format of the DMIC data is 24 bits (the transfer format is 32 bits long). The following bits allow switching the polarity of the interface:

- [DMIC\\_CTRL](#)[4] DMIC\_POLAR1
- [DMIC\\_CTRL](#)[5] DMIC\_POLAR2
- [DMIC\\_CTRL](#)[6] DMIC\_POLAR3

For more information, see [Section 23.7.2.1.3.1](#), *DMIC Clock Generation and Synchronization*.

Processed data from the DMIC interface are stored in the FIFO. The FIFO is controlled by the IRQ and DMA request and externally fed by the DMIC using the following interconnect format.

The three uplink paths are identical. Each uplink path is composed of a left and a right channel. The DMIC interface delivers six parallel data of 1 bit (3 × 2 paths of stereo data that can be used at six mono paths). Each bit goes to a filter. The aim of the filter is to limit the noise and perform decimation by factor D. Factor D depends on the [DMIC\\_CLK\\_DIV](#) register bits, as described in the ratio defined in [Table 23-511](#). The filters are sinc filter order 4. They are chosen with regard to the nature of the analog converter.

The format of the filter output is 24 bits.

### 23.7.4.8 FIFO Management

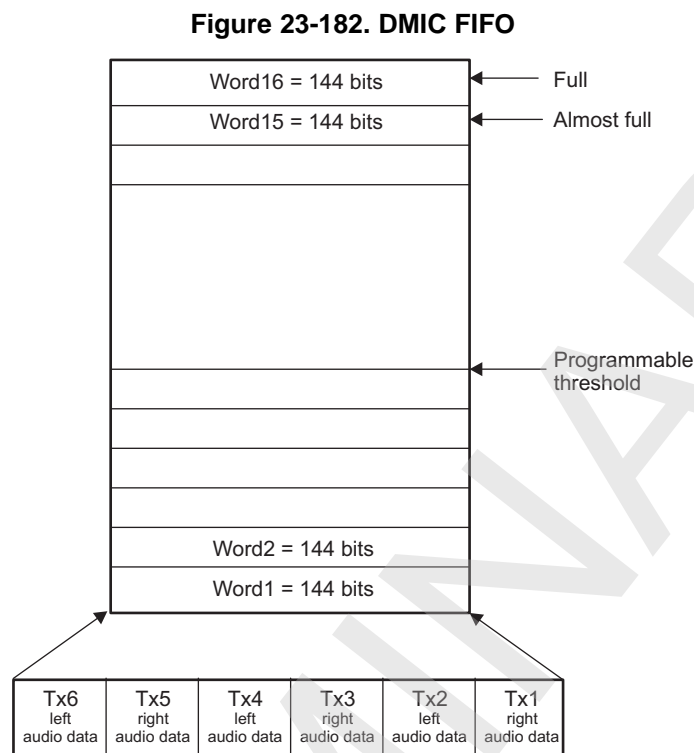

The DMIC implements an internal FIFO controlled by IRQ and DMA request. The host must read words in the FIFO. The interrupt line is used not only to inform the host that data are ready in the FIFO, but also to warn the host about events that can occur, such as FIFO full, almost full, or empty. A DMA request is used only to inform the host that data are ready in the FIFO.

#### 23.7.4.8.1 FIFO General Description

The DMIC communicates with the host through L4-ABE interconnect access. DMIC audio data coming from external microphones are stored in the FIFO. The DMIC FIFO allows the exchange of information between the DMIC and the host. Each audio data is 24 bits long. The DMIC FIFO contains 16 words. Each word is the combination of six audio data (24 × 6 = 144 bits) coming from the interface. The FIFO is controlled by interrupt lines and DMA requests. For more information about IRQs and DMA controls, see [Section 23.7.4.5](#), *DMIC Interrupt Requests*, and [Section 23.7.4.6](#), *DMIC DMA Requests*.

FIFO write access is done in the functional clock domain, and read access is done in the interface clock domain.

Figure 23-182 is an overview of the DMIC FIFO.

### 23.7.4.8.2 FIFO Operations

Audio data are filled in the FIFO from DMIC internal filters. The host must read words in the FIFO. The number of reads depends on the application that is configured by the following bits:

- [DMIC\\_CTRL\[0\]](#) DMIC\_UP1\_EN
- [DMIC\\_CTRL\[2\]](#) DMIC\_UP3\_EN
- [DMIC\\_CTRL\[1\]](#) DMIC\_UP2\_EN
- [DMIC\\_FIFO\\_CTRL\[3:0\]](#) DMIC\_TRESH (FIFO threshold)

If only uplink path 2 and path 3 are enabled, for example, the Tx1 and Tx2 words are left and right data for path 2, and Tx3 and Tx4 are left and right data for path 3.

When the FIFO threshold is reached, and depending on conditions, an event is sent to the DMA handler. The host must read the exact number of words in the FIFO.

Two accesses are required to read a complete stereo audio path.

The number of read accesses from the host is determined by the following equation:

$$\text{Num\_rd\_access} = (\text{DMIC\_UP1\_EN} + \text{DMIC\_UP2\_EN} + \text{DMIC\_UP3\_EN}) \times 2 \times (\text{DMIC\_TRESH})$$

The FIFO threshold is programmed through the [DMIC\\_FIFO\\_CTRL\[3:0\]](#) DMIC\_TRESH bit field.

---

**NOTE:** If DMIC\_TRESH = 1, the host is expected to perform  $1 \times (\text{DMIC\_UP1\_EN} + \text{DMIC\_UP2\_EN} + \text{DMIC\_UP3\_EN}) \times 2$  read access every 96 kHz ( $2 \times \text{FS}$ ).

If DMIC\_TRESH = 2, the host is expected to perform  $(\text{DMIC\_UP1\_EN} + \text{DMIC\_UP2\_EN} + \text{DMIC\_UP3\_EN}) \times 4$  read access every 48 kHz (FS).

If DMIC\_TRESH = 12, the host is expected to perform  $(\text{DMIC\_UP1\_EN} + \text{DMIC\_UP2\_EN} + \text{DMIC\_UP3\_EN}) \times 12$  access every 8 kHz ( $\text{FS}/6$ ).

---

### 23.7.4.8.3 FIFO Output Range Definition

The [DMIC\\_CTRL\[3\]](#) DMICOUTFORMAT bit allows determining the format of the output of the DMIC uplink module.

When DMICOUTFORMAT = 0, the data going from the FIFO are left-shifted by 8 bits. When DMICOUTFORMAT = 1, the data are signed-extended on 32 bits.

The DMIC uplink modules process audio data based on twos complement format.

---

**NOTE:** When DMICOUTFORMAT = 0, the maximum positive swing analog voltage corresponds to a final DMIC output of 0x7FFF FF00. The maximum negative swing analog voltage corresponds to a final DMIC output of 0x8000 0000.

When DMICOUTFORMAT = 1, the sign is extended: The maximum positive swing analog voltage corresponds to a final DMIC output of 0x007F FFFF. The maximum negative swing analog voltage corresponds to a final DMIC output of 0xFF80 0000.

---

Reading the value of the corresponding audio data in the FIFO requires access to the [DMIC\\_DATA\\_REG](#) register. The first access gives the value of Tx1 right data, the second gives the value of Tx2 left data, up to Tx6 (the left audio data of the last audio path). If the path is disabled, 0x0 is read. All data are duplicated (for debug purposes) in their corresponding left or right data registers. [Table 23-516](#) describes the audio data path registers.

**Table 23-516. Audio Data Path Registers**

Stereo Audio Path	Mono Audio Path	Data Register
Right path 1	Mono path 1	<a href="#">DMIC_FIFO_DMIC1R_DATA[23:0]</a>
Left path 1	Mono path 2	<a href="#">DMIC_FIFO_DMIC1L_DATA[23:0]</a>
Right path 2	Mono path 3	<a href="#">DMIC_FIFO_DMIC2R_DATA[23:0]</a>
Left path 2	Mono path 4	<a href="#">DMIC_FIFO_DMIC2L_DATA[23:0]</a>
Right path 3	Mono path 5	<a href="#">DMIC_FIFO_DMIC3R_DATA[23:0]</a>
Left path 3	Mono path 6	<a href="#">DMIC_FIFO_DMIC3L_DATA[23:0]</a>

The output of the DMIC path for interconnect access is in 32-bit format.

## 23.7.5 DMIC Programming Guide

### 23.7.5.1 DMIC Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

#### 23.7.5.1.1 Global Initialization

##### 23.7.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the DMIC is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the DMIC. For more information, see [Section 23.7.3, DMIC Integration](#) and [Section 23.7.2, DMIC Environment](#).

[Table 23-517](#) describes the global initialization of surrounding modules.

**Table 23-517. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. See <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Control module	Module-specific pad muxing must be set in the control module. See <a href="#">Chapter 18 Control Module</a> .
(optional) Cortex-A9 MPU interrupt controller (INTC) (or DSP INTC)	INTC configuration must be done to enable the interrupts from the DMIC. See <a href="#">Chapter 17, Interrupt Controllers</a> .
(optional) sDMA (or eDMA or ADMA)	DMA configuration must be done to enable the DMIC DMA channel requests.
(optional) Interconnect	For more information about the interconnect configuration, see <a href="#">Chapter 13, Interconnect</a> .

**NOTE:** The INTC and DMA configurations are necessary if the interrupt and DMA-based communication modes are used.

#### 23.7.5.1.1.2 DMIC Global Initialization

##### 23.7.5.1.1.2.1 Main Sequence – DMIC Global Initialization

The procedure in [Table 23-518](#) initializes the DMIC after a power-on reset (POR).

**Table 23-518. DMIC Global Initialization**

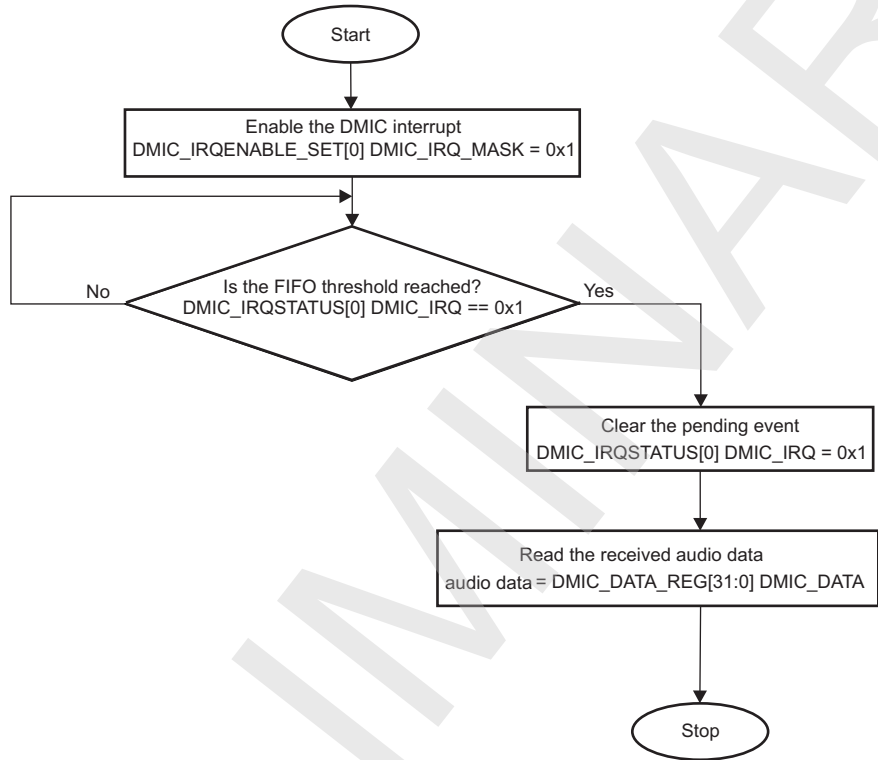

Step	Register/Bit Field/Programming Model	Value
Execute a software reset.	DMIC_SYSCONFIG[0] SOFTRESET	0x1
Wait for the software reset completion by polling.	DMIC_SYSCONFIG[0] SOFTRESET	==0x0
Configure the local power management.	DMIC_SYSCONFIG[3:2] SIDLEMODE	0x-
Select the DMIC FIFO threshold.	DMIC_FIFO_CTRL[3:0] DMIC_TRESH	0x-
Select the DMIC output clock frequency.	DMIC_CTRL[9:7] DMIC_CLK_DIV	0x-
Select the DMIC FIFO data output format.	DMIC_CTRL[3] DMICOUTFORMAT	0x-
Select the level (high or low) of the clock signal <code>abe_dmic_clk_i</code> when the left data is to be generated (extracted) from the external microphone <code>i</code> (where <code>i = 1 to 3</code> ).	DMIC_CTRL[j] DMIC_POLAR <sub>i</sub> (where <code>j = 4 to 6</code> , and <code>i = 1 to 3</code> )	0x-
Enable audio path <code>i</code> (where <code>i = 1 to 3</code> ).	DMIC_CTRL[k] DMIC_POLAR <sub>i</sub> (where <code>k = 0 to 2</code> , and <code>i = 1 to 3</code> )	0x1

23.7.5.1.2 Operational Mode Configuration

23.7.5.1.2.1 DMIC Polling Mode

Figure 23-183 shows the polling mode. Table 23-519 summarizes the register call for the polling mode. For the number of read accesses used while reading the received audio data, see Section 23.7.4.8, FIFO Management.

Figure 23-183. Polling Mode

dmic-010

Table 23-519. Register Call Summary for Polling Mode

Register Name	Register Name	Register Name
DMIC_IRQENABLE_SET	DMIC_IRQSTATUS	DMIC_DATA_REG

23.7.5.1.2.2 DMIC Interrupt Mode

Table 23-520 lists the procedure to initialize interrupt mode.

Table 23-520. Interrupt Mode

Step	Register/Bit Field/Programming Model	Value
Enable the DMIC interrupts.	DMIC_IRQENABLE_SET[3:0]	0xF

23.7.5.1.2.3 DMIC DMA Mode

Table 23-521 lists the procedure to initialize DMA mode.

Table 23-521. DMA Mode

Step	Register/Bit Field/Programming Model	Value
Enable the DMIC DMA interrupt event.	DMIC_DMAENABLE_SET[0] DMA_ENABLE	0x1

### 23.7.5.1.3 DMIC Events Servicing

#### 23.7.5.1.3.1 DMIC Interrupt Servicing

This section describes the interrupt event servicing of the module. Figure 23-184 shows the interrupt handler.

**Figure 23-184. Interrupt Handler**

dmic-011

When the interrupt is caused by the reached threshold event, for the number of read accesses used while reading the received audio data, see Section 23.7.4.8, *FIFO Management*.

When the interrupt is caused by a FIFO full or almost-full event, software must read all the available data in the FIFO. If a FIFO full event occurred, the number of read accesses must be the maximum:

$$\text{Num\_rd\_access} = (\text{DMIC\_UP1\_EN} + \text{DMIC\_UP2\_EN} + \text{DMIC\_UP3\_EN}) \times 2 \times 15$$

If a FIFO almost-full event occurred, the number of read accesses must be:

$$\text{Num\_rd\_access} = (\text{DMIC\_UP1\_EN} + \text{DMIC\_UP2\_EN} + \text{DMIC\_UP3\_EN}) \times 2 \times 14$$

Table 23-522 summarizes the register call for the interrupt handler.

**Table 23-522. Register Call Summary for the Interrupt Handler**

Register Name	Register Name
DMIC_IRQSTATUS	DMIC_DATA_REG

PRELIMINARY

## 23.8 Multichannel Audio Serial Port

This section describes the multichannel audio serial port (McASP).

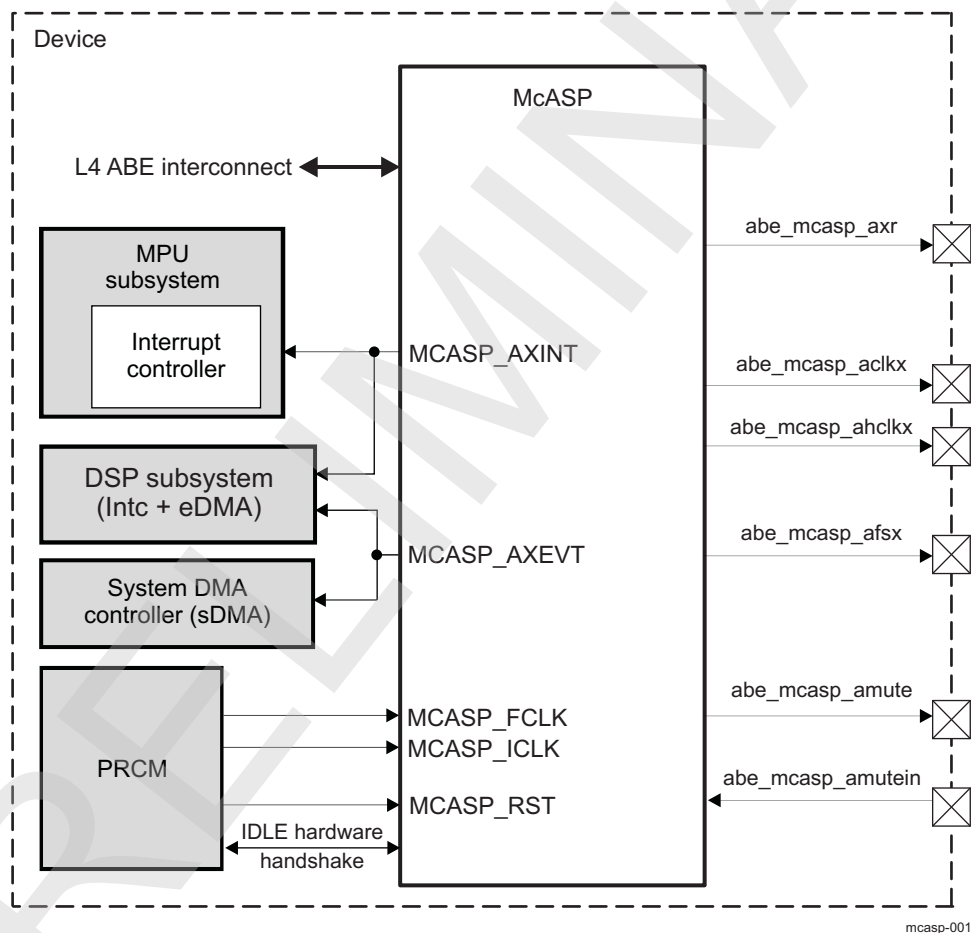

### 23.8.1 McASP Overview

This section introduces the multichannel audio serial port (McASP) module and describes its main functions and connections in the device.

The McASP functions as a general-purpose audio serial port optimized to the requirements of various audio applications. The McASP is useful for intercomponent digital audio interface transmission (DIT). The McASP has the flexibility to gluelessly connect to a Sony/Philips digital interface (S/PDIF) transmit physical layer component. The McASP module operates in transmit mode only; it has no receive capabilities.

Figure 23-185 shows the McASP module in the device.

**Figure 23-185. McASP Module**

The McASP module includes the following main features:

- Support of the idle request/acknowledge protocol
- Buffer for transmit operations
- One transmit direct memory access (DMA) request linked with a 32-bit register, and one transmit interrupt request
- One transmit channel
- One serializer

## 23.8.2 McASP Environment

This section describes the McASP application fields from an environment point of view (external connections), along with the McASP connectivity options. This section also lists all of the possible interfaces and describes the protocol and data format used in each case.

### 23.8.2.1 McASP Signals

Table 23-563 describes the McASP signals and specifies their links to functions.

**Table 23-563. I/O**

Signal	I/O <sup>(1)</sup>	Description
abe_mcasp_axr	O	Audio transmit data
abe_mcasp_aclkx	O	Transmit bit clock
abe_mcasp_ahclkx	O	Transmit high-frequency master clock
abe_mcasp_afsx	O	Transmit frame synchronization
abe_mcasp_amute	O	Mute out to external
abe_mcasp_amutein	I	Mute in from external

<sup>(1)</sup> I = Input; O = Output

All McASP pins on the device can be individually programmed as general-purpose input/output (GPIO) if they are not used for serial port functions.

The McASP includes the following pins:

- Serializer:
  - Data pin abe\_mcasp\_axr
- Transmit clock generator:
  - abe\_mcasp\_aclkx: McASP transmit bit clock
  - abe\_mcasp\_ahclkx: McASP transmit high-frequency master clock
- Transmit frame-sync generator:
  - abe\_mcasp\_afsx: McASP transmit frame sync
- Mute in/out:
  - abe\_mcasp\_amutein: McASP mute input (from external device)
  - abe\_mcasp\_amute: McASP mute output

### 23.8.2.2 Protocols and Data Formats

#### 23.8.2.2.1 Protocols Supported

The McASP transmit section uses the S/PDIF industry format, which is supported by the DIT transfer mode of the module.

Each transmit section can be programmed to support the following options on the basic serial protocol:

- Programmable clock and frame-sync polarity (rising or falling edge): abe\_mcasp\_aclkx, abe\_mcasp\_ahclkx, and abe\_mcasp\_afsx
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length
- First-bit data delay: 0-, 1-, 2-bit clocks
- Left/right alignment of word inside slot
- Bit order: Most-significant bit (MSB) first or least-significant bit (LSB) first
- Bit mask/pad/rotate function
- Automatically aligns data in Q31 or integer format
- Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit)

The DIT transfer mode includes the following additional transmitter features:

- Transmit-only mode: 384 time slots (subframe) per frame
- Biphase encoded LVCMOS output
- Channel status RAM (384 bits)
- User data RAM (384 bits)
- Separate valid bit (V) for subframes A and B

---

**NOTE:** An external transceiver must be connected to the McASP port in the device to translate the electrical signals delivered by the McASP (1.2 V or 1.8 V LVCMOS levels) to the electrical levels of the S/PDIF standard.

---

### 23.8.2.2.2 Definition of Terms

The serial bit stream transmitted by the McASP is a long sequence of 1s and 0s on an audio transmit pin (`abe_mcasp_axr`). However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. [Figure 23-186](#) shows two of the three basic components: the clock (`abe_mcasp_aclkx`) and the data (`abe_mcasp_axr`). In operation, the transmitter uses `abe_mcasp_aclkx` as serial clock.

- Bit:

A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A 1 is represented by a logic high on the `abe_mcasp_axr` pin for the entire duration of the bit. A 0 is represented by a logic low on the `abe_mcasp_axr` pin for the entire duration of the bit.

- Word:

A word is a group of bits that make up the data being transferred between the McASP and the external device. [Figure 23-186](#) shows an 8-bit word.

- Slot:

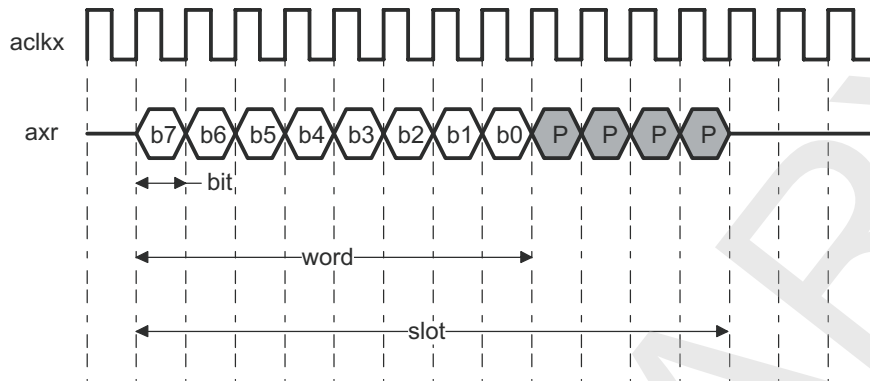

A slot consists of the bits that make up the word and can consist of additional bits used to pad the word to a convenient number of bits for the interface between the McASP and the external device. In [Figure 23-186](#), the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with four 0s (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits can be shifted out of the McASP on the `abe_mcasp_axr` pin with either MSB or LSB first.

When the word size is smaller than the slot size, the word can be aligned to the left of the slot (beginning) or to the right of the slot (end). The additional bits in the slot not belonging to the word can be padded with 0, 1, or with one of the bits (typically, the MSB or LSB) from the data word.

[Figure 23-187](#) shows these options.

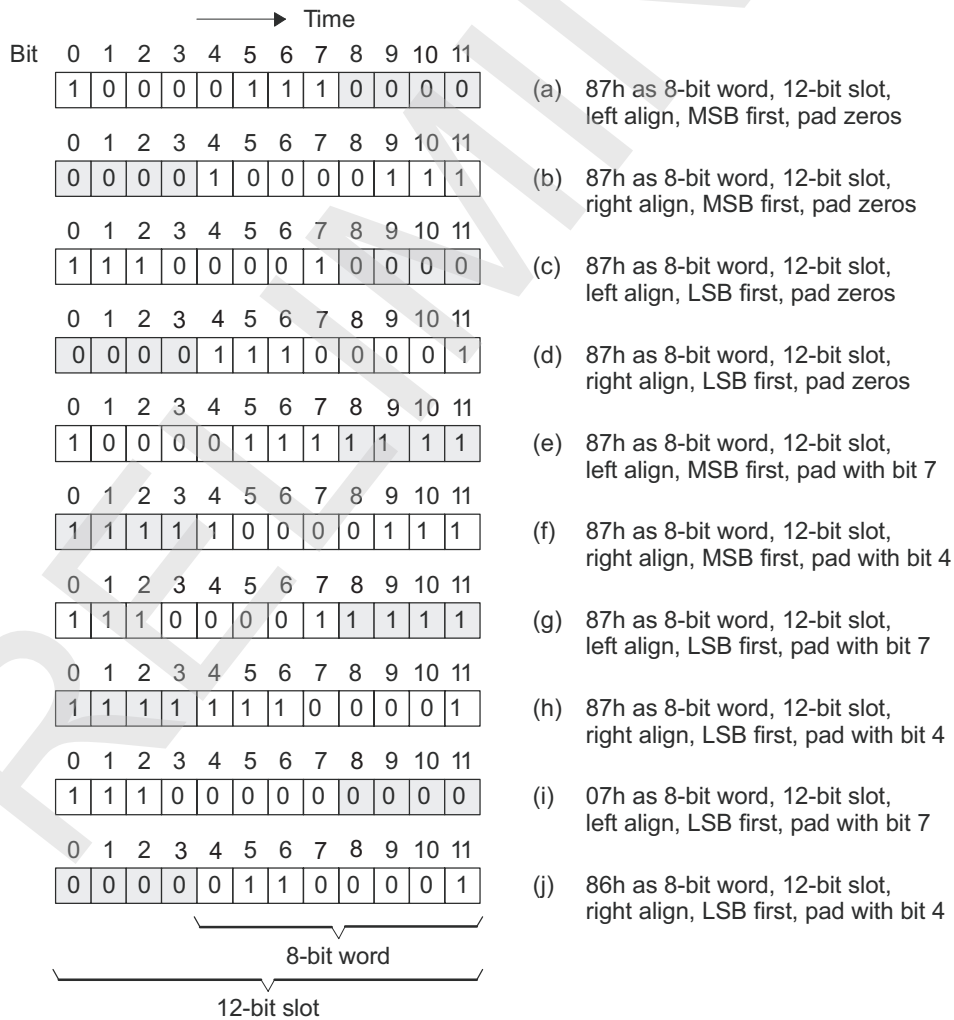

Figure 23-186. Definition of Bit, Word, and Slot

- (1) b7:b0 - bits. Bits b7 to b0 form a word.
- (2) P - pad bits. Bits b7 to b0, together with the 4 pad bits, form a slot.
- (3) In this example, the data is transmitted MSB first, left-aligned.

mccasp-010

Figure 23-187. Bit Order and Word Alignment Within a Slot Examples

- Unshaded: bit belongs to word
- Shaded: bit is a pad bit

mccasp-008

- Frame

The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this document. A frame contains one or multiple slots, as determined by the desired protocol. [Figure 23-188](#) shows an example frame of data and the frame definitions. In operation, the transmitter uses `abe_mcaspx_axr`. This example shows two slots in a frame and the frame-sync (FS) duration of the slot length.

This section shows only the generic definition of the frame sync. For more information about the frame-sync formats required for the transfer modes and protocols (DIT mode and S/PDIF format), see [Section 23.8.2.2.3, Frame Format](#).

**Figure 23-188. Definition of Frame and Frame-Sync Width**

The following terms are used throughout this chapter:

- DIT: Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on the `abe_mcaspx_axr` data pin.
- Slot or time slot: For DIT format, a McASP time slot corresponds to a DIT subframe.

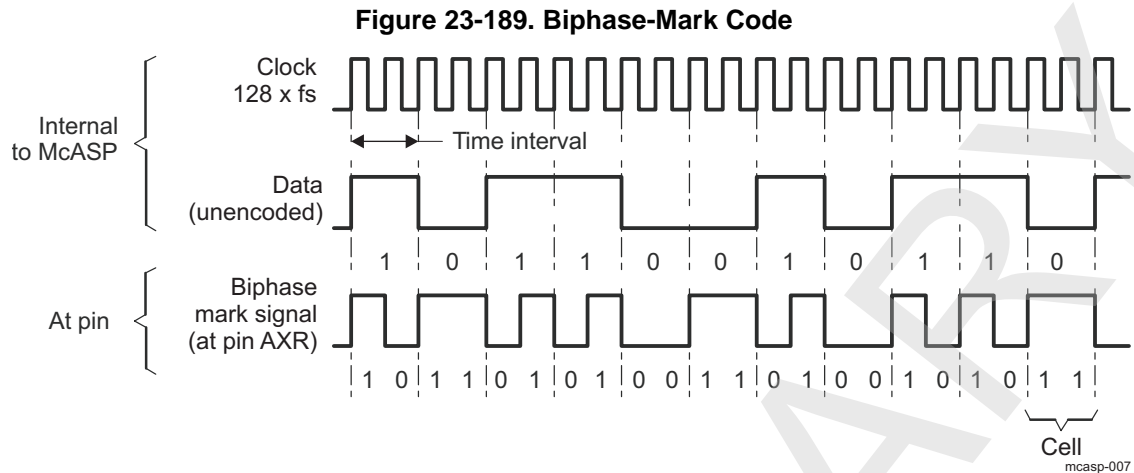

### 23.8.2.2.3 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 3.3-V biphasemark encoded output. The S/PDIF format is supported by the DIT transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

#### 23.8.2.2.3.1 Biphasemark Code

In S/PDIF format, the digital signal is coded using the biphasemark code (BMC). The clock, frame, and data are embedded in only one signal: data pin `abe_mcaspx_axr`. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. [Figure 23-189](#) and [Table 23-564](#) show how data is encoded to the BMC format.

As shown in [Figure 23-189](#), the clock frequency is twice the unencoded data bit rate. In addition, the clock is always programmed to  $128 \times f_s$ , where  $f_s$  is the sample rate (see [Section 23.8.2.2.3.3, Frame Format](#), for details on how this clock rate is derived based on the S/PDIF format).

**Table 23-564. Biphase-Mark Encoder**

Data (Unencoded)	Previous State at Pin abe_mcasep_axr	BMC-Encoded Cell Output at abe_mcasep_axr
0	0	11
0	1	00
1	0	10
1	1	01

**23.8.2.2.3.2 Subframe Format**

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered 0 to 31. [Figure 23-190](#) shows a subframe.

- Time intervals 0–3 carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is not encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See [Table 23-565](#).
- Time intervals 4–27 carry the audio sample word in linear 2s-complement representation. The MSB is carried by time interval 27. When a 24-bit coding range is used, the LSB is in time interval 4. When a 20-bit coding range is used, time intervals 8–27 carry the audio sample word with the LSB in time interval 8. Time intervals 4–7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field can carry any other information.
- Time interval 28 carries the validity bit (V) associated with the main data field in the subframe.
- Time interval 29 carries the user data channel (U) associated with the main data field in the subframe.
- Time interval 30 carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- Time interval 31 carries a parity bit (P) such that time intervals 4–31 carry an even number of 1s and an even number of 0s (even parity). As listed in [Table 23-565](#), the preambles (time intervals 0–3) are also defined with even parity.

**Figure 23-190. S/PDIF Subframe Format**

As listed in [Table 23-565](#), the McASP DIT generates only one polarity of preambles, and it assumes the previous logical state is 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the `abe_mcasp_axr` pin before continuing with the next transmission.

**Table 23-565. Preamble Codes**

Preamble Code <sup>(1)</sup>	Previous Logical State	Logical States on pin <code>abe_mcasp_axr</code> <sup>(2)</sup>	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

<sup>(1)</sup> Historically, preamble codes are referred to as B, M, and W. For use in professional applications, preambles are referred to as Z, X, and Y, respectively.

<sup>(2)</sup> The preamble is not BMC-encoded. Each logical state is synchronized to the serial clock. These eight logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

### 23.8.2.2.3.3 Frame Format

An S/PDIF frame is composed of two subframes (see [Figure 23-191](#)). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency  $f_s$ . The S/PDIF format clock rate is therefore  $128 \times f_s$  ( $128 = 32$  cells per subframe  $\times 2$  clocks per cell  $\times 2$  subframes per sample). For example, for an S/PDIF stream at a 192-kHz sampling frequency, the serial clock is  $128 \times 192$  kHz = 24.58 MHz.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data. The first subframe (left or A channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (right or B channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

**Figure 23-191. S/PDIF Frame Format**

### 23.8.3 McASP Integration

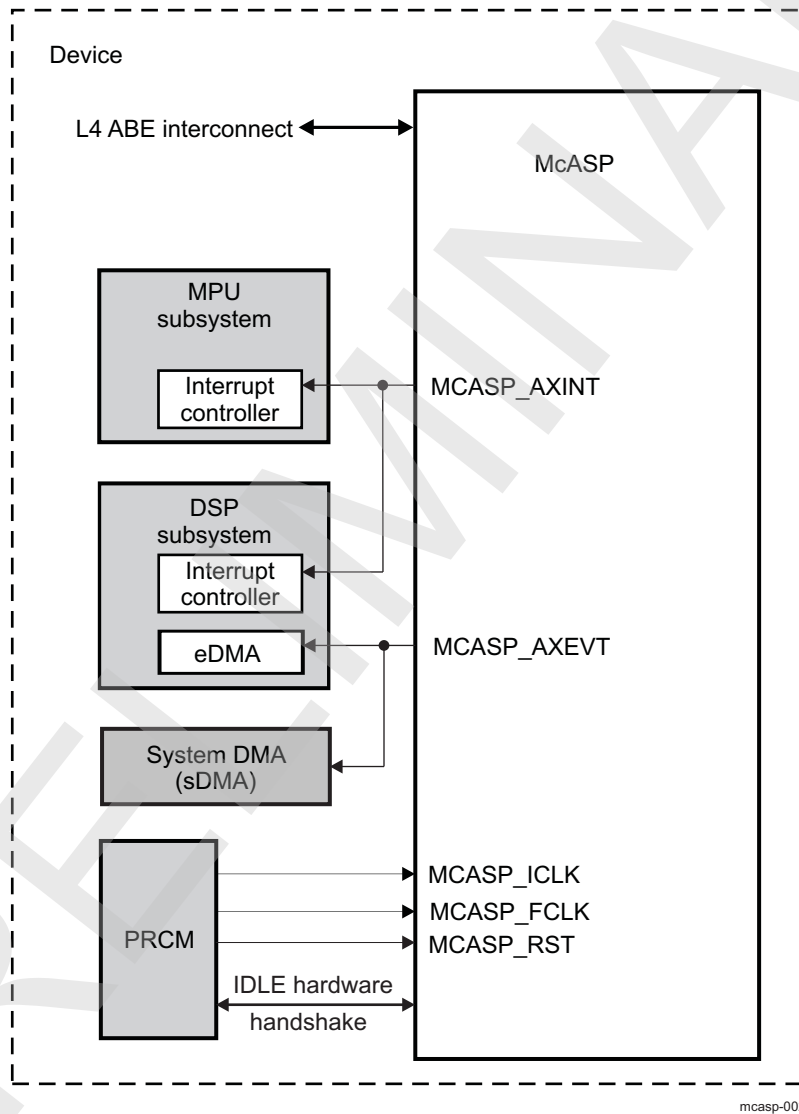

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

The McASP includes the following features:

- IDLE hardware handshake
- One DMA request
- One interrupt request (IRQ)

Figure 23-192 shows McASP integration.

Figure 23-192. McASP Integration

**NOTE:** For more information about the IDLE hardware handshake, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 23-566](#) through [Table 23-568](#) summarize the integration of the module in the device.

**Table 23-566. Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
McASP	PD_AUDIO	NO	L4_ABE

**Table 23-567. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
McASP	MCASP_ICLK	ABE_ICLK2	PRCM	McASP interface clock
	MCASP_FCLK	MCASP1_FCLK	PRCM	McASP functional clock
Resets				
McASP	MCASP_RST	AUDIO_RST	PRCM	AUDIO power domain reset

**Table 23-568. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
McASP	MCASP_AXINT	D_IRQ_92	DSP	McASP transmit interrupt
	MCASP_AXINT	MA_IRQ_109	Cortex™-A9	McASP transmit interrupt
DMA Requests				
McASP	MCASP_AXEVT	S_DMA_7	sDMA	McASP data transmit DMA request line to the system DMA (sDMA)
	MCASP_AXEVT	D_DMA_36	eDMA	McASP data transmit DMA request line to the DSP DMA (eDMA)

**NOTE:**

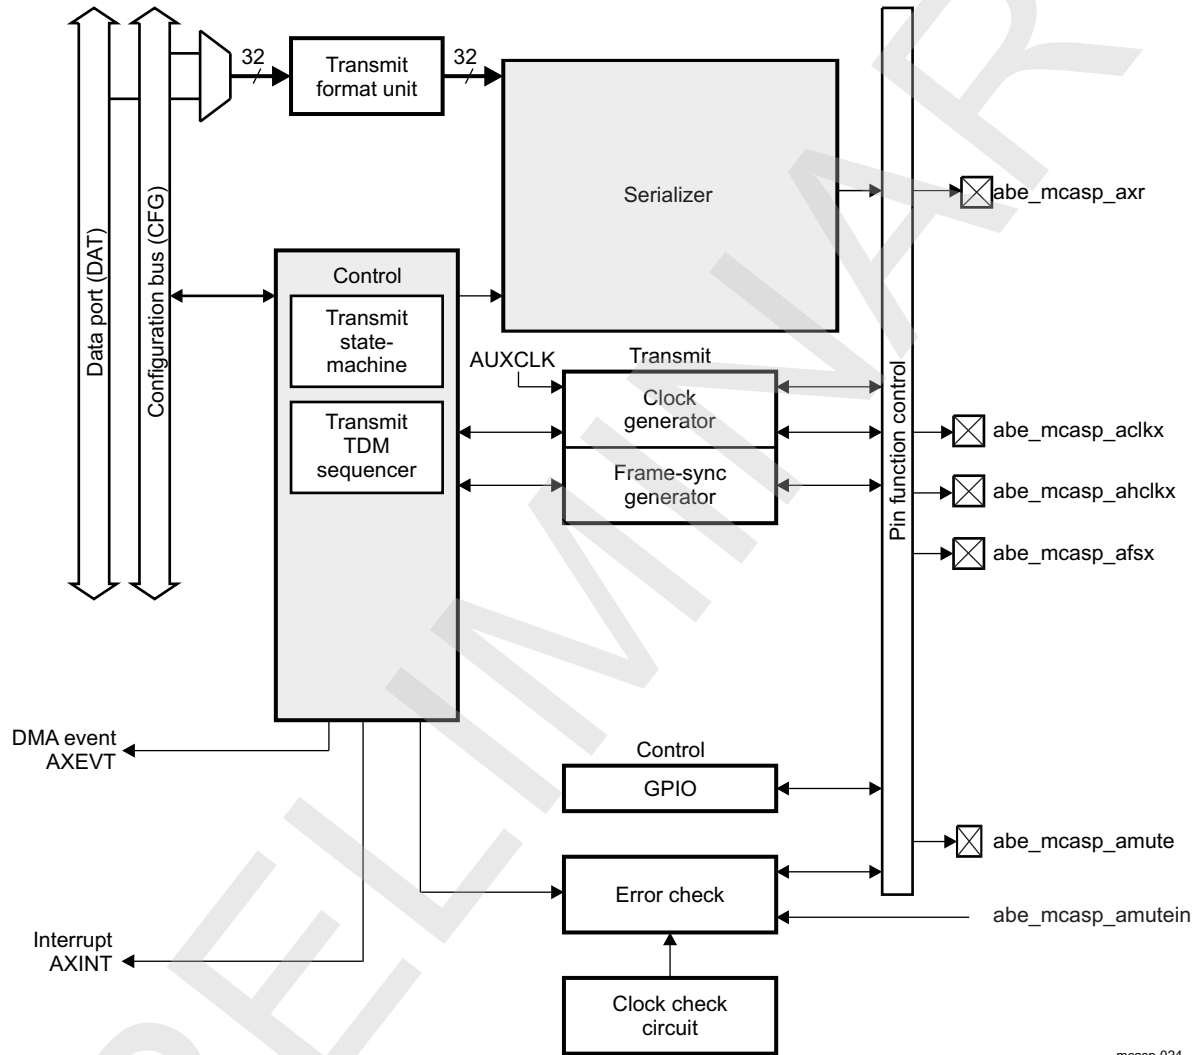

- For the description of the interrupt source, see [Section 23.8.4.11, Interrupt Requests](#).
- For the description of the DMA source, see [Section 23.8.4.12, DMA Requests](#).

### 23.8.4 McASP Functional Description

#### 23.8.4.1 Block Diagram

Figure 23-193 shows the major blocks of the McASP. The McASP has a transmit clock generator and a frame-sync generator, serializer, format unit, and error-checking logic.

Figure 23-193. McASP Block Diagram

mcasp-024

#### 23.8.4.2 McASP Clock and Frame-Sync Configuration

The transmit serial clock (clock at the bit rate) can be sourced internally by passing through two clock dividers off the internal clock source (AUXCLK). The bit rate clock is generated internally and is driven out on the `abe_mcasp_aclkx` pin. An internally generated high-frequency clock can be driven out onto the `abe_mcasp_ahclkx` pin to serve as a reference clock for other components in the system.

##### 23.8.4.2.1 Transmit Clock

The transmit bit clock, `abe_mcasp_aclkx`, is generated internally. For this purpose, the `MCASP_ACLKXCTL[5]` CLKXM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the `MCASP_ACLKXCTL[4:0]` CLKXDIV bit field) from the source signal.

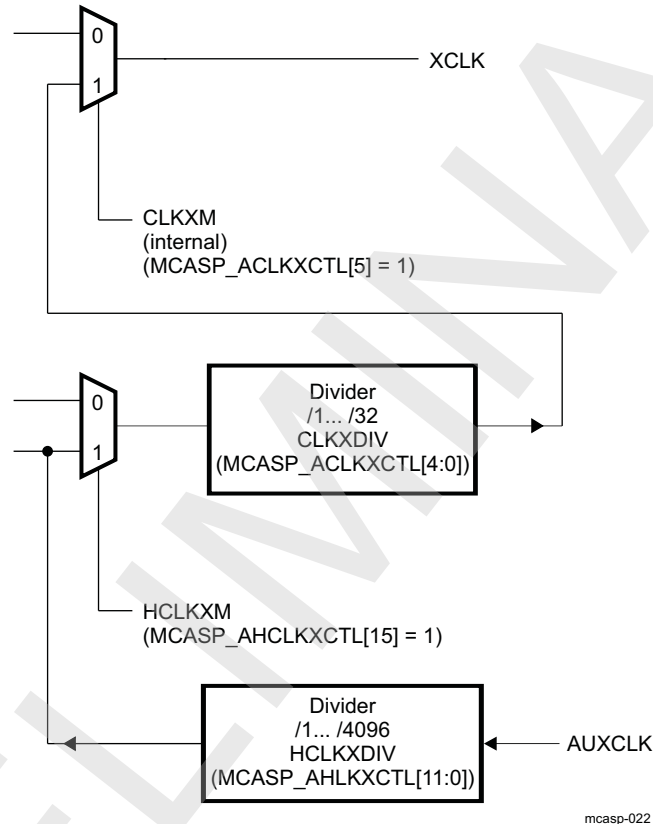

The transmit high-frequency master clock, `abe_mcasp_ahclkx`, is also generated internally. For this purpose, the `MCASP_AHCLKXCTL[15]` HCLKXM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the `MCASP_AHCLKXCTL[11:0]` HCLKXDIV bit field) from the McASP internal clock source AUXCLK.

The transmit clock configuration is controlled by the following registers:

- `MCASP_ACLKXCTL`
- `MCASP_AHCLKXCTL`

Figure 23-194 is the block diagram of the transmit clock generator.

**Figure 23-194. Transmit Clock Generator Block Diagram**

### 23.8.4.2.2 Frame-Sync Generator

The transmit frame-sync pin is `abe_mcasp_afsx`. The frame-sync generator must be configured through the control register (`MCASP_TXFMCTL`) as:

- Internally generated `MCASP_TXFMCTL[1]` FSXM = 1
- Frame-sync polarity: Rising edge `MCASP_TXFMCTL[0]` FSXP = 0
- Frame-sync width: Single bit `MCASP_TXFMCTL[4]` FXWID = 0
- 384-slot, `MCASP_TXFMCTL[15:7]` XMOD = 1 1000 0000b

### 23.8.4.3 Serializers

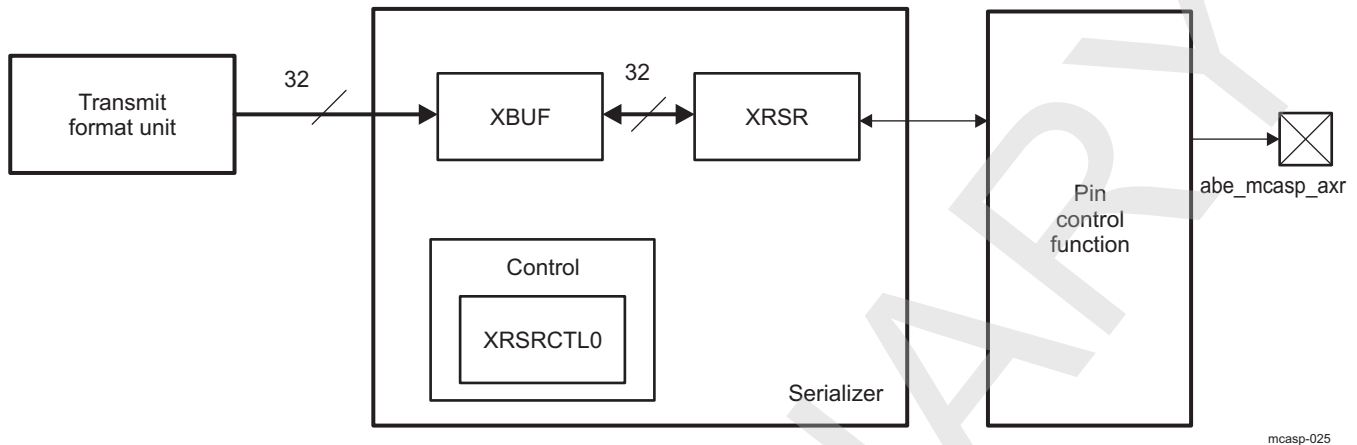

The serializer shifts serial data out of the McASP. It consists of a shift register (XRSR), a data buffer (XBUF), a control register (`MCASP_XRSRCTL0`), a serial data pin (`abe_mcasp_axr`), and logic to support the data alignment options of the McASP.

The serializer must be configured to transmit through the control register, thus shifting out data to `abe_mcasp_axr`. The serializer is clocked from the transmit section clock (`abe_mcasp_aclkx`) if configured to transmit. A serializer configured to transmit operates in lockstep.

Figure 23-195 is the serializer block diagram.

**Figure 23-195. Individual Serializer and Connections Within McASP**

For transmit, the microprocessor unit (MPU) services the McASP by writing data into the XBUF register, which is an alias of the [MCASP\\_TXBUF0](#) register. The data automatically passes through the transmit format unit before reaching the XBUF register in the serializer. The data is then copied from XBUF to XRSR and shifted out from `abe_mcasp_axr` synchronously to the serial clock.

In addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.). The serializer configuration is controlled by [MCASP\\_XRSRCTL0\[1:0\]](#) SRMOD = 0x1. Thus, the serializer is configured to operate in transmit mode.

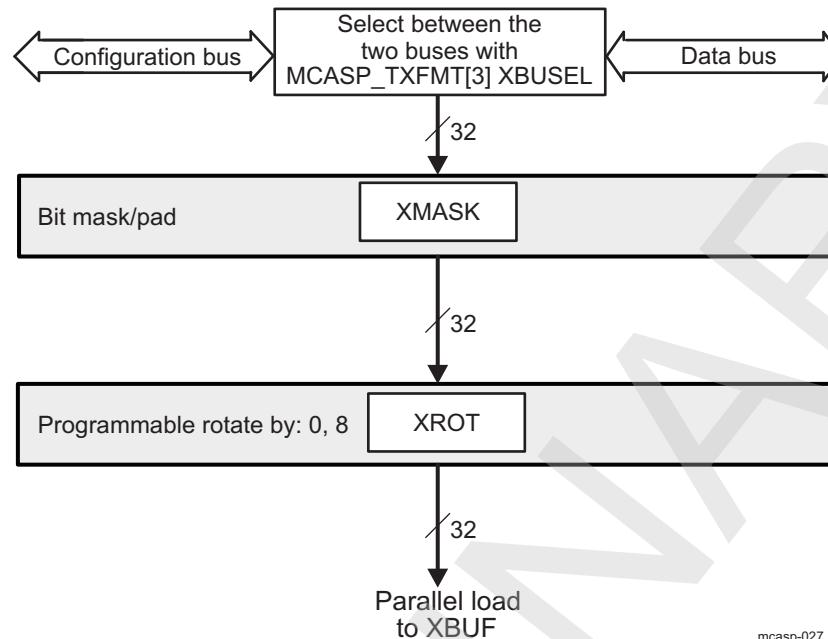

#### 23.8.4.4 Format Unit

The McASP has one transmit data formatting unit. This unit automatically remaps the data bits within the transmitted words between a natural format for the MPU (such as a Q31 representation) and the required format for the external serial device. During the remapping process, the format unit can also mask off certain bits.

This formatting unit consists of two stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)

Figure 23-196 shows the transmit formatting unit.

**Figure 23-196. Transmit Format Unit**

As shown in [Figure 23-196](#), the data to the transmit format unit can come from the configuration bus or the data bus. The selection is made through the [MCASP\\_TXFMT\[3\] XBUSEL](#) bit.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

The rotate-right stage performs bitwise rotation by 0 bits for right-aligned Q31 data and bitwise rotation by 8 bits for left-aligned Q31 data, programmable by the [MCASP\\_TXFMT\[2:0\] XROT](#) bit field. This is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the process.

The [MCASP\\_TXFMT\[17:16\] XDATLY](#) bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned 24-bit audio data, ready for transmission:

- [MCASP\\_TXFMT\[2:0\] XROT](#) = 0x2 (rotate right by 8 bits)
- [MCASP\\_TXFMT\[15\] XRVRS](#) = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in an LSB-first order.
- [MCASP\\_TXMASK\[32\] XMASK](#) = 0xFFFFFFFF00 – 0xFFFF0000
- [MCASP\\_TXFMT\[14:13\] XPAD](#) = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned 24-bit audio data ready for transmission:

- [MCASP\\_TXFMT\[2:0\] XROT](#) = 0x0 (rotate right by 0 bits)
- [MCASP\\_TXFMT\[15\] XRVRS](#) = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in an LSB-first order.
- [MCASP\\_TXMASK\[32\] XMASK](#) = 0x00FFFFFF – 0x0000FFFF
- [MCASP\\_TXFMT\[14:13\] XPAD](#) = 0x0 (Pad extra bits with 0s.)

[Table 23-589](#) provides more details and specific examples. The examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

#### 23.8.4.5 Transmit State-Machine

The transmit state-machine controls the interactions between the various units in the transmit section. In addition, the state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the transmit state-machine is released from reset.

The transmit state-machine is controlled by the transmit bit stream format register ([MCASP\\_TXFMT](#)) and it reports the McASP status and error conditions in the transmitter status register ([MCASP\\_TXSTAT](#)).

#### 23.8.4.6 Transmit TDM Sequencer

The time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to the [MCASP\\_TXBUF0](#) register during the current time slot (slot 1) is actually shifted out on the next time slot.

The transmit TDM sequencer is controlled by the [MCASP\\_TXTDM](#) register and reports the current transmit slot to the [MCASP\\_TXTDMSLOT\[9:0\]](#) XSLOT CNT bit field.

#### 23.8.4.7 McASP Software Reset

The McASP can be put into reset through the global transmit control register ([MCASP\\_GBLCTL](#)). A valid serial clock must be supplied to the McASP to assert the software reset bits in the [MCASP\\_GBLCTL](#) register.

#### 23.8.4.8 McASP Power Management

[Table 23-569](#) describes power-management features available to the McASP.

**Table 23-569. Local Power-Management Features**

Feature	Registers	Description
Slave idle modes	<a href="#">MCASP_SYSCONFIG[1:0]</a> IDLE_MODE	Force-idle, no-idle, and smart-idle modes are available.

#### 23.8.4.9 Transfer Modes

##### 23.8.4.9.1 DIT Transfer Mode

The DIT transfer mode of the McASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode applies only to a serializer configured as transmitter, not receiver. For a description of the S/PDIF format, see [Section 23.8.2.2.3, S/PDIF Coding Format](#).

##### 23.8.4.9.1.1 Transmit DIT Encoding

When the McASP operates in DIT mode, the data transmitted is output as a biphase-mark encoded bit stream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bit stream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

The transmit TDM time slot register ([MCASP\\_TXTDM](#)) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in DIT mode, the following pins are typically required:

- `abe_mcaspl_ahclkx` – transmit high-frequency master clock (The internal clock source can be used instead.)
- One serial data pin, `abe_mcaspl_axr`, with serializer configured to transmit

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

##### 23.8.4.9.1.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register ([MCASP\\_TXFMCTL](#)):

- Internally generated transmit frame sync, FSXM = 1
- Rising-edge frame sync, FSXP = 0
- Bit-width frame sync, FXWID = 0
- 384-slot TDM, XMOD = 1 1000 0000b
- In the transmit clock control register ([MCASP\\_ACLKXCTL](#)), ASYNC = 1
- In the transmit bit stream format register ([MCASP\\_TXFMT](#)), XSSZ = 1111 (32-bit slot size)

All combinations of `abe_mcasp_ahclkx` and `abe_mcasp_aclkx` are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

- [MCASP\\_PFUNC](#): The data pin must be configured for McASP function. If `abe_mcasp_ahclkx` is used, it must also be configured for McASP function. Other pins can be configured to function as GPIOs, if desired.
- [MCASP\\_PDIR](#): The data pin must be configured as output. If internal clock source AUXCLK is used as the reference clock, it may be output on the `abe_mcasp_ahclkx` pin by configuring `abe_mcasp_ahclkx` as an output.
- [MCASP\\_GBLCTL](#): Global initialization
- [MCASP\\_AMUTE](#): Program all fields according to the mute control desired.
- [MCASP\\_TXDITCTL](#): The **DITEN** bit must be set to 1 to enable DIT mode. Configure other bits as desired.
- [MCASP\\_TXMASK](#): Mask the desired bits, depending upon left-aligned or right-aligned internal data.
- [MCASP\\_TXFMT](#): **XDATDLY** = 0. **XRVR** = 0. **XPAD** = 0. **XSSZ** = Fh (32-bit slot). **XBUSEL** = configured as desired. The **XROT** bit is configured either 0 or 8-bit rotate.
- [MCASP\\_TXFMCTL](#): Configure the bits according to former discussions.
- [MCASP\\_ACLKXCTL](#): **ASYNC** = 1. Program the CLKXDIV bits to obtain the bit clock rate desired. CLKXM = 1.
- [MCASP\\_AHCLKXCTL](#): Program the HCLKXDIV bits to obtain the high-frequency bit clock rate desired.
- [MCASP\\_TXTDM](#): Set to FFFF FFFFh for all active slots for DIT transfers.
- [MCASP\\_TXEVTCTL](#): Program all fields according to the interrupts desired.
- [MCASP\\_TXCLKCHK](#): Program all fields according to the clock checking desired.
- [MCASP\\_XRSRCTL0](#): Set **SRMOD** = 1 (transmitter) for the DIT pins.
- [MCASP\\_DITCSRAi](#) and [MCASP\\_DITCSRBi](#): Program the channel status bits as desired.
- [MCASP\\_DITUDRAi](#) and [MCASP\\_DITUDRBi](#): Program the user data bits as desired.

#### 23.8.4.9.1.3 DIT Channel Status and User Data Register Files

The channel status registers ([MCASP\\_DITCSRAi](#) and [MCASP\\_DITCSRBi](#)) and user data registers ([MCASP\\_DITUDRAi](#) and [MCASP\\_DITUDRBi](#)) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the MPU reads the transmit TDM slot counter to determine which word of the register is being used.

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bit stream.

The DIT subframe format is defined in [Section 23.8.2.2.3.2, Subframe Format](#). The channel status information (C) and user data (U) are defined in the following DIT control registers:

- [MCASP\\_DITCSRA0](#) to [MCASP\\_DITCSRA5](#): The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- [MCASP\\_DITCSRB0](#) to [MCASP\\_DITCSRB5](#): The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- [MCASP\\_DITUDRA0](#) to [MCASP\\_DITUDRA5](#): The 192 bits in these six registers contain the user data information for the left channel within each frame.

- MCASP\_DITUDRB0 to MCASP\_DITUDRB5: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in [Figure 23-191](#). There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in [Table 23-570](#).

**Table 23-570. Channel Status and User Data for Each DIT Block**

### 23.8.4.10 Data Transmission

The MPU services the McASP by writing data to the [MCASP\\_TXBUF0](#) register for transmit operations. The McASP sets status flags and notifies the MPU whenever data is ready to be transmitted. [Section 23.8.4.10.1](#), *Data Ready Status and Event/Interrupt Generation*, discusses data-ready status in detail.

The [MCASP\\_TXBUF0](#) register can be accessed through one of the two peripheral ports of the device:

- Data port (DAT): This port is dedicated to data transfers on the device.
- Configuration bus (CFG): This port is used for data transfers and peripheral configuration control on the device.

[Section 23.8.4.10.1.2](#), *Transfers Through the Data Port (DAT)*, and [Section 23.8.4.10.1.3](#), *Transfers Through the Configuration Bus (CFG)*, discuss how to perform transfers through the data port and the configuration bus, respectively.

The MPU or the DMA can be used to service the McASP through either of these peripheral ports. The MPU and DMA usages are discussed in [Section 23.8.4.10.1.4](#), *Using the MPU for McASP Servicing*, and [Section 23.8.4.10.1.5](#), *Using the DMA for McASP Servicing*, respectively.

#### 23.8.4.10.1 Data Ready Status and Event/Interrupt Generation

##### 23.8.4.10.1.1 Transmit Data Ready

The transmit data ready flag XDATA bit in the [MCASP\\_TXSTAT](#) register reflects the status of the [MCASP\\_TXBUF0](#) register. The XDATA flag is set when data is transferred from the [MCASP\\_TXBUF0\[n\]](#) buffer to the XRSR[n] shift register, thus indicating that the [MCASP\\_TXBUF0](#) is empty and ready to accept new data from the MPU. This flag is cleared when the XDATA bit is written with 1, or when the serializer configured as transmitter is written by the MPU.

Whenever XDATA is set, the DMA AXEVT event is automatically generated to notify the DMA of the [MCASP\\_TXBUF0](#) empty status. An AXINTn interrupt is also generated if the XDATA interrupt is enabled in the [MCASP\\_EVTCTLX](#) register (for details, see [Section 23.8.4.11.1](#), *Transmit Data Ready Interrupt*).

For DMA requests, the McASP does not require that [MCASP\\_TXSTAT](#) be read between DMA events. This means that, even if [MCASP\\_TXSTAT](#) already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

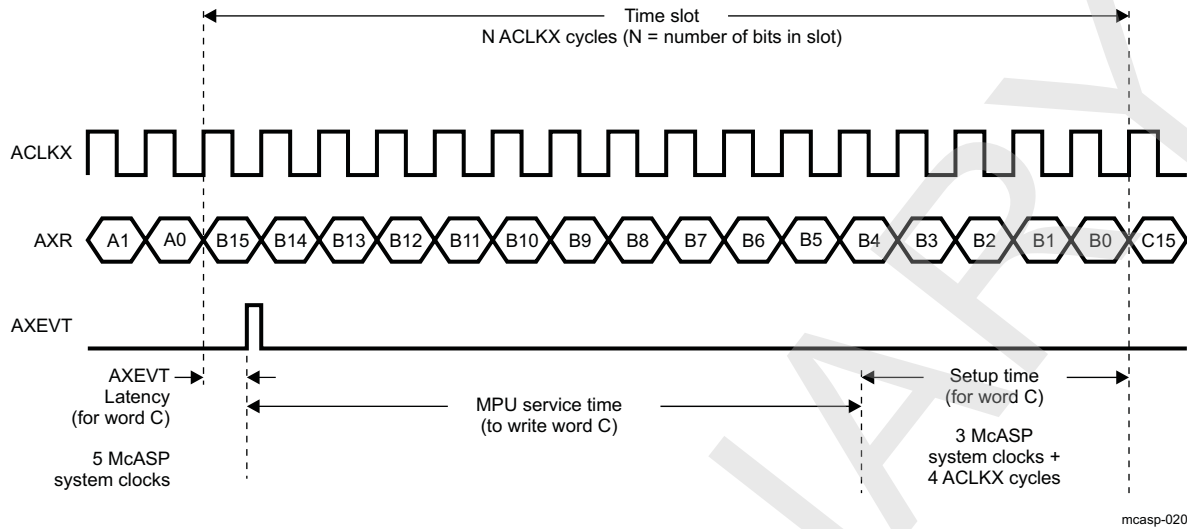

Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

[Figure 23-197](#) shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to five McASP system clocks (AXEVT latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the MPU can begin servicing the McASP by writing word C into the [MCASP\\_TXBUF0](#) (service time). The MPU must write word C into the [MCASP\\_TXBUF0](#) within the setup time required by the McASP (setup time).

The maximum service time (see [Figure 23-197](#)) can be calculated as:

$$\text{Service Time} = \text{Time Slot} - \text{AXEVT Latency} - \text{Setup Time}$$

Figure 23-197. MPU Service Time Upon Transmit DMA Event (AXEVT)

23.8.4.10.1.2 Transfers Through the Data Port (DAT)

**CAUTION**

To perform internal transfers through the data port, clear the XBUSEL bit to 0 in the [MCASP\\_TXFMT](#) register. Failure to do so may result in software malfunction.

Typically, the [MCASP\\_TXBUF0](#) register is accessed through the data port. To access through the data port, simply have the MPU or DMA access [MCASP\\_TXBUF0](#) through its data port location.

**NOTE:** DAT allows the MPU, DSP subsystem, or DMA to access only the transmit buffer [MCASP\\_TXBUF0](#) register. There is no way to access the McASP configuration registers within the MPU/DSP subsystem/DMA DAT address ranges.

For transmit operations through the data port, the DMA/MPU must write to the [MCASP\\_TXBUF0](#) data port address to service the active transmit serializer.

When transmitting, the DMA/MPU must write data to the serializer and transmit within each time slot. Failure to do so may result in a buffer underrun condition (see [Section 23.8.4.14.1, Buffer Underrun Error – Transmitter](#)).

23.8.4.10.1.3 Transfers Through the Configuration Bus (CFG)

**CAUTION**

To perform internal transfers through the configuration bus, set the XBUSEL bit to 1 in the [MCASP\\_TXFMT](#) register. Failure to do so may result in software malfunction.

In this method, the DMA/MPU accesses the [MCASP\\_TXBUF0](#) register through the configuration bus address.

When transmitting, the DMA/MPU must write data to the serializer and transmit within each time slot. Failure to do so may result in a buffer underrun condition ([Section 23.8.4.14.1, Buffer Underrun Error – Transmitter](#)).

#### 23.8.4.10.1.4 Using the MPU for McASP Servicing

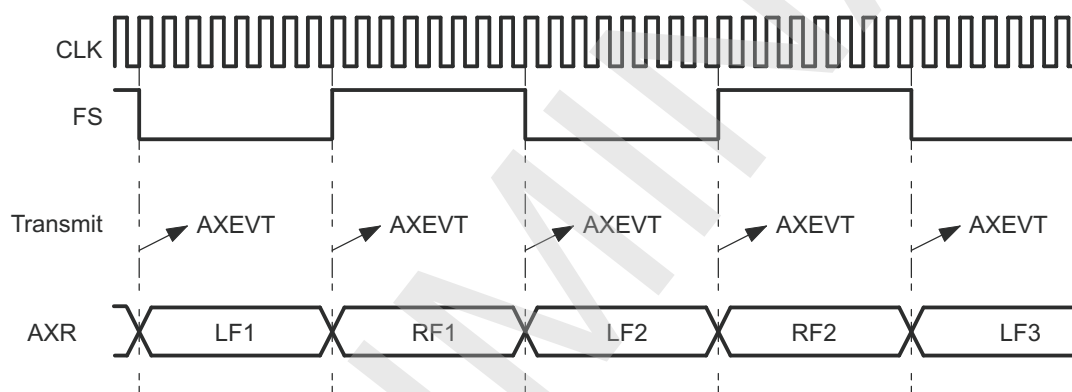

The MPU can be used to service the McASP through interrupts (upon MCASP\_AXINT interrupt) or through polling the XDATA bit in the [MCASP\\_TXSTAT](#) register. As discussed in [Section 23.8.4.10.1.2, Transfers Through the Data Port \(DAT\)](#), and [Section 23.8.4.10.1.3, Transfers Through the Configuration Bus \(CFG\)](#), the MPU can access through the data port or the configuration bus.

To use the MPU to service the McASP through interrupts, the XSTAT bit must be enabled in the [MCASP\\_TXEVTCTL](#) register to generate the MCASP\_AXINT interrupt to the MPU upon data ready.

#### 23.8.4.10.1.5 Using the DMA for McASP Servicing

The typical scenario is to use the DMA to service the McASP through the data port, although the DMA can also service the McASP through the configuration bus.

**Figure 23-198. DMA Transmit Event in an Audio Example – One Event**

mcasep-013

The DMA event AXEVT, which is triggered upon each XDATA transition from 0 to 1, is used to service the McASP transmit buffer (XBUF). [Figure 23-198](#) is an example of an audio system with two audio channels (LF and RF) transmitted through the `abe_mcasp_axr` pin on the McASP. It shows the points at which event AXEVT is triggered.

The DMA AXEVT event is triggered on each time slot. In the example, AXEVT is triggered for each transmit audio channel time slot (time slot for channel LF, and time slot for channel RF). DMA events are generated automatically upon data ready, whereas MPU interrupt generation must be enabled in the [MCASP\\_EVTCTLX](#) register.

#### 23.8.4.11 Interrupt Requests

[Table 23-571](#) lists the event flags that can cause module interrupts.

**Table 23-571. TX Events**

Event Mask	Event Flag	Map to	Description
<a href="#">MCASP_EVTCTLX[0]</a> XUNDRN	<a href="#">MCASP_TXSTAT[0]</a> XUNDRN	MCASP_AXINT	Transmit underrun
<a href="#">MCASP_EVTCTLX[1]</a> XSYNCERR	<a href="#">MCASP_TXSTAT[1]</a> XSYNCERR	MCASP_AXINT	Unexpected transmit frame sync
<a href="#">MCASP_EVTCTLX[2]</a> XCKFAIL	<a href="#">MCASP_TXSTAT[2]</a> XCKFAIL	MCASP_AXINT	Transmit clock failure
<a href="#">MCASP_EVTCTLX[4]</a> XLAST	<a href="#">MCASP_TXSTAT[4]</a> XLAST	MCASP_AXINT	Transmit last slot interrupt
<a href="#">MCASP_EVTCTLX[5]</a> XDATA	<a href="#">MCASP_TXSTAT[5]</a> XDATA	MCASP_AXINT	Transmit data-ready interrupt
<a href="#">MCASP_EVTCTLX[7]</a> XSTAFRM	<a href="#">MCASP_TXSTAT[7]</a> XSTAFRM	MCASP_AXINT	Transmit start of frame interrupt

An interrupt line is asserted (active high) when one of these events occurs. Read the [MCASP\\_TXSTAT](#) register to determine which event occurs.

#### **23.8.4.11.1 Transmit Data Ready Interrupt**

The transmit data-ready interrupt (XDATA) is generated if XDATA is 1 in the [MCASP\\_TXSTAT](#) register and XDATA is enabled in [MCASP\\_EVTCTLX](#). [Section 23.8.4.10.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when XDATA is set in the [MCASP\\_TXSTAT](#) register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior as the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

#### **23.8.4.11.2 Error Interrupt**

Upon detection, the following error conditions generate interrupt flags:

In the transmit status register ([MCASP\\_TXSTAT](#)):

- Transmit underrun (XUNDRN)
- Transmit DMA error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register ([MCASP\\_EVTCTLX](#)). If the enable bit is set, an interrupt is requested when the interrupt flag is set in [MCASP\\_TXSTAT](#). If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

#### **23.8.4.12 DMA Requests**

The McASP can generate one DMA request to the sDMA and eDMA controllers to transmit data ([MCASP\\_AXEVT](#)).

A DMA request to transmit data is generated if the XDATDMA bit in the [MCASP\\_TXEVTCTL](#) register is cleared.

#### **23.8.4.13 Audio Mute (AMUTE) Function**

The McASP includes an automatic audio mute function (see [Figure 23-199](#)) that asserts, in hardware, the AMUTE pin to a preprogrammed output state, as selected by the MUTEN bit in the audio mute control register ([MCASP\\_AMUTE](#)). The AMUTE pin is asserted when one of the interrupt flags is set or an external device issues an error signal on the `abe_mcasp_amutein` input. Typically, the `abe_mcasp_amutein` input is shared with a device interrupt pin.

The `abe_mcasp_amutein` input allows the on-chip logic to consider a mute input from other devices in the system so that all errors may be considered. The `abe_mcasp_amutein` input has a programmable polarity to allow it to adapt to different devices, as selected by the INPOL bit in the [MCASP\\_AMUTE](#) register, and it must be explicitly enabled.

In addition to the external `abe_mcasp_amutein` input, the `abe_mcasp_amute` pin output may be asserted when one of the error interrupt flags is set and its mute function is enabled in the [MCASP\\_AMUTE](#) register.

When one or more errors are detected and enabled, the `abe_mcasp_amute` pin is driven to an active state that is selected by MUTEN in the [MCASP\\_AMUTE](#) register. The active polarity of the AMUTE pin is programmable by the MUTEN bit (the inactive polarity is the opposite of the active polarity). The `abe_mcasp_amute` pin remains driven active until software clears all the error interrupt flags that are enabled to mute, and until the `abe_mcasp_amutein` is inactive.

**Figure 23-199. Audio Mute (AMUTE) Block Diagram**

#### 23.8.4.14 Error Reporting

The McASP includes error-checking capability for the serial protocol and data underrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

When one or more errors (software selectable) are detected or the `abe_mccasp_amutein` input pin is asserted, the `abe_mccasp_amute` output pin may be asserted to a high or low level to immediately mute the audio output. In addition, an interrupt can be generated if desired, based on one or more error sources.

#### **23.8.4.14.1 Buffer Underrun Error –Transmitter**

A buffer underrun occurs when the serializer is instructed by the transmit state-machine to transfer data from `MCASP_TXBUF0` to XRSR, but `MCASP_TXBUF0` has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The `MCASP_TXSTAT[0]` XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it.

A pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bps). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the McASP and restart with the proper initialization.

#### **23.8.4.14.2 DMA Error –Transmitter**

A transmit DMA error, as indicated by the XDMAERR flag in the `MCASP_TXSTAT` register, occurs when the DMA (or MPU) writes more words to the data port of the McASP than it should.

XDMAERR indicates that the DMA (or MPU) wrote too many words to the McASP for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in `MCASP_TXSTAT`.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or MPU. The McASP transmitter and the DMA must be reinitialized to resynchronize them.

#### **23.8.4.14.3 Clock Failure Detection**

##### **23.8.4.14.3.1 Clock Failure Check Startup**

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

To start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (`MCASP_TXCLKCHK`).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register (`MCASP_TXSTAT`).
3. Wait until the first measurement is taken (> 32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
  - (a) The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (`MCASP_EVTCTLX`)
  - (b) The mute option (XCKFAIL) in the mute control register (`MCASP_AMUTE`)

##### **23.8.4.14.3.2 Transmit Clock Failure Check and Recovery**

The transmit clock failure check circuit (see [Figure 23-200](#)) works off the internal McASP system clock and the external high-frequency serial clock (`abe_mcasp_ahclkx`). It continually counts the number of system clocks for every 32 high-rate serial clock (`abe_mcasp_ahclkx`) periods, and stores the count in XCNT of the transmit clock check control register (`MCASP_TXCLKCHK`) every 32 high-rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in `MCASP_TXSTAT`) when an out-of-range condition occurs. An

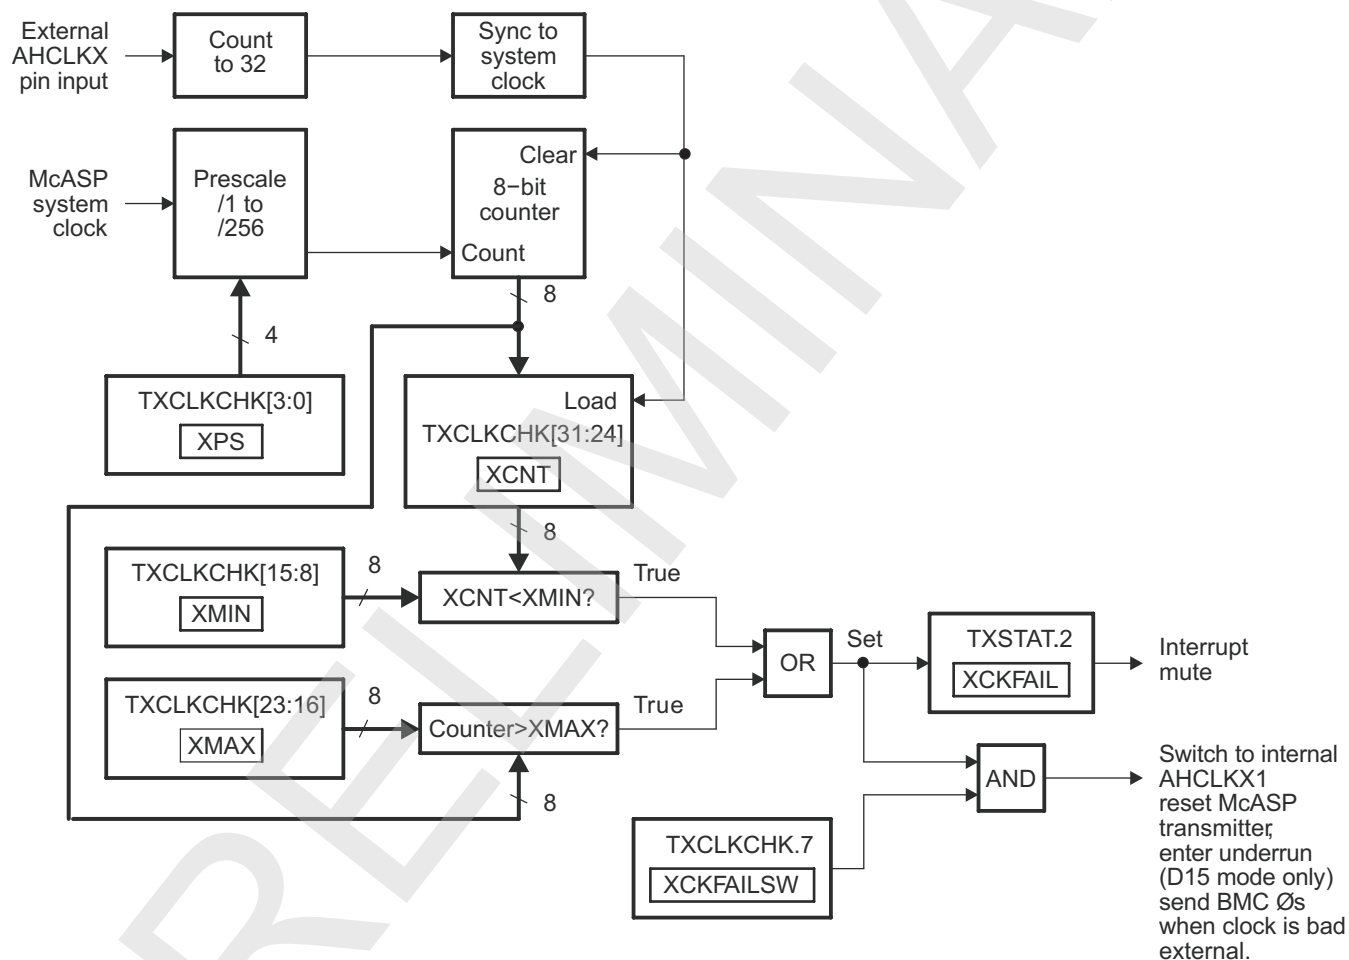

out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running system clock counter) to the maximum allowable boundary (XMAX). This is so that if the external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the transmit clock failure flag (XCKFAIL) in `MCASP_TXSTAT` is set. This causes an interrupt if the transmit clock failure interrupt enable bit (XCKFAIL) in `MCASP_EVTCTLX` is set.

**Figure 23-200. Transmit Clock Failure Detection Circuit Block Diagram**

mcasep-014

## 23.8.5 McASP Low-Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the McASP module.

### 23.8.5.1 Global Initialization

#### 23.8.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the McASP module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the McASP (for more information, see the [Section 23.8.3](#), *McASP Integration*, and [Section 23.8.2](#), *McASP Environment*).

[Table 23-572](#), describes the global initialization of surrounding modules.

**Table 23-572. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled. (See <a href="#">Chapter 3</a> , <i>Power, Reset, and Clock Management</i> .)
Control module	Module-specific pad muxing and other pad configurations must be set in the control module. (See <a href="#">Chapter 18</a> , <i>Control Module</i> .)
(Optional) Cortex-A9 MPU INTC or DSP INTC	INTC configuration must be done to enable the interrupts from the McASP. (See <a href="#">Chapter 17</a> , <i>Interrupt Controllers</i> .)
(Optional) sDMA (or eDMA or ADMA)	DMA configuration must be done to enable the McASP DMA data channel requests.
(Optional) ABE_L4 and L3 Interconnects	For more information about the interconnect configuration, see <a href="#">Chapter 13</a> , <i>Interconnect</i> .

**NOTE:** The MPU/DSP INTC and the sDMA/eDMA/ADMA configurations are required when the interrupt and DMA-based communication modes are used.

#### 23.8.5.1.2 McASP Global Initialization

##### 23.8.5.1.2.1 Main Sequence – McASP Global Initialization

The procedure in [Table 23-573](#) initializes the McASP after a power-on reset (POR).

**Table 23-573. McASP Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Apply software reset to different McASP components.	<a href="#">MCASP_GBLCTL</a> [12:8]	0x00
Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	<a href="#">MCASP_GBLCTL</a> [12:8]	=0x00
Configure the local power management.	<a href="#">MCASP_SYSCONFIG</a> [1:0] IDLE_MODE	0x-
Configure the transmit format unit.	See <a href="#">Section 23.8.5.1.2.2</a> .	
Configure the transmit frame sync generator.	See <a href="#">Section 23.8.5.1.2.3</a> .	
Configure the transmit clock generator.	See <a href="#">Section 23.8.5.1.2.4</a> .	
Configure the TDM sequencer—set all slots active.	<a href="#">MCASP_TXTDM</a> [31:0] XTDMs	0xFFFF FFFF
Configure the serializer for transmit mode operation.	<a href="#">MCASP_XRSRCTL0</a> [1:0] SRMOD	0x1
Configure the McASP pins functionality.	See <a href="#">Section 23.8.5.1.2.5</a> .	
Configure the McASP mute input/output conditions.	See <a href="#">Table 23-578</a> .	
Enable the McASP DIT-transmission mode.	<a href="#">MCASP_TXDITCTL</a> [0] DITEN	0x1
Configure DIT-specific subframe fields.	See <a href="#">Table 23-579</a> .	

**Table 23-573. McASP Global Initialization (continued)**

Step	Register/Bit Field/Programming Model	Value
Release from reset state the divider that outputs the <code>abe_mcasp_ahclkx</code> clock. <sup>(1)</sup>	<code>MCASP_GBLCTL[9]</code> XHCLKRST	0x1
Poll the bit to ensure that it is successfully latched in the register.	<code>MCASP_GBLCTL[9]</code> XHCLKRST	=0x1
Release from reset state the divider that outputs the <code>abe_mcasp_aclkx</code> clock. <sup>(1)</sup>	<code>MCASP_GBLCTL[8]</code> XCLKRST	0x1
Poll the bit to ensure that it is successfully latched in the register.	<code>MCASP_GBLCTL[8]</code> XCLKRST	=0x1

<sup>(1)</sup> During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the `MCASP_AHCLKX` and `MCASP_ACLKX` registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.

### 23.8.5.1.2.2 Subsequence – Transmit Format Unit Configuration

The procedure in [Table 23-574](#) configures the transmit frame format unit of the McASP module.

**NOTE:**

- The first transmit data bit always has a 0-bit delay.
- The bit stream is always transmitted in least-significant-bit (LSB)-first order.
- Pad value for extra bits in a certain slot is always 0.

**Table 23-574. Transmit Format Unit Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure the slot size to 32 bits.	<code>MCASP_TXFMT[7:4]</code> XSSZ	0xF
<b>IF:</b> the MPU or DMA data to transmit is left- aligned	Software test condition	
Set data mask in the range 0xFFFF FF00 – 0xFFFF 0000.	<code>MCASP_TXMASK[31:0]</code> XMASK	0x-
Rotate data right by 8-bit positions.	<code>MCASP_TXFMT[2:0]</code> XROT	0x2
<b>ELSE</b>		
Set data mask in the range 0x00FF FFFF– 0x0000 FFFF.	<code>MCASP_TXMASK[31:0]</code> XMASK	0x-
Rotate data right by 0-bit positions.	<code>MCASP_TXFMT[2:0]</code> XROT	0x0
<b>ENDIF</b>		

### 23.8.5.1.2.3 Subsequence – Transmit Frame Synchronization Generator Configuration

The procedure in [Table 23-575](#) configures the transmit frame synchronization generator of the McASP module.

**NOTE:** The frame synchronization signal is always rising-edge active and always has a single-bit width.

**Table 23-575. Transmit Frame-Synchronization Generator Configuration**

Step	Register/Bit Field/Programming Model	Value
Select 384-slot size block.	<code>MCASP_TXFMCTL[15:7]</code> XMOD	0x180
Select internally-generated transmit frame sync.	<code>MCASP_TXFMCTL[1]</code> FSXM	0x1

### 23.8.5.1.2.4 Subsequence – Transmit Clock Generator Configuration

**NOTE:** By default, the ACLKX and AHCLKX clocks are generated only from the McASP internal clock source.

The procedure in [Table 23-576](#) configures the transmit clock generator of the McASP module.

**Table 23-576. Transmit Clock Generator Configuration**

Step	Register/Bit Field/Programming Model	Value
Set the divisor for the internally generated high frequency clock– <code>abe_mcasp_ahclkx</code> .	<code>MCASP_AHCLKXCTL[11:0]</code> HCLKXDIV	0x-
Set the divisor for the internally generated transmission clock– <code>abe_mcasp_aclkx</code> .	<code>MCASP_ACLKXCTL[4:0]</code> CLKXDIV	0x-
Configure the transmit clock failure detect logic.	See <a href="#">Section 23.8.4.14.3.1</a> , <i>Clock Failure Check Startup</i> .	

### 23.8.5.1.2.5 Subsequence—McASP Pins Functional Configuration

The procedure in [Table 23-577](#) configures the McASP pins for McASP functionality.

**Table 23-577. McASP Pins Functional Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	<code>MCASP_PFUNC[31:0]</code>	0x0
Configure the McASP pins as outputs:	<code>MCASP_PDIR[28]</code> AFSX;	0x1
<code>abe_mcasp_afsx</code>	<code>MCASP_PDIR[27]</code> AHCLKX;	0x1
<code>abe_mcasp_ahclkx</code>	<code>MCASP_PDIR[26]</code> ACLKX;	0x1
<code>abe_mcasp_aclkx</code>	<code>MCASP_PDIR[25]</code> AMUTE;	0x1
<code>abe_mcasp_amute</code>	<code>MCASP_PDIR[0]</code> AXR0;	0x1
<code>abe_mcasp_axr</code>		

### 23.8.5.1.2.6 Subsequence – McASP Mute Input/Output Trigger Condition Settings

The procedure in [Table 23-578](#) configures the behavior of the mute associated I/Os and different trigger conditions for the McASP mute output functionality.

**Table 23-578. McASP Mute Input/Output Trigger Condition Settings**

Step	Register/Bit Field/Programming Model	Value
Optional: Select to drive AMUTE active enable bit on transmit DMA error.	<code>MCASP_AMUTE[12]</code> XDMAERR	0x1
Optional: Select to drive AMUTE active enable bit on transmit clock failure.	<code>MCASP_AMUTE[10]</code> XCKFAIL	0x1
Optional: Select to drive AMUTE active enable bit on transmit frame synchronization error.	<code>MCASP_AMUTE[8]</code> XSYNCERR	0x1
Optional: Select to drive AMUTE active enable bit on transmit underrun error.	<code>MCASP_AMUTE[6]</code> XUNDRN	0x1
Optional: Enable sensitivity of the <code>abe_mcasp_amute</code> output to <code>abe_mcasp_amutein</code> error source.	<code>MCASP_AMUTE[3]</code> INEN	0x1
Optional: Select the <code>abe_mcasp_amutein</code> input polarity.	<code>MCASP_AMUTE[2]</code> INPOL	0x1
Optional: Configure the behavior of the <code>abe_mcasp_amute</code> output.	<code>MCASP_AMUTE[1:0]</code> MUTEN	0x1

### 23.8.5.1.2.7 Subsequence – DIT-Specific Subframe Fields Configuration

**NOTE:** The McASP integrated in the device supports only the DIT transmission mode that uses the S/PDIF protocol.

The procedure in [Table 23-579](#) configures the DIT-specific subframe fields as part of the S/PDIF format data.

**Table 23-579. DIT-Specific Subframe Fields Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure the valid bit value for odd time slots.	MCASP_TXDITCTL[3] VB	0x-
Configure the valid bit value for even time slots.	MCASP_TXDITCTL[2] VA	0x-
Configure the user data bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITUDRAi[31:0] DITUDRAi, where i = 0 to 5	0x-
	MCASP_DITUDRBi[31:0] DITUDRBi, where i = 0 to 5	0x-
Configure the channel status bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITCSRAi[31:0], where i = 0 to 5	0x-
	MCASP_DITCSRBi[31:0], where i = 0 to 5	0x-

## 23.8.5.2 Operational Modes Configuration

### 23.8.5.2.1 McASP DIT Transmission Mode

#### 23.8.5.2.1.1 Main Sequence – McASP DIT Polling Transmission Method

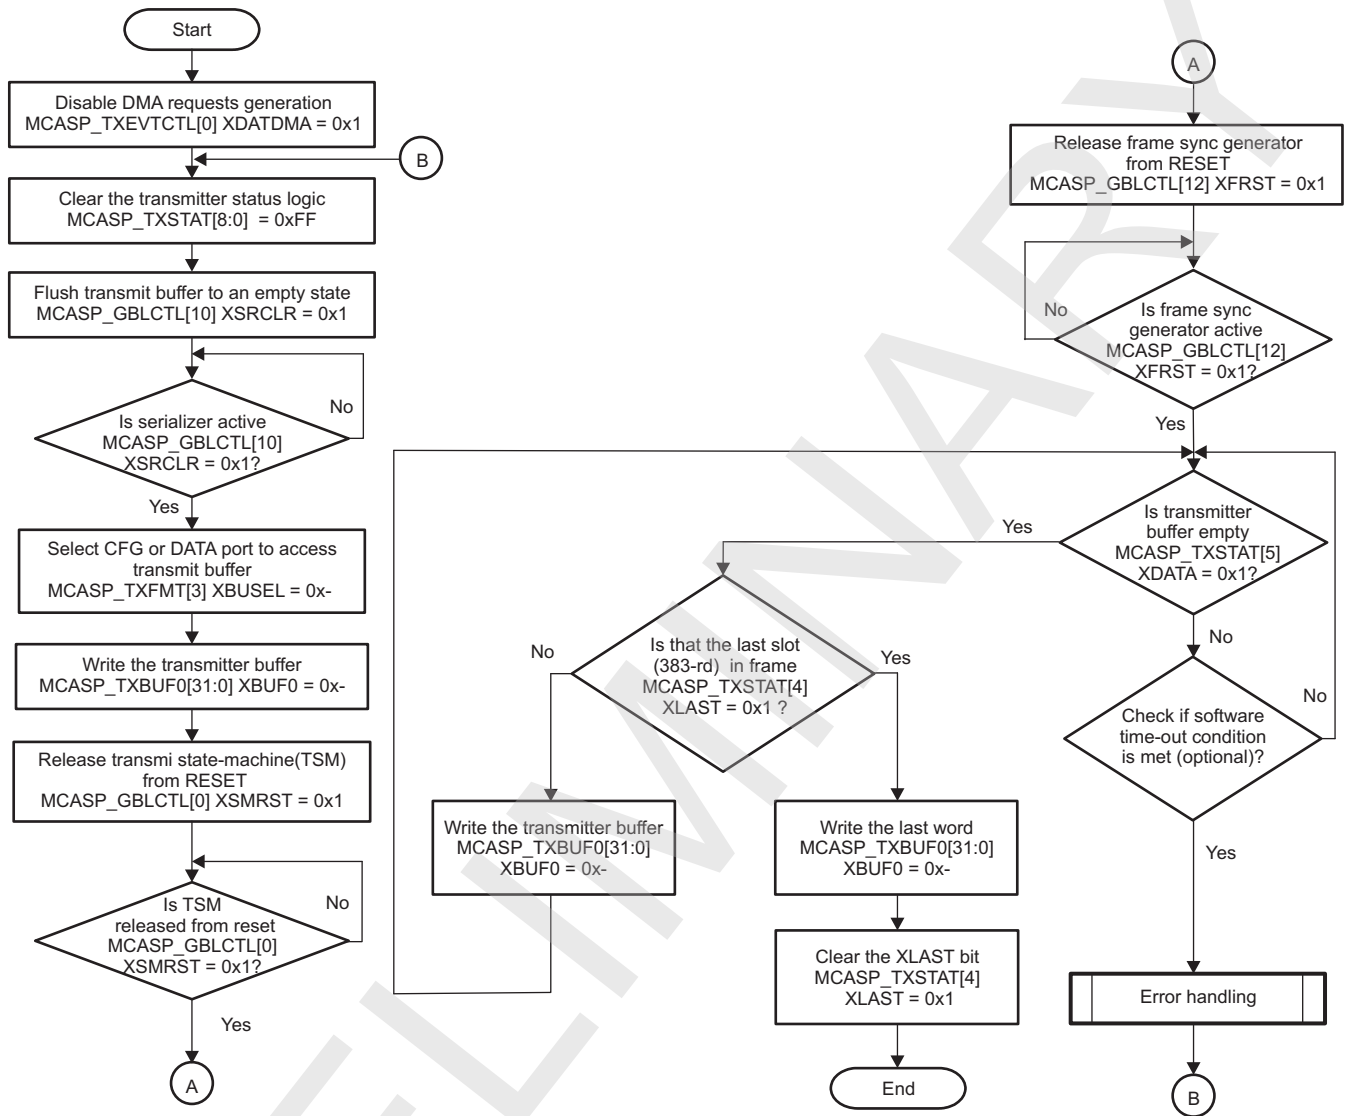

[Figure 23-201](#) shows the McASP DIT polling method.

**NOTE:**

- The McASP polling transmission model considers the MPU/DSP as the source of audio data for the McASP transmission buffer.
- The DMA request is disabled and the XDMAERR event is not analyzed.
- The flow chart shown in [Figure 23-201](#) shows the sequence for transmitting one DIT frame.

Figure 23-201. McASP DIT Transmission Polling Method

mcasp-028

Table 23-580 summarizes the register call for the polling mode.

Table 23-580. Register Call Summary for Main Sequence – McASP DIT Transmission Polling Method

Register Name	Register Name	Register Name	Register Name	Register Name
MCASP_TXSTAT	MCASP_GBLCTL	MCASP_TXBUF0	MCASP_TXFMT	MCASP_TXEVTCTL

Table 23-581 summarizes the subprocess call for the polling mode.

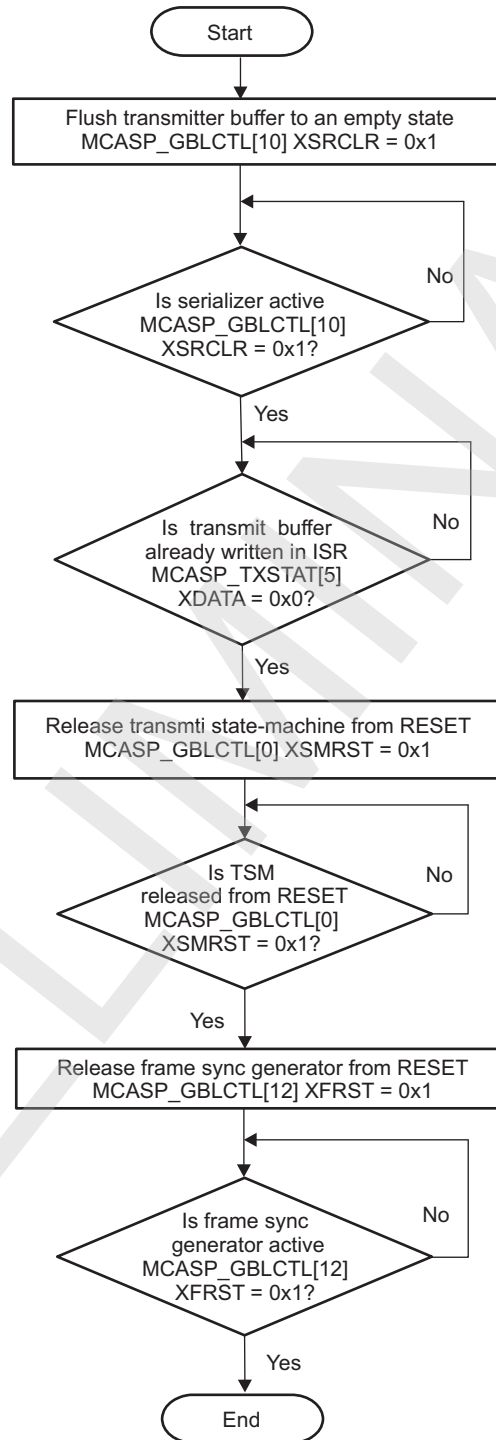

Table 23-581. Subprocess Call Summary for Main Sequence – McASP DIT Transmission Polling Method

Subprocess Name	Cross-Reference
Error handling	Figure 23-205

### 23.8.5.2.1.2 Main Sequence – McASP DIT Interrupt Transmission Method

Figure 23-202 shows the initial setup for interrupt-based transmission.

**Figure 23-202. Subsequence – DIT Transmission Startup Procedure**

mcaspp-029

Table 23-582 shows the configuration of the McASP using the McASP DIT interrupt method for transmission.

**Table 23-582. McASP Interrupt Transmission Model**

Step	Register/Bit Field/Programming Model	Value
Select the CFG or DATA port to access the transmit buffer.	MCASP_TXFMT[3] XBUSEL	0x-
Disable DMA requests generation.	MCASP_TXEVTCTL[0] XDATDMA	0x1
Clear the transmitter status logic.	MCASP_TXSTAT[8:0]	0xFF
Enable the data ready event transmit interrupt.	MCASP_EVTCTLX[5] XDATA	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
Disable the DMA error event.	MCASP_EVTCTLX[7] XDMAERR	0x0
DIT transmission startup procedure	See <a href="#">Figure 23-202</a> .	

[Table 23-583](#) summarizes the register call to initialize the McASP to transmit using interrupt events.

**Table 23-583. Register Call Summary for Subsequence – McASP DIT Transmission Startup Procedure**

Register Name	Register Name
MCASP_GBLCTL	MCASP_TXBUF0

**23.8.5.2.1.3 Main Sequence –McASP DIT DMA Transmission Method**

[Table 23-584](#) shows the configuration of the McASP using the DMA method for transmission. Possible interrupt error event servicing is also considered. [Table 23-583](#) shows the initial setup for DMA-based transmission.

**NOTE:** Because of the DATA port burst access capability with the DMA method, It is preferable for transfers to be initiated through the DATA port rather than through the CFG port.

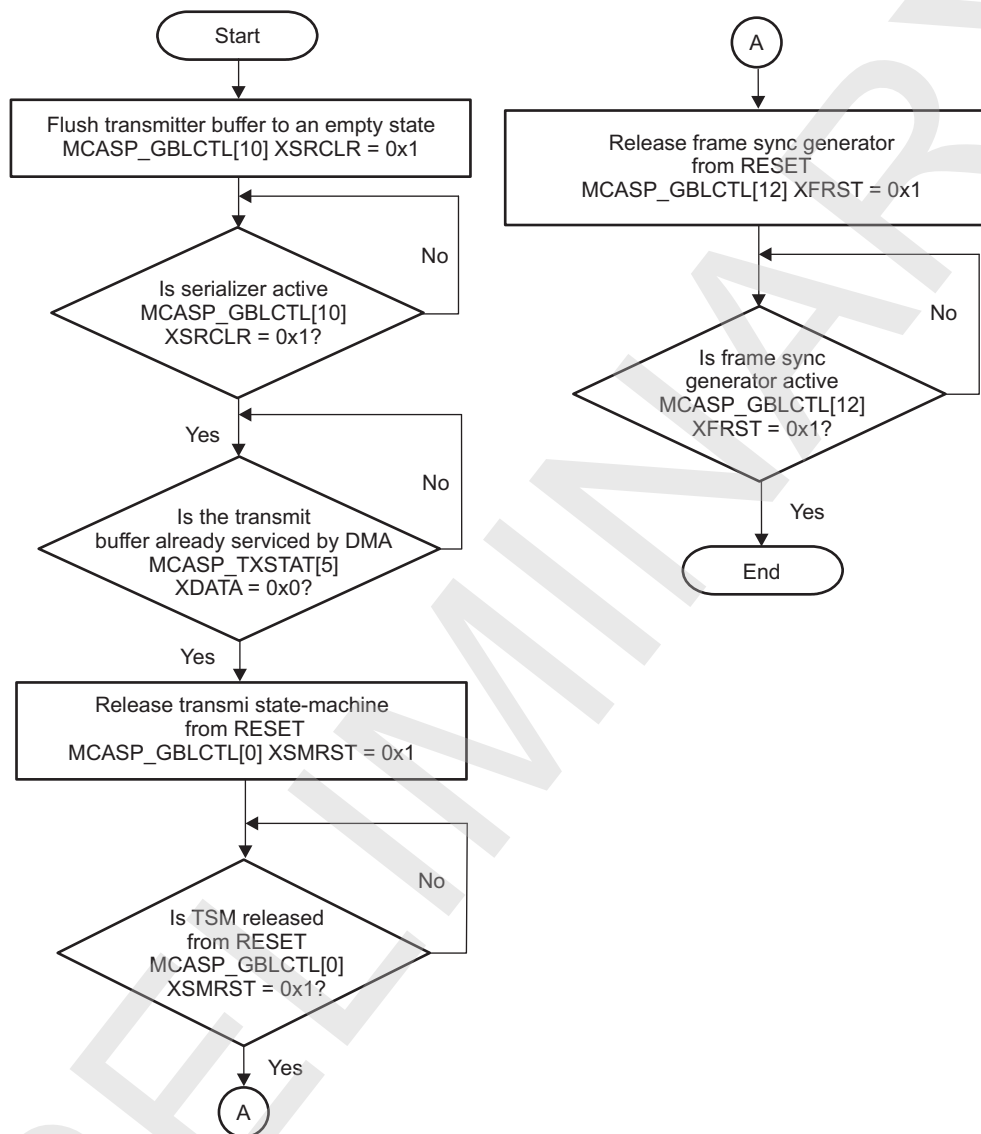

**Table 23-584. McASP DMA Transmission Model with Interrupt Events Servicing**

Step	Register/Bit Field/Programming Model	Value
Select DATA port to access the transmit buffer.	MCASP_TXFMT[3] XBUSEL	0x0
Enable the DMA requests generation.	MCASP_TXEVTCTL[0] XDATDMA	0x0
Clear the transmitter status logic.	MCASP_TXSTAT[8:0]	0xFF
Enable the DMA error event.	MCASP_EVTCTLX[7] XDMAERR	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
Disable the data ready event transmit interrupt.	MCASP_EVTCTLX[5] XDATA	0x0
DMA transmission procedure	See <a href="#">Section 23.8.5.2.1.4</a> .	

### 23.8.5.2.1.4 Subsequence – DIT DMA Transmission Procedure

Figure 23-203 shows the McASP initial setup when the DMA method is used for transmission.

**Figure 23-203. Subsequence – DIT DMA Transmission Procedure**

mcasep-030

Table 23-585 shows the register call summary for the McASP DMA transmission procedure subsequence.

**Table 23-585. Register Call Summary for Subsequence – McASP DMA Transmission Procedure**

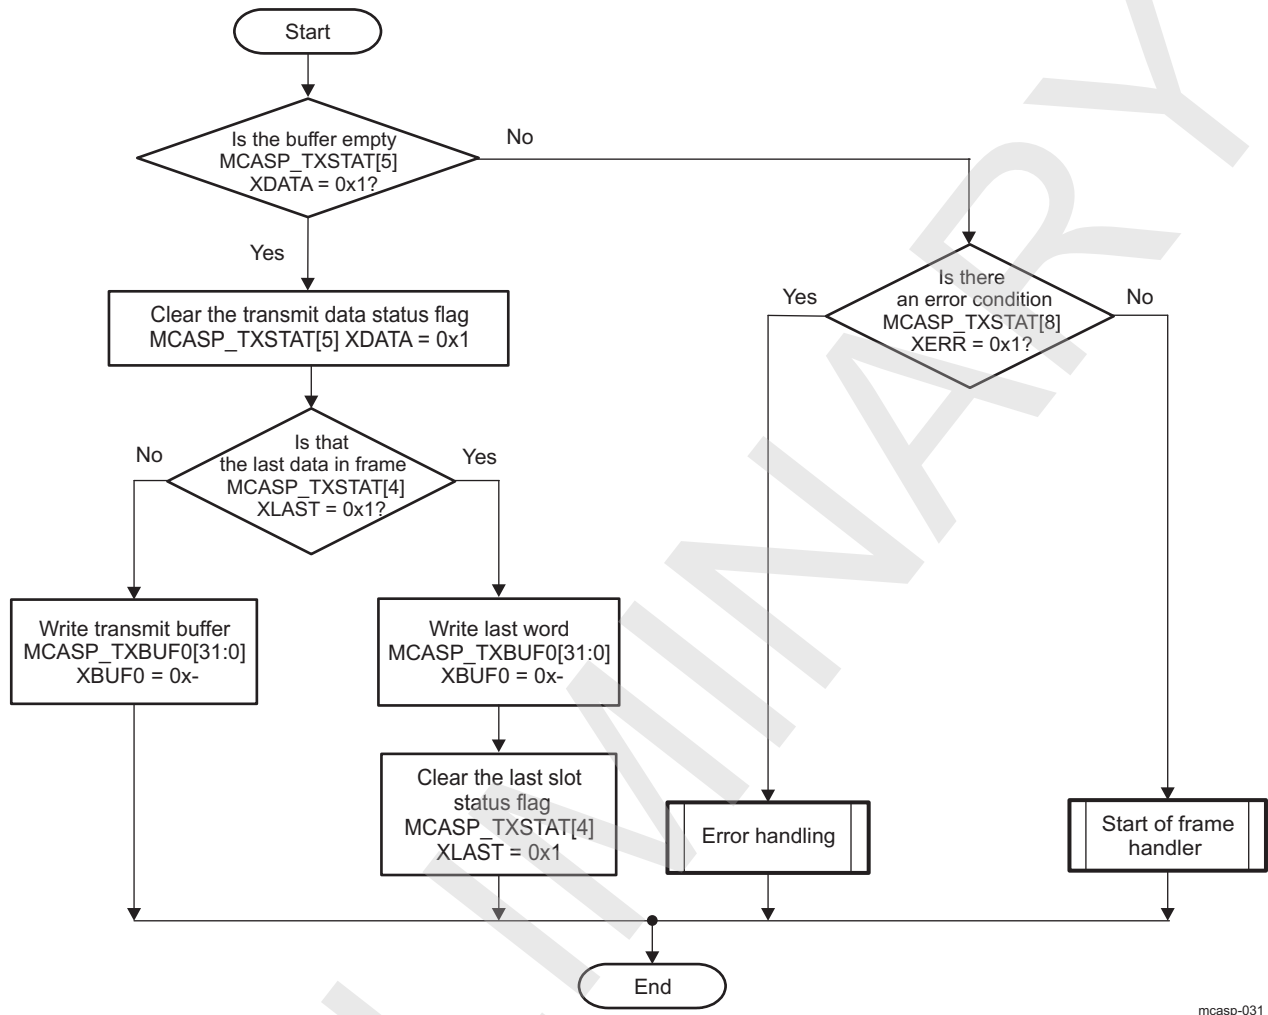

Register Name	Register Name
MCASP_TXSTAT	MCASP_GBLCTL

### 23.8.5.2.2 McASP Event Servicing

#### 23.8.5.2.2.1 McASP Interrupt Events Servicing

Figure 23-204 shows the flow of interrupt events servicing for the McASP module.

Figure 23-204. McASP Interrupt Events Servicing

mcasp-031

Table 23-586 lists the register call summary for the interrupt event servicing.

Table 23-586. Register Call Summary for McASP Interrupt Events Servicing

Register Name	Register Name
MCASP_TXSTAT	MCASP_TXBUF0

Table 23-587 lists the subprocess call summary for interrupt events servicing.

Table 23-587. Subprocess Call Summary for Interrupt Events Servicing

Subprocess Name	Cross-Reference
Error handling	Figure 23-205
Start of frame handling	Section 23.8.4.11.1

### 23.8.5.2.2.2 Subsequence – Error Handling

Figure 23-205 shows the error handling schema for the McASP, which can be implemented as part of the interrupt service routine or as part of polling sequence.

**Figure 23-205. McASP Error Handling**

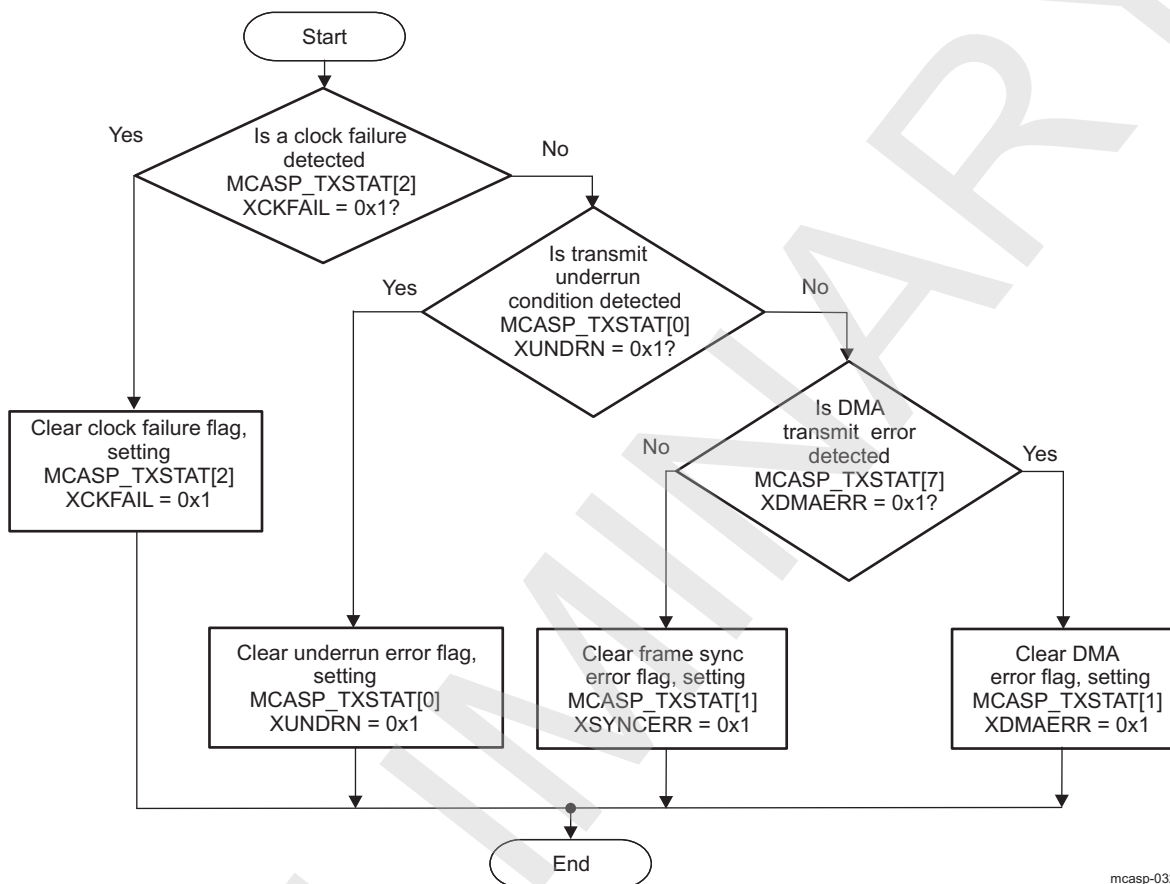

Table 23-588 lists the register call summary for the McASP error handling.

**Table 23-588. Register Call Summary for McASP Error Handling**

Register Name
MCASP_TXSTAT

**NOTE:**

- For more information about clock failure handling, see [Section 23.8.4.14.3](#).
- For more information about transmit buffer underrun handling, see [Section 23.8.4.14.1](#).
- For more information about DMA error handling, see [Section 23.8.4.14.2](#).

## 23.8.6 McASP Register Manual

### 23.8.6.1 McASP Instance Summary

Table 23-589 summarizes the McASP instances.

**Table 23-589. McASP Instance Summary**

Module Name	Base Address L3 Interconnect	Base Address Cortex-A9 Private Access	Base Address DSP Private Access	Size
McASP	0x4902 8000	0x4012 8000	0x01D2 8000	4KB

**NOTE:** Private access is an access that does not use the L3 / L4 interconnects.

### 23.8.6.2 McASP Registers

#### 23.8.6.2.1 McASP Register Summary

Table 23-590 summarizes the McASP register mapping.

**Table 23-590. McASP Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address L3 Interconnect	Physical Address Cortex-A9 Private Access	Physical Address DSP Private Access

**Table 23-607. MCASP\_GBLCTL**

<b>Address Offset</b>	0x0000 0044	<b>Instance</b>	McASP
<b>Physical Address</b>	See <a href="#">Table 23-590</a> .		
<b>Description</b>	Global transmit control register - provides initialization of the transmit section. The bit fields in <a href="#">MCASP_GBLCTL</a> are synchronized and latched by the <code>abe_mcasp_aclkx</code> clock. Before programming <a href="#">MCASP_GBLCTL</a> , ensure that the serial clocks are running. If the corresponding external serial clock, <code>abe_mcasp_clkx</code> , is not yet running, select the internal serial clock source in <code>AHCLKXCTL</code> and <code>ACLKXCTL</code> before programming <a href="#">MCASP_GBLCTL</a> . Also, after programming any bits in <a href="#">MCASP_GBLCTL</a> , do not proceed until reading back from <a href="#">MCASP_GBLCTL</a> and verifying that the bits in <a href="#">MCASP_GBLCTL</a> are latched.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																XFRST	XSMRST	XSRCLR	XHCLKRST	XCLKRST	RESERVED										

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Reserved	RW	0x00000
12	XFRST	Transmit frame-sync generator reset enable bit 0x0: The transmit frame-sync generator is reset. 0x1: The transmit frame-sync generator is active. When released from reset, the transmit frame-sync generator begins counting serial clocks and generating frame sync as programmed.	RW	0

Bits	Field Name	Description	Type	Reset
11	XSMRST	<p>Transmit state-machine reset enable bit</p> <p>0x0: The transmit state-machine is held in reset.</p> <p>abe_mcasp_axr pin state: If <a href="#">MCASP_PFUNC</a>[0] = 0 and <a href="#">MCASP_PDIR</a>[0] = 1, the serializer drives the abe_mcasp_axr pin to the state specified for inactive time slot</p> <p>0x1: The transmit state-machine is released from reset. When released from reset, the transmit state-machine immediately transfers data from XBUF[n] to XRSR[n]. The transmit state-machine sets the underrun flag (XUNDRN) in MCASP_XSTAT, if XBUF[n] have not been preloaded with data before reset is released. The transmit state-machine also immediately begins detecting frame sync and is ready to transmit. Transmission of TDM time slot begins at slot 0 after reset is released.</p>	RW	0
10	XSRCLR	<p>Transmit serializer clear enable bit. By clearing and then setting this bit, the transmit buffer is flushed to an empty state (XDATA = 1). If XSMRST = 1, XSRCLR = 1, XDATA = 1, and XBUF is not loaded with new data before the start of the next active time slot, an underrun occurs.</p> <p>0x0: The transmit serializer is cleared.</p> <p>0x1: The transmit serializer is active. When the transmit serializer is first taken out of reset (XSRCLR changes from 0 to 1), the transmit data ready bit (XDATA) in MCASP_XSTAT is set to indicate XBUF is ready to be written.</p>	RW	0

**Table 23-627. MCASP\_TXSTAT**

<b>Address Offset</b>	0x0000 00C0	<b>Instance</b>	McASP
<b>Physical Address</b>	See <a href="#">Table 23-590</a> .		
<b>Description</b>	Transmitter status register - If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes the generation of a new interrupt request.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																XERR	XDMAERR	XSTAFRM	XDATA	XLAST	XTDMSLOT	XCKFAIL	XSYNCERR	XUNDRN							

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	RW	0x000000
8	XERR	XERR bit always returns a logic-OR of: XUNDRN   XSYNCERR   XCKFAIL   XDMAERR. Allows a single bit to be checked to determine if a transmitter error interrupt has occurred.  0x0: No errors have occurred. 0x1: An error has occurred.	RW	0
7	XDMAERR	Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more words to the data port of the McASPin a given time slot than it should. Causes a transmit interrupt (XINT) if this bit and XDMAERR in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.  0x0: Transmit DMA error did not occur. 0x1: Transmit DMA error occurred.	RW	0
6	XSTAFRM	Transmit start of frame flag. Causes a transmit interrupt (XINT) if this bit and XSTAFRM in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.  0x0: No new transmit frame sync (AFSX) is detected. 0x1: A new transmit frame sync (AFSX) is detected.	RW	0
5	XDATA	Transmit data ready flag. Causes a transmit interrupt (XINT) if this bit and XDATA in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect  0x0: XBUF is written and is full  0x1: Data is copied from XBUF to XRSR. XBUF is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT).	RW	0
4	XLAST	Transmit last slot flag. XLAST, along with XDATA, are set if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT) if this bit and XLAST in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.  0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. XDATA is also set.	RW	0

Bits	Field Name	Description	Type	Reset
3	XTDMSLOT	Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd. read 0x0: Current TDM time slot is odd. read 0x1: Current TDM time slot is even.	R	0
2	XCKFAIL	Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error. Causes a transmit interrupt (XINT) if this bit and XCKFAIL in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmit clock failure did not occur. 0x1: Transmit clock failure occurred	RW	0
1	XSYNCERR	Unexpected transmit frame-sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT) if this bit and XSYNCERR in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Unexpected transmit frame sync did not occur 0x1: Unexpected transmit frame sync occurred.	RW	0
0	XUNDRN	Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF to XRSR, but XBUF has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT) if this bit and XUNDRN in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmitter underrun did not occur 0x1: Transmitter underrun occurred.	RW	0

### 23.9 Serial Low-Power Inter-Chip Media Bus Controller

This section describes the features and functions of the serial low-power inter-chip media bus (SLIMbus®) controller.

#### 23.9.1 SLIMbus Overview

There are two SLIMbus module instantiations, SLIMBUS1 and SLIMBUS2, in the device. SLIMbus1 is implemented in the audio backend (ABE) subsystem and is intended for the connection of external audio peripherals. SLIMBUS2 is at the top-level of the device and is intended for the connection of other types of peripherals.

The SLIMbus controller provides a bidirectional, multidrop, multichannel two-line serial interface between the device and other SLIMbus components in a system, such as audio codecs, Bluetooth® modules, and FM radio receivers/transmitters. Because of its versatility, the SLIMbus controller can play the role of a wide range of peripherals and clocked frame-oriented protocols ( I2S™, PCM, and TDM).

Figure 23-206 shows the SLIMbus1 controller highlight.

Figure 23-206. SLIMbus1 Highlight

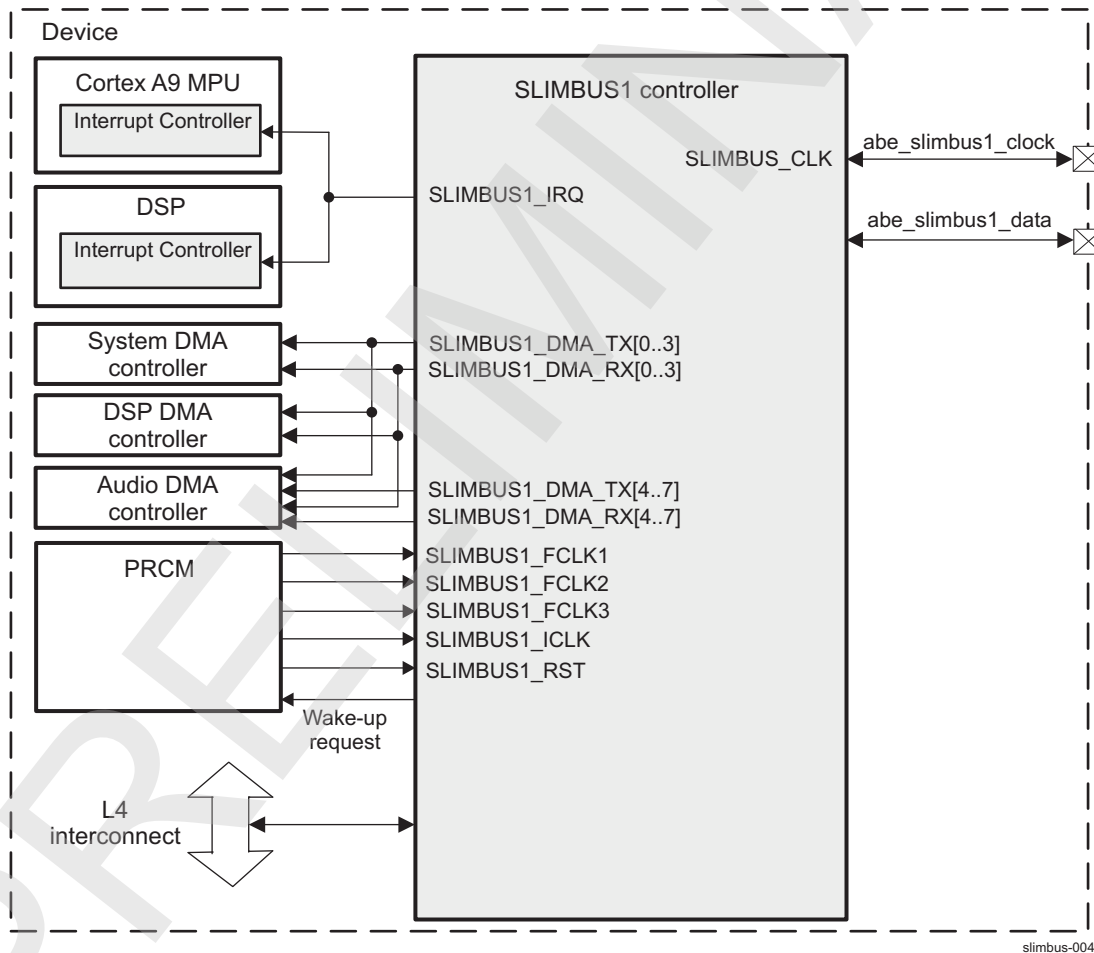

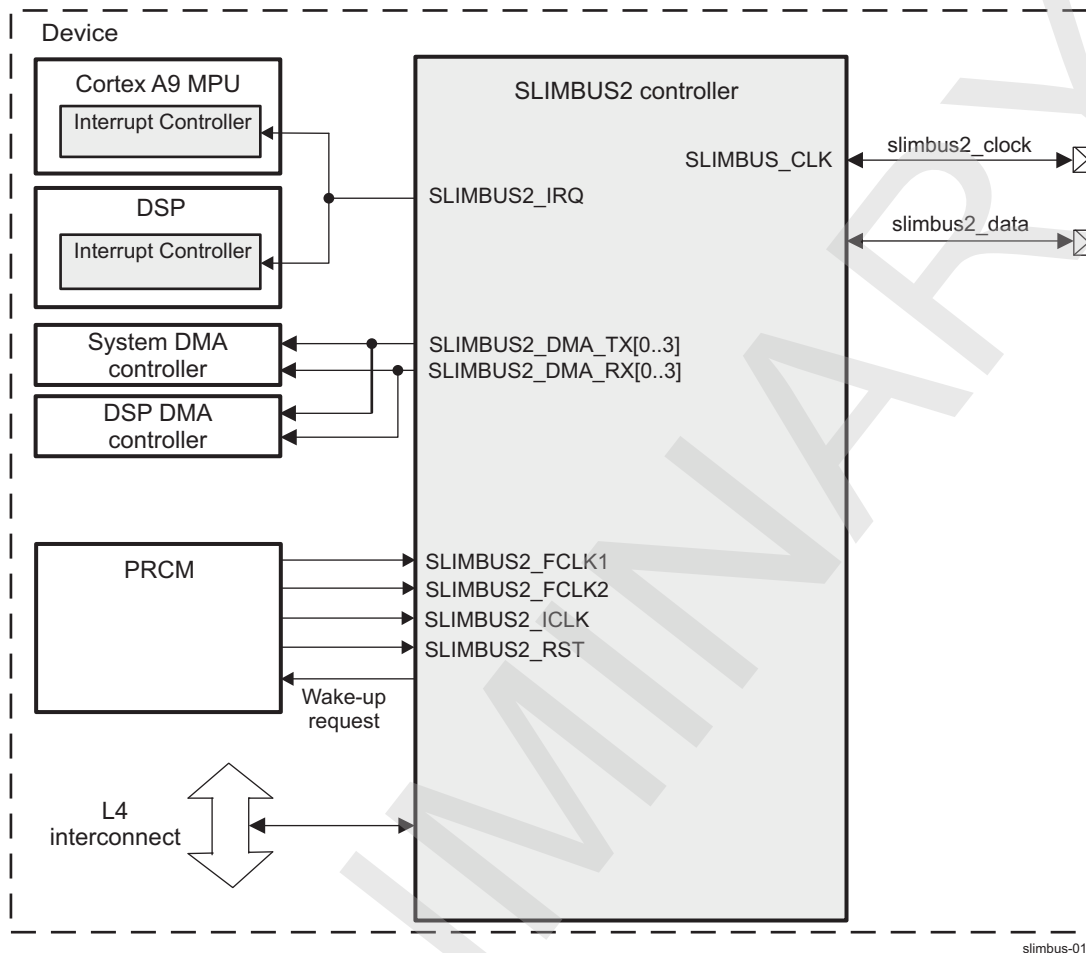

Figure 23-207 shows the SLIMbus2 controller highlight.

**Figure 23-207. SLIMbus2 Highlight**

### 23.9.1.1 Terminology

The SLIMbus module is by default the SLIMbus controller IP. The module implements a SLIMbus component by integrating together several submodules: a SLIMbus component contains a set of devices and the necessary logic needed to provide bus access to these devices.

Every component contains one Interface device and can contain additional devices belonging to other device classes (framer, manager, or generic devices).

- An interface device is the central status and control location of the component. All components have only one interface device.
- A framer device can generate the clock and synchronization information for the entire SLIMbus. Consequently, only one framer device (for all SLIMbus components) at a time can be active on the bus.
- A manager device controls the bus scheduling at high level: It assigns logical addresses to any device that is authorized to communicate using the bus, gives the bandwidth allocation, and so on. Only one manager device at a time can be active on the bus.
- A generic device implements the "useful" functionality of the component by sourcing/sinking the payload data. A component may include several generic devices so that each appears as a separate, standardized entity to the software driver.

**NOTE:** Typically, generic devices are used to transport data (rather than the specialized manager, framer, or interface devices, which typically do not feature data ports).

A device is a separately addressable entity within a SLIMbus component. Each device belongs to a single device class. After enumeration each device is addressed with a single logical address. A device (and especially a generic device) contains data ports to transmit and/or receive data. Each port is identified within the device by its port number (PN). A port is identified within the SLIMbus by its device address (logical address or enumeration address) and PN.

An enumeration address (EA) is a 48-bit value (composed of the manufacturer ID, product code, device ID, and instance value) that allows a device to receive messages.

A logical address (LA) is an 8-bit number used to uniquely identify an enumerated device on the bus.

### 23.9.1.2 Main Features

Each SLIMbus module includes the following main features:

- SLIMbus controller compliant with the MIPI SLIMbus standard version 1.01.00
- Support of seven SLIMbus devices:
  - One Interface device
  - One framer device
  - One manager device
  - Four generic devices
- SLIMBUS1: Eight TX and eight RX independent ports (data channels)
- SLIMBUS2: Four TX and four RX independent ports (data channels)
- FIFO access (one FIFO for transmit and one for receive), with DMA request (one line for transmit port and one line for receive port)
- SLIMBUS1: Message FIFO size is 32 bytes for transmit and 32 bytes for receive.
- SLIMBUS2: Message FIFO size is 32 bytes for transmit and 32 bytes for receive, by default. The message FIFO size can be reprogrammed to 64 (or 16 or 48) bytes if needed. However, typical use never exceeds 32 bytes.
- Data channel FIFO size is programmable for both modules.
- Programmable data length (sample size) from 4 to 32 bits
- Programmable port assignment to either of the four generic devices
- Supported transport protocols: Isochronous, pulled, pushed, asynchronous, and extended asynchronous transport protocols (the latter two in simplex and one-half duplex mode)
- No support for locked protocol
- SLIMbus clock rate: From 0 to 24.576 MHz

Each SLIMbus module has the following characteristics:

- The component is implemented by a digital controller (the current module), plus a physical layer (a set of CLK + DATA bidirectional input/output [I/O] drivers).
- Devices are logical entities implemented by a combination of hardware (automatic address decoding for message reception) and software (message decode, encode, etc.).
- Ports (and their mapping to data channels) are supported by the module hardware-implemented data channel agents. Each agent features a unidirectional FIFO, a DMA request, support for a number of transfer protocols, etc. One agent is used per port and per data direction: Transfer protocols are unidirectional and require only one data channel agent per data channel.

## 23.9.2 SLIMbus Environment

### 23.9.2.1 SLIMbus Component Connection Example

Figure 23-208 shows an example of a system with the SLIMbus1 controller connected to an audio peripheral component.

**Figure 23-208. SLIMbus1 Typical Application System Overview**

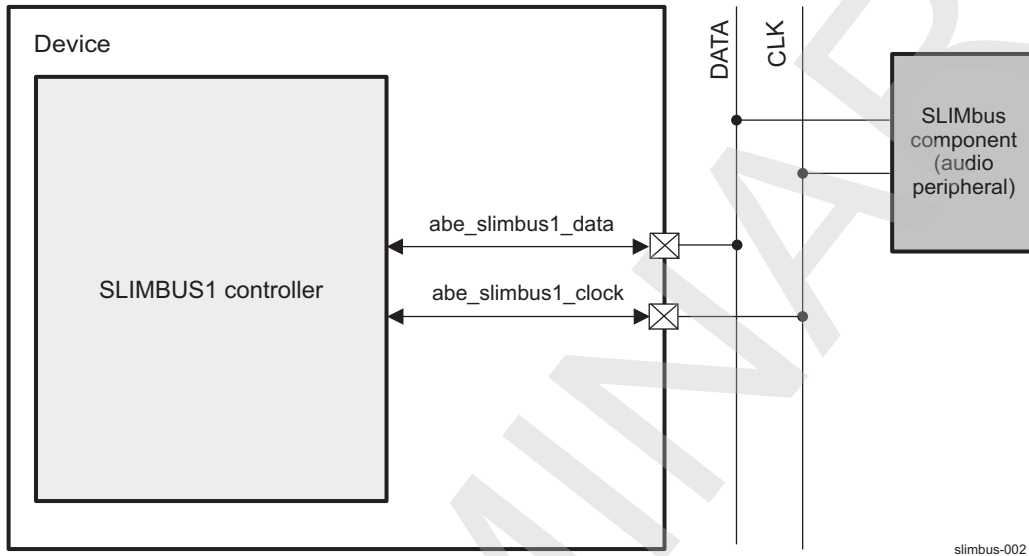

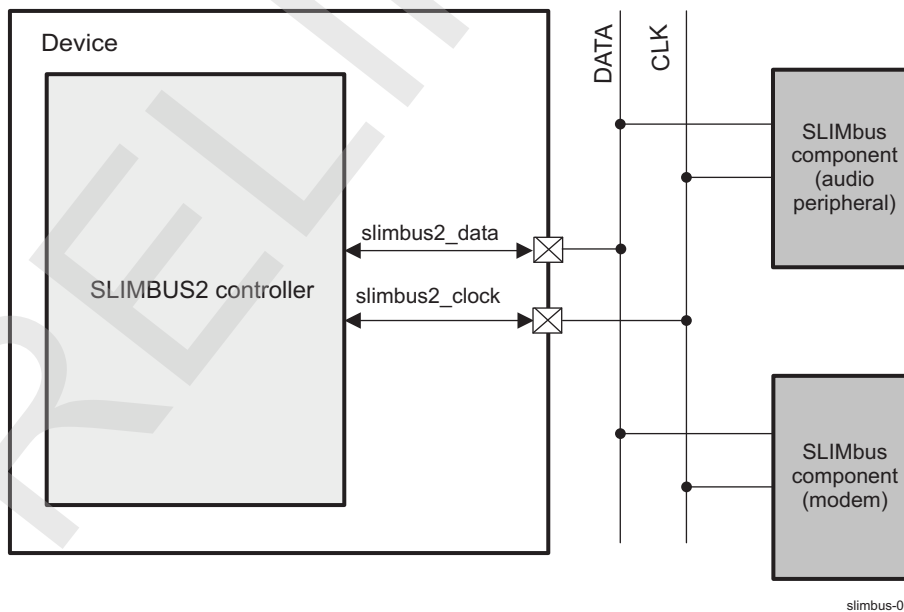

Figure 23-209 shows an example of a system with the SLIMbus2 controller connected to one audio peripheral component and one modem component.

**Figure 23-209. SLIMbus2 Typical Application System Overview**

The physical medium of SLIMbus is composed of two lines: CLK and DATA. All components of the bus are attached to both lines. The clock line (CLK) is driven by the (component containing the) active framer, and received (and used) by all other components on the bus. The data line (DATA) is driven alternately by all components, following the SLIMbus protocol.

The SLIMbus uses non-return-to-zero inverted (NRZI) signalling:

- A logical 1 is represented by a transition (a change) in the physical level.
- A logical 0 is represented by the same physical level as the previous bit.

### 23.9.2.2 SLIMbus Functional Interface

Table 23-647 describes the SLIMbus1 interface.

**Table 23-647. SLIMbus1 Signals Description**

Signal	I/O	Description	Value at Reset
abe_slimbus1_data	I/O	SLIMbus1 DATA pad	1
abe_slimbus1_clock	I/O	SLIMbus1 CLOCK pad	1

Table 23-648 describes the SLIMbus2 interface.

**Table 23-648. SLIMbus2 Signals Description**

Signal	I/O	Description	Value at Reset
slimbus2_data	I/O	SLIMbus2 DATA pad	1
slimbus2_clock	I/O	SLIMbus2 CLOCK pad	1

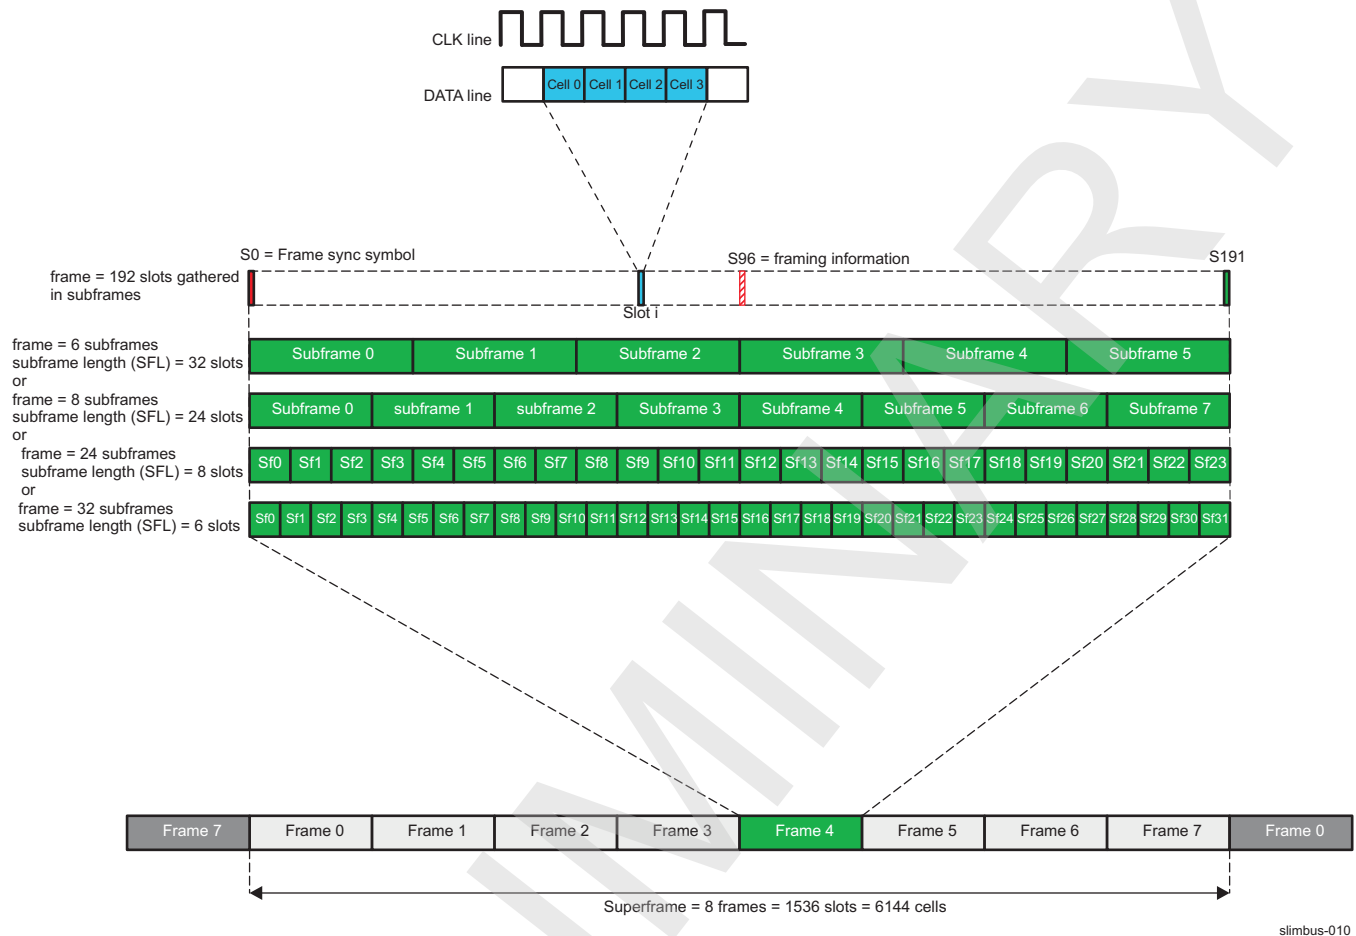

### 23.9.2.3 SLIMbus Protocols and Data Formats

#### 23.9.2.3.1 Frame Structure

The SLIMbus bitstream is transferred in time-division multiplexing (TDM) organization. TDM is a type of multiplexing in which two or more bitstreams are transferred apparently simultaneously as subchannels in one communication channel, but are physically taking turns on the channel. This organization allows SLIMbus to transfer control, data, and configuration information through only one DATA signal. The organization of information on the bus is called a frame structure. The frame structure is composed of five building blocks: cells, slots, subframes, frames and superframes.

- A cell is the smallest division of the SLIMbus data stream. A cell is defined as the region of the DATA line signal that lies between two consecutive positive edges of the CLK signal.
- A slot is a group of four contiguous cells. It is at the slot level that the SLIMbus DATA signal is time division-multiplexed between different channels.
- A frame is a group of 192 contiguous slots (768 cells). The first slot of each frame carries the frame-sync symbol.
- A subframe is the division of the frame structure at which control space and, if present, data space are interleaved. The subframe length can be 6, 8, 24, or 32 slots (24, 32, 96, and 128 cells).
- A superframe is composed of eight consecutive frames and contains a complete set of Framing Information.

Figure 23-210 shows the organization of the frame structure.

**Figure 23-210. SLIMbus Frame Structure Overview**

### 23.9.2.3.2 Control and Data Channels

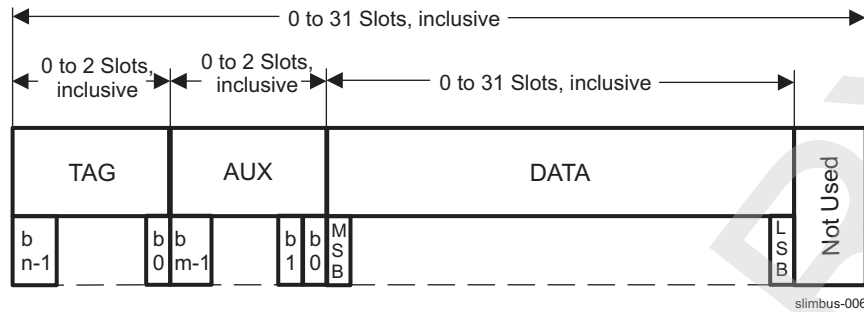

A frame is divided into two parts: the control space and the data space. The control space contains the information needed for a device to discover the bus state, to track messages, and for the messages themselves. The control space size is programmable by setting the control space width (number of control space slots per subframe) and the subframe length. Data space is interleaved with control space at the subframe level. Slots not explicitly allocated to control space are considered data space. The active manager can organize these slots into data channels to transport application-specific data streams between devices on the bus. Data space can contain up to 256 data channels.

A data channel is a stream of one or more contiguous slots organized in a consistent data structure that repeats at a fixed interval. The largest possible group of contiguous slots within a data channel is known as a segment.

A data channel connects one data source port and one or several data sink ports, depending on the protocol used. A port can be connected only to a single data channel at a time.

A segment is composed of three fields: TAG, auxiliary information (AUX), and data fields. These fields are organized within the segment, as shown in [Figure 23-211](#). The exact composition of the segment depends on the transport protocol.

Figure 23-211. Segment Organization

### 23.9.2.3.3 SLIMbus Transfer Protocols

The SLIMbus module supports seven the following protocols:

- Isochronous
- Pushed
- Pulled
- Asynchronous
  - Simplex
  - Half-duplex
- Extended asynchronous
  - Simplex
  - Half-duplex

Table 23-649. SLIMbus Transfer Protocols

Transfer Protocol	Multicast Capability
Isochronous transfer protocol	Yes
Pushed transfer protocol	Yes
Pulled transfer protocol	No
Asynchronous transfer protocols	No
Extended asynchronous transfer protocols	No

#### 23.9.2.3.3.1 Isochronous Transfer Protocol

The isochronous transfer protocol is a unidirectional, streaming, multicast communication mode. Data is to be present in all allocated segments (this transfer protocol has no TAG field).

- 100 percent of the bandwidth is usable for AUX + DATA slots (no control TAG overhead).
- Because no flow control exists, multiple data sinks may be connected to the same data source (multicast capability).
- The range of possible presence rates (number of segments per second) is limited to simple ratios of the SLIMbus clock. If several data streams with incompatible presence rates must be multiplexed over the same bus, no combination of isochronous-based schedulings works. In those cases, the pushed or pulled transfer protocol must be used.

#### 23.9.2.3.3.2 Pushed Transfer Protocol

The pushed transfer protocol is unidirectional, multicast, and controlled by the data source (transmitter), which pushes data toward the data sink (receiver). The presence of valid data in a segment is indicated by the presence (P) bit in the TAG field, driven by the source. The TAG field is composed of four bits: one reserved, one strobe (STR) bit, one reserved, and one presesnce (P) bit.

- The pushed data source is the master of the data flow through the presence (P) bit .
- The pushed data sink is slaved to the presence (P) bit..

- The TAG control field creates a 1-slot overhead per segment. The rest of the segment is usable for AUX + DATA slots.
- Because the flow control is generated by the source with no feedback from the sink, multiple data sinks may be connected to that source (multicast capability).
- The presence rate can be modulated at will from 0 (no data at all) to the full segment rate (data present in all segments) according to the requirement. Intermediate settings allow several streams with incompatible presence rates to be multiplexed over the same bus, at the cost of less than 100 percent bandwidth utilization (for example, a 44.1-kHz sample flow transmitted over a reserved 48-kHz data channel).

### 23.9.2.3.3.3 Pulled Transfer Protocol

The pulled transfer protocol is unidirectional, unicast, and controlled by the data sink (receiver), which pulls data from the data transmitter (source). The presence of valid data in a segment is indicated by the presence bit (P) in the TAG field, driven by the source. The TAG field is composed of four bits: one reserved, one sample request (SRQ) bit, one reserved, and one presence (P) bit.

- The pulled data sink is the master of the data flow through the (SRQ bit, itself determining the value of the presence bit (P), driven by the data source.
- The pulled data source is slaved to the SRQ bit.
- The TAG control field creates a 1-slot overhead per segment. The rest of the segment is usable for AUX + DATA slots.
- Because the flow control is generated by the sink with feedback from the source, only a single data sink may be connected to that source (unicast-only, no multicast capability).
- The presence rate can be modulated at will from 0 (no data at all) to the full segment rate (data present in all segments) according to the requirement. Intermediate settings allow several streams with incompatible presence rates to be multiplexed over the same bus, at the cost of less than 100 percent bandwidth utilization (for example, a 44.1-kHz sample flow transmitted over a reserved 48-kHz data channel).

### 23.9.2.3.3.4 Asynchronous Transfer Protocols

The asynchronous transfer protocols are typically used for on-demand, packet-based data transfers (that is, nonstreaming). Because the SLIMbus protocol and architecture are optimized for data streaming scenarios, asynchronous protocols are considered a useful extension rather than a central feature of the SLIMbus. An asynchronous data channel gets the same periodic, reserved, fixed-bandwidth slot allocation as a streaming (for example, isochronous) data channel.

An asynchronous data channel is a point-to-point (unicast) communication link between a primary owner device and a secondary owner device.

A half-duplex asynchronous channel is a bidirectional data channel.

- A handshake protocol is used to determine the direction of the channel through its ownership. The channel owner is the data source, and the other is the sink.
- Once the ownership (data direction) is determined, both source and sink can regulate the flow of data, depending on data availability (source) and free buffer availability (sink).
- Half-duplex ports can be used when bandwidth is sparse (compare simplex and full duplex).
- However, each half-duplex port requires two data channel agents (with FIFO and control logic) inside the controller, one in each direction, contrary to all other asynchronous modes and transfer protocols. Those two associated agents must be configured coherently.

A simplex asynchronous channel is a unidirectional data channel, a simplified version of the half-duplex channel defined perviously. The ownership is never given to the secondary owner.

- Secondary owner never requests the channel. As a consequence, the roles are never exchanged: the primary owner is always data source, and the secondary owner always data sink.
- Simplex ports are used in pairs of opposite directions to implement full-duplex communication, where each direction has its own reserved bandwidth. As far as the controller is concerned, the two simplex links are treated as fully independent data channels, with independent configurations; only the higher layers (software) associate the two.

- Two simplex ports use the same number of data channel agents (that is, FIFOs and control logic) as a single half-duplex port (two per controller in each case; the only difference is in the bandwidth management).

#### **23.9.2.3.3.5 Extended Asynchronous Transfer Protocols**

The extended asynchronous transfer protocols are extensions of the plain asynchronous transfer protocol. The main features are retained: point-to-point (unicast) between a primary and a secondary owner, simplex (unidirectional) or half-duplex (bidirectional), and so on.

The difference lies in a more flexible management of the DATA slots: In the plain asynchronous TP, each segment contains no data (presence [P] bit = 0) or a fixed amount of data ( $P = 1$ ), preconfigured for all segments. In the extended asynchronous mode, a number of valid bytes (NVB) 4-bit field is added before each segment, in a second TAG slot, to indicate a variable number of significant DATA slots (the granularity is 1 byte = 2 slots).

---

**NOTE:** AUX slots (when present; not in the current implementation) are not counted in NVB, just as they are not counted in DL in the plain asynchronous TP.

---

#### **23.9.2.3.4 Half-Duplex Versus Full-Duplex Asynchronous Configurations**

Half-duplex and full-duplex modes are similar in their operation, in that they use two data channel agents (FIFOs and associated control hardware) in opposite directions (one TX, one RX) to transmit and receive data over a bidirectional, unicast (point-to-point) asynchronous link. However, there are differences:

- The half-duplex setup uses a single data channel (in the SLIMbus sense); that is, a single reserved data space segment allocation, used alternately in both directions, according to the dynamic ownership negotiated in the TAG slots.
- The full-duplex setup uses two data channels (in the SLIMbus sense); that is, two separate reserved data space segment allocations, each used in a fixed direction (opposite of the other) (that is, with no ownership change).

### 23.9.3 SLIMbus Integration

Figure 23-212 and Figure 23-213 show the integration of the two SLIMbus module instantiations in the device. The SLIMBUS1 module is part of the ABE module

Figure 23-212. SLIMBUS1 Integration

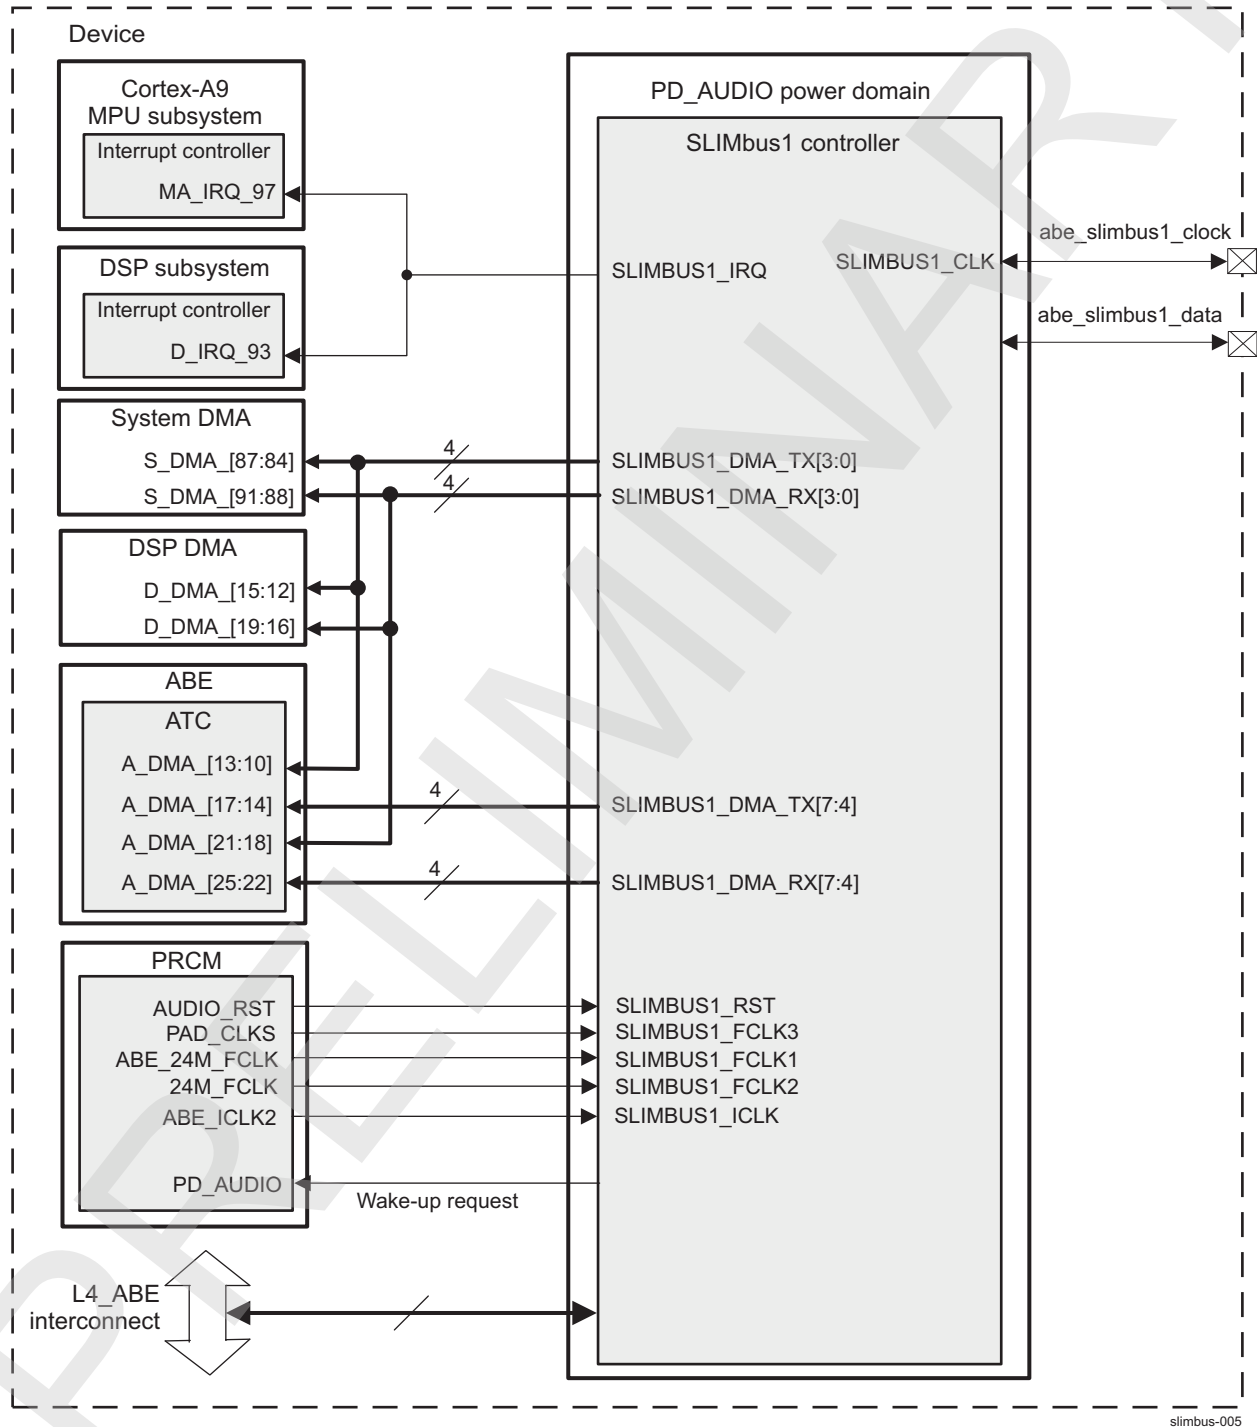

Figure 23-213. SLIMBUS2 Integration

slimbus-003

Table 23-650 through Table 23-652 summarize the integration of the modules in the device.

Table 23-650. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect

**NOTE:**

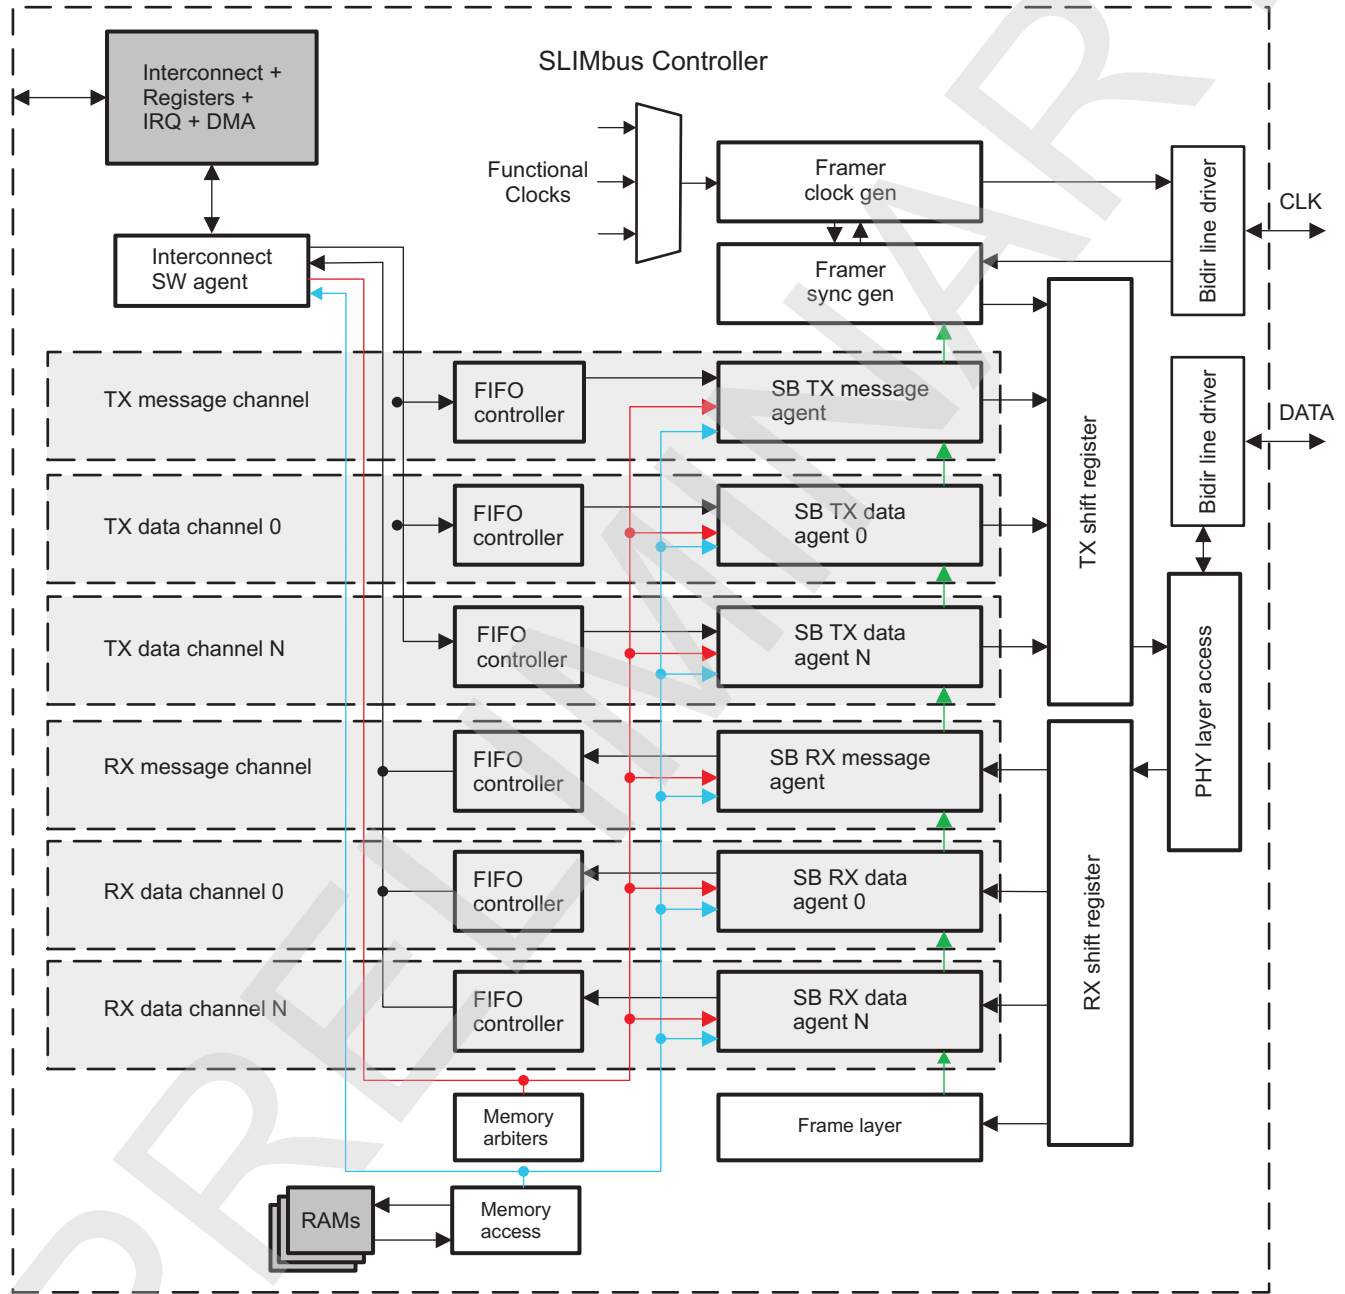

- For the description of the interrupt, see [Section 23.9.4.12, Interrupt Service Routines](#), and [Chapter 17, Interrupt Controllers](#).
- For the description of the DMA, see [Section 23.9.4.5.2, Data Input/Output: DMA Request Mode](#), and [Chapter 16, SDMA](#).

### 23.9.4 SLIMbus Functional Description

#### 23.9.4.1 SLIMbus Block Description

Figure 23-214 shows the the overall architecture of a SLIMbus module.

Figure 23-214. SLIMbus Block Diagram

- The red arrows represent the shared memory arbitration interface, from the arbiter to each agent.
- The blue arrows represent the shared memory access interface, from the memory access module to each agent.
- The green arrows represent the frame layer sync information broadcasted to all SB-side agents.

### 23.9.4.2 SLIMbus Clock Configuration

Most of the SLIMbus module runs off two main clocks: the L4 interface clock for the data input and output registers, and the control and status control registers; and the SLIMbus clock, taken from the serial interface (CLK line) for the SLIMbus-side logic.

The SLIMbus controller operates as clock source component (active framer), which drives the SLIMbus clock line CLK, or as clock receiver component, which gets its clock from the same CLK line.

- As a clock receiver, the module has by definition no control over the clock activity and can perform required operations based on that. Even clock pause is mostly transparent as far as the receiver logic is concerned (that is, everything happens as if time had stopped at the clock pause, and activity resumes seamlessly upon clock restart).
- As a clock source (also called active framer), the module relies on a local functional clock to drive the SLIMbus clock line. Such a functional clock is selected out of the available clock inputs. The appropriate input is expected to be active whenever it is needed (that is, when selected and used to run the SLIMbus clock and/or the module internal logic). In this case, the SLIMbus clock output is generated by selecting and dividing one functional clock input provided to the controller. Internal logic selects and divides the appropriate one depending on the SLIMbus configuration.

### 23.9.4.3 Software Reset

The [SLIMBUS\\_CMP\\_SYSCONFIG\[1\] SOFTRESET](#) bit controls the software reset; writing 1 to this bit starts a soft reset sequence.

### 23.9.4.4 System Power Management and Wakeup

#### 23.9.4.4.1 Wake-Up Request

Both SLIMbus controllers are wake-up capable.

There are several levels of wake-up capability:

- Most IRQ events are potential wake-up sources, because they can occur while the external interface is idle, assuming the external and SLIMbus clocks are still running.
- The clock restart IRQ event (the [SLIMBUS\\_FR\\_INFO\[5\] CLOCK\\_RESTART](#) bit) following a clock pause is the only one that can take place when all module clocks are stopped.

#### 23.9.4.4.2 Power Management

[Table 23-653](#) describes power-management features available for the SLIMbus module.

---

**NOTE:** For the description of the IdleMode feature, see [Chapter 3, Power, Reset, and Clock Management](#).

---

**Table 23-653. Local Power-Management Features**

Feature	Registers	Description
Clock auto gating	<a href="#">SLIMBUS_CMP_SYSCONFIG[8] AUTOGATINGDISABLE</a>	Internal clock autogating is intended to conserve power when the module is not in use.
Slave idle modes	<a href="#">SLIMBUS_CMP_SYSCONFIG[3:2] IDLEMODE</a>	Force-idle, no-idle, smart-idle, and smart-idle wake-up-capable modes are available.
Wake-up sources enable	<a href="#">SLIMBUS_FR_INFO[5] CLOCK_RESTART</a> and most IRQ events	See <a href="#">Section 23.9.4.4.1</a>

#### 23.9.4.4.3 SLIMbus Boot and Reset Procedures

The SLIMbus standard defines different levels of resets and default states from which to boot. They are implemented by a mix of software and hardware.

**NOTE:** This does not include the module-wide software or hardware resets of the controller, which simply wipe off the entire logic with no consideration for any potentially ongoing SLIMbus operation.

Table 23-654 summarizes the control bit fields to set in the various reset and/or boot sequences. Any combination other than the ones described here may yield unpredictable results.

**Table 23-654. Reset and Boot Control Summary**

Register / Field	SLIMBUS_FR_CONTROL		SLIMBUS_FL_CONTROL		
	Boot	bus_reset	Boot	bus_shutdown	force_reconfigure <sup>(1)</sup>
Clock receiver boot <sup>(2)</sup>			1		1
Clock source boot	1				1
Clock receiver component reset <sup>(2) (3)</sup>			1		1
Clock source component reset		1			1
Bus reset <sup>(4) (5)</sup>		1			
Bus shutdown <sup>(4)</sup>				1	

- (1) When used, the SLIMBUS\_FL\_CONTROL[2] FORCE\_RECONFIGURE bit must be set (written to 1) last, because its action can be immediate. Other control bits can be set in any order.
- (2) The controls for boot and component reset look identical for the clock receiver. The difference is in the initial state of the component: in the first case, the component is in the undefined state (not started), in the second case it is operational.
- (3) The clock receiver component reset case shown here corresponds to the reception by the component interface of the RESET\_DEVICE. In the two other cases, a bus reset is detected and the hardware automatically goes to the correct state.
- (4) The bus reset and shutdown belong to a reconfiguration (message) sequence and take place on the reconfiguration boundary: the SLIMBUS\_FL\_CONTROL[2] FORCE\_RECONFIGURE is therefore not used.
- (5) The bus reset is executed only by the clock source (active framer).

**23.9.4.4.3.1 Clock Receiver Component Boot**

A clock receiver boot sequence is initiated when a component that is not the default active framer decides to join the SLIMbus. Provided the clock line is driven (that is, a framer is active), the clock receiver must eventually acquire the synchronization.

Clock receiver boot sequence:

- Initial state: Out of hardware module reset or following a SLIMbus shutdown
- Write 1 to the SLIMBUS\_FL\_CONTROL[0] BOOT bit to start the clock receiver.
- Write 1 to the SLIMBUS\_FL\_CONTROL[2] FORCE\_RECONFIGURE bit.

**23.9.4.4.3.2 Clock Source Component Boot**

Source component is, by definition, the component including the active framer (that is, the clock driver). A clock source boot sequence is initiated when a component that is the default active framer joins the SLIMbus. The clock source drives the clock line and runs the SLIMbus boot sequence, allowing the connected clock receivers to synchronize to it.

**NOTE:** The component knows in advance that it is the only default active framer, in charge of booting the bus: That information must be available for the component, as well as the default SM, CG, and RF configuration parameters.

Clock source boot sequence:

- Initial state: The component is the designated default active framer and is out of hardware module reset or follows a SLIMbus shutdown.
- Write 1 to the SLIMBUS\_FR\_CONTROL[0] BOOT bit.
- Write the basic bus configuration, to be used by the active framer device to generate the clock and the framing channel contents:
  - Subframe mode (M) in the SLIMBUS\_FL\_SM[4:0] SM bit field: Sets the control space width and subframe length

- Clock gear (G) in the [SLIMBUS\\_FL\\_CG\[3:0\]](#) CG bit field: The root/SLIMbus frequency ratio is defined as  $2^{(10-CG)}$
- Root frequency (F) in the [SLIMBUS\\_FL\\_RF\[3:0\]](#) RF bit field: Sets the root frequency
- Clock source selection, in the [SLIMBUS\\_FR\\_CLOCK\\_SOURCE\[5:3\]](#) CLKSEL and [SLIMBUS\\_FR\\_CLOCK\\_SOURCE\[2:0\]](#) CLKDIV bit fields
- The relationships (and limitations) between CG, RF, and the clock source selection also apply here.
- Write 1 to the [SLIMBUS\\_FL\\_CONTROL\[2\]](#) FORCE\_RECONFIGURE bit to trigger the sequence execution
- The clock source starts immediately and eventually drives the CLK line and allows other components (clock receivers) to join the bus.

#### 23.9.4.4.3.3 Bus Reset

A bus reset is a specific DATA and CLK sequence run by the active framer, scheduled after the bus has already booted, and which causes all components of the bus to reset. For more information about the bus reset detection mechanism, see [Section 23.9.4.4.3.4, Component Reset](#).

The bus reset is requested by the manager device through a reconfiguration sequence, and is run by the active framer starting at the following reconfiguration boundary.

Bus reset sequence, to be executed by all components:

- Write 1 to the [SLIMBUS\\_FR\\_CONTROL\[1\]](#) BUS\_RESET bit.
- Wait for the end of the reconfiguration sequence to execute:
  - On the clock source (active framer), this must trigger a bus reset sequence.
  - On any other device (that is, a clock receiver), this must have no direct effect (other than clearing the [SLIMBUS\\_FR\\_CONTROL\[1\]](#) BUS\_RESET bit).
  - Because all bus devices are being reset (bus is rebooted, almost from the beginning), the configuration (M, G, F parameters) can change (because those parameters must be reacquired by all attached devices as part of the resynchronization sequence, this is not a problem).

#### 23.9.4.4.3.4 Component Reset

A component reset implies the (device) reset of all devices within that component. When a component reset condition is detected, software must therefore run the device reset sequence defined in [Section 23.9.4.4.3.5, Device Reset](#), as many times as necessary. Additional operations are also required.

A component reset has two possible causes:

- Bus reset sequence detected
- Interface device of the local component receives a reset order. (This is not a reconfiguration message; that is, the reset is effective immediately upon reception. Nevertheless, a specific action is needed to perform the device reset:)
  - Use the [SLIMBUS\\_FL\\_CONTROL\[1\]](#) COMPONENT\_RESET bit.
  - If the component is a clock receiver (clock receiver FSM), the sequence is :
    - Write 1 to the [SLIMBUS\\_FL\\_CONTROL\[0\]](#) BOOT bit.
    - Write 1 to the [SLIMBUS\\_FL\\_CONTROL\[2\]](#) FORCE\_RECONFIGURE bit to trigger the reset execution.
  - If the component is the active framer (clock source FSM), the sequence is :
    - Write 1 to the [SLIMBUS\\_FR\\_CONTROL\[1\]](#) BUS\_RESET bit.
    - Write 1 to the [SLIMBUS\\_FL\\_CONTROL\[2\]](#) FORCE\_RECONFIGURE bit to trigger the reset execution.
    - The effect of a clock source component reset is the same as a bus reset, except it takes place immediately instead of waiting for a reconfiguration boundary.

#### 23.9.4.4.3.5 Device Reset

A device reset can have several causes:

- Component reset of the receiver component containing that device, caused by a bus reset reconfiguration message. If the cause of the device reset is a component reset, the sequence defined in [Section 23.9.4.4.3.4, Component Reset](#), is applied.
- A reset order targeted at the device itself. (This is not a reconfiguration message; that is, it is effective immediately upon reception. In this case, no additional action is required.)

The following sequence must be executed for all devices:

- Release the logical address (LA) of the device by clearing (writing 0 to) the [SLIMBUS\\_DEV\\_LA\\_i\[8\]](#) LA\_ENABLE bit. It is assumed that the [SLIMBUS\\_DEV\\_LA\\_i\[9\]](#) EA\_ENABLE bit remains set (1). The device returns to the default, nonenumerated state where it is identified by its hard-coded enumeration address (EA). The [SLIMBUS\\_DEV\\_LA\\_i\[7:0\]](#) LA bit may be assigned to another device by the bus manager (that is, keeping track of all device resets).
- The following hardware bits must also be cleared (by writing 1) when the device to which they belong (identified by the message target LA) is being reset:
  - The [SLIMBUS\\_FR\\_INFO\[2\]](#) FS, [SLIMBUS\\_FR\\_INFO\[1\]](#) FI, and [SLIMBUS\\_FR\\_INFO\[0\]](#) GC\_TX\_COL bits (framer device-specific IEs)
  - The [SLIMBUS\\_FL\\_INFO\[4\]](#) DATA\_SLOT\_OVERLAP bit (interface device-specific IE)
  - The [SLIMBUS\\_FL\\_INFO\[2\]](#) LOST\_FS, [SLIMBUS\\_FL\\_INFO\[1\]](#) LOST\_SFS, and [SLIMBUS\\_FL\\_INFO\[0\]](#) LOST\_MS bits (interface device-specific IEs)
  - The [SLIMBUS\\_SMR\\_INFO\[0\]](#) MC\_TX\_COL, [SLIMBUS\\_SMT\\_INFO\[0\]](#) MC\_TX\_COL bit (primitives of interface device-specific IE)
  - The [SLIMBUS\\_DCT\\_INFO\\_j\[0\]](#)/[SLIMBUS\\_DCR\\_INFO\\_j\[0\]](#) DATA\_TX\_COL bit (generic device IEs)
- Reset all pending reconfiguration parameters by writing 1 to the [SLIMBUS\\_FL\\_CONTROL\[7\]](#) CLEAR\_RECONFIGURATION bit (see [Section 23.9.4.4.4](#)).
- Reset all device ports (if any), as explained in [Section 23.9.4.4.3.6, Port Reset](#).

#### **23.9.4.4.3.6 Port Reset**

A port reset can have several causes:

- Device reset of the device to which the port belongs, which may be part of a wider component of the bus reset
- Synchronization loss. Although all ports are reset, this is not equivalent to a device reset, because logical addresses are not cleared.
- Specific software messages reception

#### **23.9.4.4.3.7 Bus Shutdown**

A bus shutdown stops definitively all SLIMbus activity (CLK and DATA) and brings the bus back to its original (preboot) state. When the shutdown is executed, the system must reboot from scratch.

The bus shutdown is requested by the manager device through a reconfiguration sequence.

Bus shutdown sequence:

- Write 1 to the [SLIMBUS\\_FL\\_CONTROL\[6\]](#) BUS\_SHUTDOWN bit. This is valid for an active framer (clock source) or a clock receiver.
- Wait for the end of the reconfiguration sequence to execute.
- Beyond that point, the bus is down and can be restarted only by a boot sequence.

#### **23.9.4.4.4 SLIMbus Reconfigure Parameters**

During a reconfiguration message sequence, the controller accumulates parameter changes to be applied at the following reconfiguration boundary. If the sequence does not complete correctly, all changes are discarded. In specific boot and reset cases, the parameters are also set or reset automatically.

This section provides an overview of all the configuration register fields and their use.

Writing 1 to the [SLIMBUS\\_FL\\_CONTROL\[7\]](#) CLEAR\_RECONFIGURATION bit has an immediate effect on the configuration registers.

- The following registers fields revert to their current value; that is, the value currently used for SLIMbus operations. The value previously written in is discarded.
  - The [SLIMBUS\\_FL\\_SM\[4:0\]](#) SM bit field: Sets the control space width and subframe length.
  - The [SLIMBUS\\_FL\\_CG\[3:0\]](#) CG bit field: The root/SLIMbus frequency ratio is defined as  $2^{(10-G)}$ .
  - The [SLIMBUS\\_FL\\_RF\[3:0\]](#) RF bit field: Sets the root frequency
  - The [SLIMBUS\\_FR\\_CLOCK\\_SOURCE\[5:3\]](#) CLKSEL: Clock input source selection
  - [SLIMBUS\\_FR\\_CLOCK\\_SOURCE\[2:0\]](#) CLKDIV bit field: Root divider ratio, applied on clock input to obtain root clock, to be used at next reconfiguration boundary. Input/ root frequency ratio is defined as  $2^{(CLKDIV-1)}$ .
  - The [SLIMBUS\\_DCT\\_CONFIG1\\_j\[31\]/SLIMBUS\\_DCR\\_CONFIG1\\_j\[31\]](#) ENABLE bit (this field is also cleared when the superframe or frame sync is lost): Data channel agent enabling control
  - The [SLIMBUS\\_DCT\\_CONFIG1\\_j\[15\]/SLIMBUS\\_DCR\\_CONFIG1\\_j\[15\]](#) CL bit: Channel link configuration mode selection
  - The [SLIMBUS\\_DCT\\_CONFIG1\\_j\[26:20\]/SLIMBUS\\_DCR\\_CONFIG1\\_j\[26:20\]](#) PR bit field: Presence rate configuration
  - The [SLIMBUS\\_DCT\\_CONFIG1\\_j\[3:0\]/SLIMBUS\\_DCR\\_CONFIG1\\_j\[3:0\]](#) TP bit field: Transfer protocol selection
  - The [SLIMBUS\\_DCT\\_CONFIG2\\_j\[11:0\]/SLIMBUS\\_DCR\\_CONFIG2\\_j\[11:0\]](#) SD bit field: Segment distribution
- The following register bits are cleared to 0. They correspond to features enabled for the upcoming reconfiguration boundary, and that are discarded here.
  - The [SLIMBUS\\_FR\\_CONTROL\[1\]](#) BUS\_RESET bit: Bus reset request control
  - The [SLIMBUS\\_FR\\_CONTROL\[0\]](#) BOOT bit: Initiate an active framer (clock source) boot sequence for the component when the component is default active framer.
  - The [SLIMBUS\\_FL\\_CONTROL\[6\]](#) BUS\_SHUTDOWN
  - [SLIMBUS\\_FL\\_CONTROL\[0\]](#) BOOT bit: Boot the component when not in active framer mode.
  - The [SLIMBUS\\_FL\\_CONTROL\[4\]](#) KILL\_SFS bit is set when the reconfiguration sequence terminates incorrectly (in that case the bit must be set after the clear-up). Forces immediate frame synchronization loss.
  - The [SLIMBUS\\_FL\\_CONTROL\[7\]](#) CLEAR\_RECONFIGURATION bit itself; that is, the bit never reads out 1.
  - The [SLIMBUS\\_FR\\_FRAMER\\_HANDBOVER\[12\]](#) HANDBOVER\_ENABLE bit: Enable framer handover, upon NEXT\_ACTIVE\_FRAMER(NCO,NCI) reception.
  - The [SLIMBUS\\_FR\\_CLOCK\\_PAUSE\[0\]](#) CLOCK\_PAUSE bit: Controls clock pause/restart
- The following bit fields do not change, although they are updated as part of the reconfiguration message sequence:
  - The [SLIMBUS\\_FR\\_FRAMER\\_HANDBOVER\[11:0\]](#) NCO\_NCI bit field: The value is don't care as long as [SLIMBUS\\_FR\\_FRAMER\\_HANDBOVER\[12\]](#) HANDBOVER\_ENABLE = 0, and is overwritten if a new handover is scheduled.
  - The [SLIMBUS\\_FR\\_CLOCK\\_PAUSE\[2:1\]](#) TRT bit field: The value is don't care as long as [SLIMBUS\\_FR\\_CLOCK\\_PAUSE\[0\]](#) CLOCK\_PAUSE = 0, and is overwritten if a new pause is scheduled.

#### 23.9.4.5 Data Channels (Ports) Management

Ports (contained in devices) are associated with data channels that connect several ports, typically one output port on a data source device and one or more inputs ports on a data sink device, over periodically scheduled data segments and using a given transfer protocol (TP).

##### 23.9.4.5.1 Data input/output: manual mode

A data channel agent FIFO stores a whole number of FIFO words. A FIFO word is a chunk of data that contains the AUX and DATA information of one SLIMbus data segment, with the following properties:

- The FIFO word size minimum is 4 bits (one slot) in the current implementation, as defined in the MIPI SLIMbus standard 1.01.00; they are of little practical use.

- The FIFO word size maximum is 32 bits (eight slots) in the current implementation, equal to one physical FIFO RAM word and to one read/write access. Larger segment sizes (up to 31 slots = 124 bits) segments are defined in the MIPI SLIMbus standard version 1.01.00, but they are not implemented here.
- Between the minimum and maximum values, the FIFO word size is programmable, with a slot (that is, 4 bits) granularity.
- The AUX information is a field of 0, 1, or 2 slots (that is, 0, 4, or 8 bits) transmitted immediately before the DATA slots. All sizes are supported by current implementation. It is stored and managed along with the DATA by the module FIFOs.
- The DATA information is a field of 0 to 31 slots in the MIPI SLIMbus standard version 1.01.00, with slot granularity. This is implemented within the limits of the FIFO word size given previously, with AUX size + DATA size = FIFO word size; therefore, the DATA information is a field of 0 to 8 slots.
- The extended asynchronous transfer protocols (TP; that is, simplex and half-duplex) are exceptions to the previously discussed rules. In that case, the source device fills each segment with as many bytes as it deems necessary (provided it fits in the segment), and lets the sink device know how many through the TAG NVB field:
  - The source transmits as many whole FIFO words as it deems necessary. This implies that the FIFO word is a byte multiple (that is, an even number of 4-bit slots).
  - The sink receives a whole number of bytes, which it stores in byte-size FIFO words.
  - AUX is not applicable and is not supported in these modes.

Each read (or write) access to the appropriate [SLIMBUS\\_DCR\\_DATA\\_j](#) (respectively, [SLIMBUS\\_DCT\\_DATA\\_j](#)) removes (respectively, adds) one FIFO word from RX (TX) FIFO #N. [Table 23-655](#) lists examples of possible FIFO word mappings (with the AUX and DATA slots indicated as A() and D()) inside 32-bit read and write accesses.

**NOTE:** The transmission over the SLIMbus serial interface is always A(0) to A(N1), and then D(0) to D(N2); that is, MSB to LSB.

**Table 23-655. Examples of AUX + DATA Mapping in 32-bit Read/Write Accesses**

FIFO Format	Word	FIFO Word Size (in Slots)	32-bit Access Read/Write Data (Bit Range)									
			31..28	27..24	23..20	19..16	15..12	11..8	7..4	3..0		
4-bit + 0 aux		1 (min)									D(0)	
8-bit + 0 aux		2									D(0)	D(1)
12-bit + 0 aux		3								D(0)	D(1)	D(2)
16-bit + 0 aux		4						D(0)	D(1)	D(2)	D(3)	
24-bit + 0 aux		6			D(0)	D(1)	D(2)	D(3)	D(4)	D(5)		
32-bit + 0 aux		8 (max)	D(0)	D(1)	D(2)	D(3)	D(4)	D(5)	D(6)	D(7)		
4-bit + 4 aux		2								A(0)	D(0)	
24-bit + 4 aux		7		A(0)	D(0)	D(1)	D(2)	D(3)	D(4)	D(5)		
28-bit + 4 aux		8 (max)	A(0)	D(0)	D(1)	D(2)	D(3)	D(4)	D(5)	D(6)		
4-bit + 8 aux		3							A(0)	A(1)	D(0)	
24-bit + 8 aux		8 (max)	A(0)	A(1)	D(0)	D(1)	D(2)	D(3)	D(4)	D(5)		

### 23.9.4.5.2 Data Input/Output: DMA Request Mode

The DMA mode reuses all the features of the manual mode defined in [Section 23.9.4.5.1](#), but adds a DMA request generation mechanism to offload the data manipulation task to an external (off-module) DMA controller. As far as the FIFOs themselves are concerned, the accesses are unchanged. For more information about the DMA controller configuration see [Chapter 16, SDMA](#).

DMA data channels can be enabled by the [SLIMBUS\\_CMP\\_DMAENABLE\\_SET](#) register and disabled by the [SLIMBUS\\_CMP\\_DMAENABLE\\_CLR](#) register.

### 23.9.4.5.3 Data Channel Agent FIFO Control and Status

Each data channel agent is associated with a FIFO, fixed in either TX or RX direction. All TX FIFOs are mapped to a shared buffer space, all RX FIFOs to another shared buffer space. FIFO sizes are software-programmable.

A FIFO must be configured before the data channel is enabled, depending on system-related parameters. For instance, more or less FIFO depth may be required. More FIFO is desirable to prevent underflow/overflow errors in a jittery transmission, but may also carry an unacceptable latency penalty in a voice stream. In any case, FIFO depth is beyond the SLIMbus protocol.

### 23.9.4.6 FIFO Management

The SLIMbus controller includes two FIFOs, used to buffer transmit/receive data/messages. The SLIMBUS1 FIFO is 32 bytes for TX and 32 bytes for RX. The SLIMBUS2 FIFO is 64 bytes for TX and 64 bytes for RX. FIFO size information is given by the `SLIMBUS_CMP_HWINFO[19:12]` RRSZ and [11:4] TRSZ bit fields.

FIFOs are connected to SLIMbus-side agents, which transmit and receive data on the serial SLIMbus DATA line. All ports are synchronous to the SLIMbus clock. The numbers of data channel agents are given by `SLIMBUS_CMP_HWINFO[27:24]` TDC and [23:20] RDC bit fields.

A segment (see [Section 23.9.2.3.2](#)) passes through the internal RX and TX FIFOs, where it is stored in FIFO words. The size of the FIFO word, expressed in 4-bit slots, is configurable by software. The FIFO word size is hardware-calculated with the following parameters:

- The `SLIMBUS_DCR_CONFIG1_j[9:5]`/`SLIMBUS_DCT_CONFIG1_j[9:5]` SL bit field: Channel segment length, in slots
- The `SLIMBUS_DCR_CONFIG1_j[14:10]`/`SLIMBUS_DCT_CONFIG1_j[14:10]` DL bit field: Channel data length, integer
- The `SLIMBUS_DCR_CONFIG1_j[3:0]`/`SLIMBUS_DCT_CONFIG1_j[3:0]` TP (tag\_length) bit field: Length of segment TAG field, function of the channel transfer protocol, in slots.
- The `SLIMBUS_DCR_CONFIG1_j[19:16]`/`SLIMBUS_DCT_CONFIG1_j[19:16]` AF (aux\_length) bit field: Length of segment AUX field, function of the channel auxiliary format, in slots.

The FIFO word size is computed as follows by the module hardware:

- if DL is equal to 0, FIFO word size = SL tag\_length(TP)
- if DL is not equal to 0, FIFO word size = aux\_length(AF) + DL

#### 23.9.4.6.1 FIFO Mapping

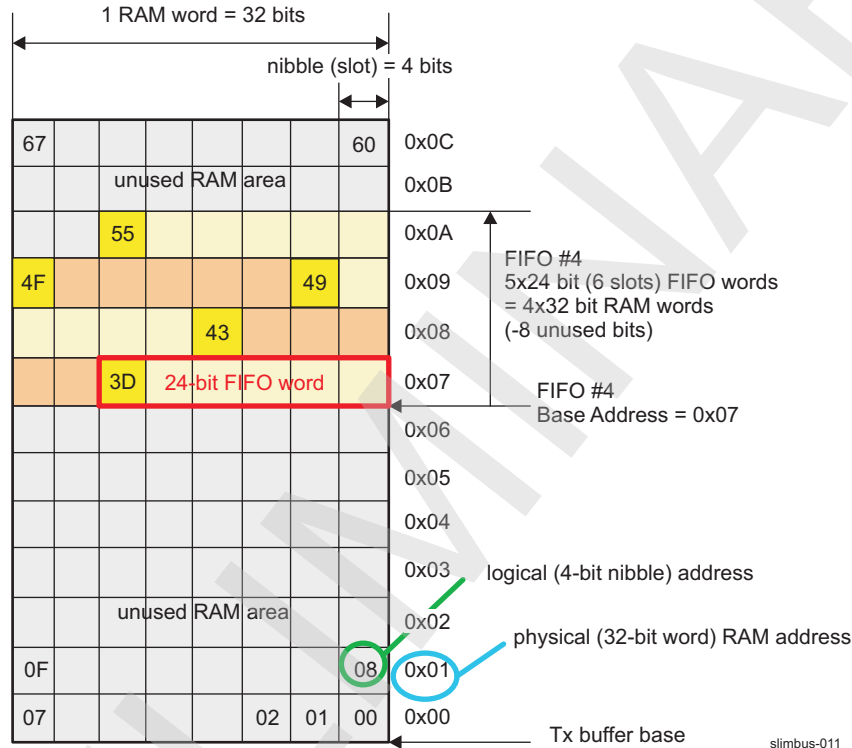

Each FIFO must be mapped in a free zone of the shared buffer before enabling, as follows:

- The `SLIMBUS_DCR_FIFO_SETUP2_j[7:0]` SIZE and/or `SLIMBUS_DCT_FIFO_SETUP2_j[7:0]` SIZE + 1: Capacity of FIFO in FIFO words. (The minimum setting recommended by the SLIMbus protocol is 4-word deep.)
- The `SLIMBUS_SMT_FIFO_SETUP[6:5]` SIZE\_HI/`SLIMBUS_SMR_FIFO_SETUP[6:5]` SIZE\_HI and `SLIMBUS_SMT_FIFO_SETUP[4:1]` SIZE\_LO/`SLIMBUS_SMR_FIFO_SETUP[4:1]` SIZE\_LO bit fields: Capacity of shared TX/RX FIFOs, in bytes, minus 1.
- The `SLIMBUS_DCR_FIFO_SETUP1_j[11:5]` BASE\_ADDR and/or `SLIMBUS_DCT_FIFO_SETUP1_j[11:5]` BASE\_ADDR bit fields: RX and/or TX data channel agent FIFO base address within shared RX/TX RAM
  - FIFO base nibble address = <FIFO base physical add> \* 8
  - FIFO top nibble address = <FIFO base nibble add> + (<FIFO size> \* <FIFO word size>) – 1
  - FIFO top physical address = <FIFO top nibble add> / 8
  - The next base physical address available to map another FIFO is the current FIFO top physical address + 1.
- The shared RX and TX buffers are independent; that is, the RX and TX FIFOs are mapped to separate address spaces.

[Figure 23-215](#) is an example mapping, with the following numerical configuration:

- Isochronous (SLIMBUS\_DCT\_CONFIG1\_4[3:0] TP = 0x0) TX FIFO using TX data channel agent 4
- FIFO word size: 6 slots = 24 bits, 20 DATA + 4 AUX (AF = 0xB, DL = 0x5)
- FIFO size: SLIMBUS\_DCT\_FIFO\_SETUP2\_4[7:0] SIZE = 4 (4 + 1 = 5 FIFO words stored in FIFO)
- FIFO base physical address: SLIMBUS\_DCT\_FIFO\_SETUP1\_4[11:5] BASE\_ADDR = 0x7 (= 7)
- FIFO base nibble address = 0x7 \* 8 = 0x38 (56)
- FIFO top nibble address = 0x38 + (0x5 \* 0x6) - 1 = 0x55 (= 85)
- FIFO top physical address = 0x55 / 0x8 = 0xA (= 10, this is a integer division)
- Next base physical address available to map another FIFO: 0xA + 1 = 0xB (= 11)

Figure 23-215. Example of FIFO Mapping in Shared Buffer

### 23.9.4.6.2 FIFO Status

The following receive-side status is available from the register fields:

- The `SLIMBUS_DCR_FIFO_STATUS_j[11:2]` RD\_LEVEL bit field: Number of FIFO words stored in RX FIFO #n. (This field is 1 bit longer than the size and threshold fields, because it ranges from 0 to the FIFO size, whereas the other fields range only from 0 to the FIFO size minus 1).
- The `SLIMBUS_DCR_FIFO_STATUS_j[0]` EMPTYbit: Active (1) status when RX FIFO #n contains 0 words (`rd_level = 0`); otherwise, low (0). A read may cause an underflow.
- The `SLIMBUS_DCR_FIFO_STATUS_j[1]` HILEVEL bit: Active (1) status when FIFO (read) level is (strictly) above the high threshold (that is, when there is more than a certain maximum of FIFO words stored in the FIFO). Equivalent to full in case `dma_hi_threshold = <FIFO size> - 1` (the maximum allowed value).

Table 23-656 shows numerical examples for all valid DMA threshold values and all levels in an RX FIFO of `<FIFO size> = 4` FIFO words (`SLIMBUS_DCR_FIFO_SETUP2_j[7:0] SIZE = 0x3`).

**NOTE:** The valid threshold range is from 0 to `<FIFO size> - 1`: the case `threshold = <FIFO size>` is functionally useless and impossible to program for maximum-sized FIFOs (because the `rd_level` field is 1 bit wider than the threshold fields).

**Table 23-656. HILEVEL/Empty Status of a 4-Word Receive FIFO, for all DMA Threshold Values**

rd_level (FIFO Words)	Empty	HILEVEL			
		thr = 0	thr = 1	thr = 2	thr = 3
0 (empty FIFO)	1	0	0	0	0
1	0	1	0	0	0
2	0	1	1	0	0
3	0	1	1	1	0
4 (full FIFO)	0	1	1	1	1

The following transmit-side status is available from the following bit fields:

- **SLIMBUS\_DCT\_FIFO\_STATUS\_j[11:2] WR\_LEVEL:** Number of free FIFO words in TX FIFO #n. (This field is 1 bit longer than the size and threshold fields, because it ranges from 0 to the FIFO size, whereas the other fields range only from 0 to the FIFO size minus 1).
- **SLIMBUS\_DCT\_FIFO\_STATUS\_j[0] FULL:** Active (1) status when TX FIFO #n contains <FIFO size> words (wr\_level = 0); otherwise, low (0). A write may cause an overflow.
- **SLIMBUS\_DCT\_FIFO\_STATUS\_j[1] LOLEVEL:** Active (1) status when FIFO (write) level is under (or equal to) the low threshold; that is, when there is less than a certain minimum of free FIFO words in the FIFO. Equivalent to full in case dma\_lo\_threshold = 0.

Table 23-657 shows numerical examples for all valid DMA threshold values and all levels in a TX FIFO of <FIFO size> = 4 FIFO words (SLIMBUS\_DCT\_FIFO\_SETUP2\_j[7:0] SIZE = 0x3).

**NOTE:** The valid threshold range is from 0 to <FIFO size> – 1: the case threshold = <FIFO size> is functionally useless and impossible to program for maximum-sized FIFOs (because the wr\_level field is 1 bit wider than the threshold fields).

**Table 23-657. LOLEVEL/Full Status of a 4-Word Transmit FIFO, for all DMA Threshold Values**

wr_level (FIFO Words)	Full	LOLEVEL			
		thr = 3	thr = 2	thr = 1	thr = 0
4 (empty FIFO)	1	1	1	1	0
3	0	1	1	1	0
2	0	0	1	1	0
1	0	0	0	1	0
0 (full FIFO)	0	0	0	0	1

### 23.9.4.6.3 FIFO Configuration

The bit fields used to configure the FIFOs are:

- **SLIMBUS\_DCR\_FIFO\_SETUP1\_j[11:5] BASE\_ADDR** and/or **SLIMBUS\_DCT\_FIFO\_SETUP1\_j[11:5] BASE\_ADDR:** RX and/or TX data channel agent FIFO base address within shared RX/TX RAM
- **SLIMBUS\_DCR\_FIFO\_SETUP1\_j[4:1] DMA\_REQ\_SIZE** and/or **SLIMBUS\_DCT\_FIFO\_SETUP1\_j[4:1] DMA\_REQ\_SIZE:** DMA request size minus 1, in accesses
- **SLIMBUS\_DCR\_FIFO\_SETUP2\_j[7:0] SIZE** and/or **SLIMBUS\_DCT\_FIFO\_SETUP2\_j[7:0] SIZE:** Capacity of FIFO in FIFO words. (The FIFO can be 1-word deep [the minimum possible value], but it is not recommended. The minimum setting recommended by the SLIMbus protocol is 4-word deep).
- **SLIMBUS\_DCR\_FIFO\_SETUP2\_j[15:8] SB\_TRESHOLD:** SLIMbus-side RX data channel agent FIFO threshold, used for SLIMbus reception.
- **SLIMBUS\_DCT\_FIFO\_SETUP2\_j[15:8] SB\_TRESHOLD:** SLIMbus-side TX data channel agent FIFO threshold, used for SLIMbus transmission.
- **SLIMBUS\_DCR\_FIFO\_SETUP2\_j[23:16] DMA\_TRESHOLD:** Software-side RX data channel agent FIFO low threshold. DMA write requests stop when **SLIMBUS\_DCR\_FIFO\_STATUS\_j[11:2] RD\_LEVEL** goes under threshold.
- **SLIMBUS\_DCT\_FIFO\_SETUP2\_j[23:16] DMA\_TRESHOLD:** Software-side TX data channel agent

FIFO low threshold. DMA write requests stop when `SLIMBUS_DCT_FIFO_STATUS_j[11:2]` `WR_LEVEL` goes under threshold.

- `SLIMBUS_DCR_FIFO_SETUP2_j[23:16]` `DMA_TRESHOLD`: Software-side RX data channel agent FIFO high threshold. DMA read requests start when `SLIMBUS_DCR_FIFO_STATUS_j[11:2]` `RD_LEVEL` goes above threshold.
- `SLIMBUS_DCT_FIFO_SETUP2_j[23:16]` `DMA_TRESHOLD`: Software-side TX data channel agent FIFO high threshold. DMA read requests start when `SLIMBUS_DCT_FIFO_STATUS_j[11:2]` `WR_LEVEL` goes above threshold.
- `SLIMBUS_DCR_FIFO_STATUS_j[0]` `EMPTY`: Active (1) status when RX FIFO #n contains 0 words (`rd_level = 0`), else low (0). A read may cause an underflow.
- `SLIMBUS_DCT_FIFO_STATUS_j[0]` `FULL`: Active (1) status when TX FIFO #n contains <FIFO size> words (`wr_level = 0`), else low (0). A write may cause an overflow.
- `SLIMBUS_DCT_FIFO_STATUS_j [1]` `LOLEVEL`: Active (1) status when FIFO (write) level is under (or equal to) the low threshold, that is, when there is less than a certain minimum of free FIFO words in the FIFO. Equivalent to full in case `dma_lo_threshold = 0`.
- `SLIMBUS_DCR_FIFO_STATUS_j[1]` `HILEVEL`: Active (1) status when FIFO (read) level is (strictly) above the high threshold, that is, when there is more than a certain maximum of FIFO words stored in the FIFO. Equivalent to full in case `dma_hi_threshold = <FIFO size> - 1` (the maximum allowed value).
- `SLIMBUS_DCR_FIFO_STATUS_j[11:2]` `RD_LEVEL`: Number of FIFO words stored in RX FIFO #n. (This field is 1 bit longer than the size and threshold fields, because it ranges from 0 to the FIFO size, whereas the other fields only range from 0 to the FIFO size minus 1).
- `SLIMBUS_DCT_FIFO_STATUS_j[11:2]` `WR_LEVEL`: Number of free FIFO words in TX FIFO #n. (This field is 1 bit longer than the size and threshold fields, because it ranges from 0 to the FIFO size, whereas the other fields only range from 0 to the FIFO size minus 1).

#### 23.9.4.7 Data Channel Segment Composition

The allocated size of a data channel segment is set by segment length (SL) parameter. The segment can be broken down into: TAG slots, AUX slots, DATA slots, and unused slots. The parameters listed in [Table 23-658](#) configure the different lengths.

**Table 23-658. Segment Composition**

Parameter	Register Field	Segment Field	Size Range (slots)	Comments
Segment length	<code>SLIMBUS_DCR_CONFIG1_j[9:5]</code> / <code>SLIMBUS_DCT_CONFIG1_j[9:5]</code> SL	Segment	1 to 31	Encoding 0x0 is reserved.
Transport protocol	<code>SLIMBUS_DCR_CONFIG1_j[3:0]</code> / <code>SLIMBUS_DCT_CONFIG1_j[3:0]</code> TP	TAG	0, 1, 2	N/A
AUX format	<code>SLIMBUS_DCR_CONFIG1_j[19:16]</code> / <code>SLIMBUS_DCT_CONFIG1_j[19:16]</code> AF	AUX	0, 1, 2	N/A
Data length	<code>SLIMBUS_DCR_CONFIG1_j[14:10]</code> / <code>SLIMBUS_DCT_CONFIG1_j[14:10]</code> DL	DATA	0 to 31	Encoding 0x0 is "all remaining slots," don't care if NVB is present
Number of valid bytes	NVB (not in a register field, send in the message)	DATA	0 to 28, even only	Encoded in AUX field, overrides DL, exists only for TP = extended asynchronous

**NOTE:**

- Explicit data length (DL) range is 1 to 31 slots. When encoding 0x0 is used, the DATA field occupies all remaining slots of the segment; that is, not occupied by TAG and AUX. This allows to encode a 0-slot data length.
- NVB is available only in the extended asynchronous transfer protocols (TP), which uses two TAG slots: the maximum remaining length is 31 (SL max) – 2 = 29 slots; that is, the maximum NVB is 14 bytes = 28 slots =< 29 (because NVB is byte-granular and cannot encode odd slot counts)
- Not all combinations are legal. For example, the DATA field of a pushed channel (TP = 0x1: 1 TAG slot) with no AUX information (AF = 0x0) and a 5-slot overall segment length (SL = 0x5) can have only 1 to 4 slots, encoded respectively as DL = 0x1, 0x2, 0x3 and 0x4/0x0.

The SL, TP, AF, and DL setup parameters are received from the appropriate control messages (inside or outside reconfiguration sequences), and programmed into appropriate control registers. They are typically static over long periods.

### 23.9.4.8 SLIMbus Transfer Protocols

Several registers are used to configure each Transfer Protocol. [Table 23-659](#) shows a description of these registers and fields.

**Table 23-659. Register Fields Used to Configure Transfer Protocols**

Register	Field	Description
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [3:0]	TP	Transfer protocol choice
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [4]	TP_QUALIFIER	Used only for asynchronous TPs (qualifier for plain/extended half-duplex asynchronous TPs)
<a href="#">SLIMBUS_DCT_CONFIG1_j</a> [4]	TP_QUALIFIER	Used only for asynchronous TPs (qualifier for plain/extended half-duplex asynchronous TPs)
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [9:5]	SL	Total segment length (SL), in 4-bit slots, $SL \geq TAG\ length + AUX\ length + DATA\ length$
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [26:23]	PR_HI	4-MSB presence rate (PR). Selects the base frequency and the calculation mode of N, with: $PR = 2^N \times base\ frequency$ .
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [22:20]	PR_LO	3-LSB presence rate (PR). Sets the multiple of the base frequency for the presence frequency.
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [14:10]	DL	Segment data length, in 4-bits slots. AUX+DATA length must fit in a FIFO word.
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [15]	CL	N/A
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [31]	ENABLE	Enable/disable data channel
<a href="#">SLIMBUS_DCR_CONFIG2_j / SLIMBUS_DCT_CONFIG2_j</a> [11:0]	SD	Segment periodicity and offset (segment distribution)

#### 23.9.4.8.1 Isochronous Transfer Protocol

[Table 23-660](#) lists the register fields to program isochronous data transfer protocol.

**Table 23-660. Register Fields Used for Isochronous Transfer Protocol**

Register	Field	Value
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [3:0]	TP	0x0 (isochronous transfer protocol)
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [4]	TP_QUALIFIER	Unused in this mode
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [9:5]	SL	2 to 8, see <a href="#">Section 23.9.4.7</a>
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [26:23]	PR_HI	N/A, only for information
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [22:20]	PR_LO	N/A
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [14:10]	DL	2 to 8, see <a href="#">Section 23.9.4.7</a>
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [15]	CL	N/A
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [31]	ENABLE	1 (enabled)
<a href="#">SLIMBUS_DCR_CONFIG2_j / SLIMBUS_DCT_CONFIG2_j</a> [11:0]	SD	Segment periodicity and offset

##### 23.9.4.8.1.1 Isochronous Segment Composition

Like for all other TPs, the TDM allocation of a pushed data channel is composed of periodic segments of equal length, with the 5-bit segment length (SL) defining the reserved length, in slots (1 to 31), and the segment distribution (SD) defining the segmen offset and periodicity.

Isochronous has no explicit presence bit because data is always assumed to be present. The SL-slots segment is therefore always composed of the following elements:

- 0, 1, or 2 AUX slots, as defined by the 4-bit auxiliary format (AF) configuration field
- 2 to 8 DATA slots, as defined by the 5-bit data length (DL) configuration field. Full range defined by standard is 1 to 31.
- 0 or more unused slots (should be 0, because this is wasted bandwidth)

**NOTE:**

- Maximum supported SL and DL are limited by the maximum FIFO word size (the actual implementation of the agent), because each segment (with data present) contains one FIFO word of DATA + AUX. In the current case, FIFO word size is 2 to 8 slots (8 to 32 bits):
  - DL range is 2 to 8 (assuming no AUX slot, or AUX slots stored with the DATA in the FIFO)
  - SL range is 2 to 8 (= DL, since there is no TAG in isochronous protocol).
  - DL = 0 is a special encoding where all slots after the AUX are considered to be DATA slots. In that case, there are by definition no unused slots.
- DL = 0 is a special encoding where all slots after the AUX are considered to be DATA slots. In that case, there are by definition no unused slots.
- Not all combinations of legal field values are legal. The condition is that AUX and DATA slots must fit within the allocated segment, that is, the sum must not be (strictly) greater than SL.
  - DL = 31 cannot be used with 1-slot AUX contents because 1 AUX slot + 31 DATA slots (DL) > 31 segment slots (SL max) (assuming no more FIFO word size limit)
  - DL = 30 cannot be used with 2-slot AUX contents (assuming no more FIFO word size limit)
  - ...

**23.9.4.8.2 Pushed Transfer Protocol**

Table 23-661 lists the register fields to program to have a pushed data transfer protocol.

**Table 23-661. Register Fields Used for Pushed Transfer Protocol**

Register	Field	Value
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[3:0]	TP	0x1 (pushed Transfer Protocol)
SLIMBUS_DCR_CONFIG1_j[4]	TP_QUALIFIER	unused in this mode
SLIMBUS_DCT_CONFIG1_j[4]	TP_QUALIFIER	unused in this mode
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[9:5]	SL	3 to 9, see <a href="#">Section 23.9.4.7</a>
SLIMBUS_DCR_CONFIG1_j[26:23]	PR_HI	N/A, only for information
SLIMBUS_DCR_CONFIG1_j[22:20]	PR_LO	N/A, only for information
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[14:10]	DL	2 to 8, see <a href="#">Section 23.9.4.7</a>
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[15]	CL	N/A
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[31]	ENABLE	1 (enabled)
SLIMBUS_DCR_CONFIG2_j / SLIMBUS_DCT_CONFIG2_j[11:0]	SD	segment periodicity and offset

**23.9.4.8.2.1 Pushed Segment Composition**

Like for all other TPs, the TDM allocation of a pushed data channel is composed of periodic segments of equal length, with the 5-bit segment length (SL) defining the reserved length, in slots (1 to 31), and the segment distribution (SD) defining the segment's offset and periodicity.

When data is present (P=1), the SL-slots segment is composed of the following elements:

- 1 TAG slot for STR, P control bits (Sample TRansmit, Presence)
- 0, 1 or 2 AUX slots, as defined by the 4-bit auxiliary format (AF) configuration field
- 2 to 8 DATA slots, as defined by the 5-bit data length (DL) configuration field. Full range defined by standard is 1 to 30
- 0 or more unused slots. (should be 0, as this is wasted bandwidth)

When no data is present (P=0), all slots except the TAG are unused and undriven.

**NOTE:**

- Maximum supported SL and DL are limited by the maximum FIFO word size (that is, the agent's actual implementation), as each segment (with data present) contains one FIFO word of DATA + AUX. In the current case, FIFO word size is 2 to 8 slots (8 to 32 bits), that is,
  - DL range is 2 to 8 (assuming no AUX slot, or AUX slots stored with the DATA in the FIFO)
  - SL range is 3 to 9 (= DL + 1 TAG)
- DL=0 is a special encoding where all slots after the AUX are considered to be DATA slots. In that case, there are by definition no unused slots.
- Not all combinations of legal field values are legal. The condition is that AUX and DATA slots must fit within the allocated segment, that is, the sum must not be (strictly) greater than SL.
  - DL=31 cannot be used at all for pushed (although it is legal for other TPs) because 1 TAG slot + 31 DATA slots (DL) > 31 segment slots (SL max).
  - DL=30 cannot be used with 1-slot AUX contents (assuming no more FIFO word size limit)
  - DL=29 cannot be used with 2-slot AUX contents (assuming no more FIFO word size limit)
  - ...

**23.9.4.8.3 Pulled Transfer Protocol**

Table 23-662 lists the register fields to program to have a pulled data transfer protocol.

**Table 23-662. Register fields used for Pulled Transfer Protocol**

Register	Field	Value
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [3:0]	TP	0x2 (pulled Transfer Protocol)
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [4]	TP_QUALIFIER	unused in this mode
<a href="#">SLIMBUS_DCT_CONFIG1_j</a> [4]	TP_QUALIFIER	unused in this mode
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [9:5]	SL	3 to 9, see <a href="#">Section 23.9.4.7</a>
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [26:23]	PR_HI	N/A, only for information
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [22:20]	PR_LO	N/A, only for information
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [14:10]	DL	2 to 8, see <a href="#">Section 23.9.4.7</a>
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [15]	CL	N/A
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [31]	ENABLE	1 (enabled)
<a href="#">SLIMBUS_DCR_CONFIG2_j</a> / <a href="#">SLIMBUS_DCT_CONFIG2_j</a> [11:0]	SD	segment periodicity and offset

### 23.9.4.8.3.1 Pulled Segment Composition

Like for all other TPs, the TDM allocation of a pushed data channel is composed of periodic segments of equal length, with the 5-bit segment length (SL) defining the reserved length, in slots (1 to 31), and the segment distribution (SD) defining the segment's offset and periodicity.

When data is present (P=1), the SL-slots segment is composed of the following elements:

- 1 TAG slot for SRQ, P control bits (Sample ReQuest, Presence)
- 0, 1 or 2 AUX slots, as defined by the 4-bit auxiliary format (AF) configuration field
- 2 to 8 DATA slots, as defined by the 5-bit data length (DL) configuration field. Full range defined by standard is 1 to 30.
- 0 or more unused slots. (should be 0, as this is wasted bandwidth)

When no data is present (P=0), all slots except the TAG are unused and undriven.

#### NOTE:

- Maximum supported SL and DL are limited by the maximum FIFO word size (that is, the agent's actual implementation), as each segment (with data present) contains one FIFO word of DATA + AUX. In the current case, FIFO word size is 2 to 8 slots (8 to 32 bits), that is,
  - DL range is 2 to 8 (assuming no AUX slot, or AUX slots stored with the DATA in the FIFO)
  - SL range is 3 to 9 (= DL + 1 TAG)
- DL=0 is a special encoding where all slots after the AUX are considered to be DATA slots. In that case, there are by definition no unused slots.
- Not all combinations of legal field values are legal. The condition is that AUX and DATA slots must fit within the allocated segment, that is, the sum must not be (strictly) greater than SL.
  - DL=31 cannot be used at all for pushed (although it is legal for other TPs) because 1 TAG slot + 31 DATA slots (DL) > 31 segment slots (SL max).
  - DL=30 cannot be used with 1-slot AUX contents (assuming no more FIFO word size limit)
  - DL=29 cannot be used with 2-slot AUX contents (assuming no more FIFO word size limit)
  - ...

### 23.9.4.8.4 Asynchronous Transfer Protocol

Table 23-665 shows the configuration required for a (plain) asynchronous data channel agent, whether in simplex or in half-duplex mode.

One data channel requires one agent, except for 1/2 duplex where 2 agents are required (one in each direction).

**Table 23-663. "Plain" Asynchronous Endpoint Configurations**

Agent Setup	Type	TP	TP_qualifier	SD, SL, DL, ENABLE	Notes
TX simplex	TX	0x4 = "plain" asynchronous, simplex	0b0 = primary owner	independent	always primary owner
TX 1/2 duplex, primary	TX	0x5 = "plain" asynchronous, 1/2 duplex	0b0 = primary owner	same than RX (programming identical in both associated agent)	associated with RX agent
TX 1/2 duplex, secondary	TX	0x5 = "plain" asynchronous, 1/2 duplex	0b1 = secondary owner	same than RX (programming identical in both associated agent)	associated with RX agent

**Table 23-663. "Plain" Asynchronous Endpoint Configurations (continued)**

Agent Setup	Type	TP	TP_qualifier	SD, SL, DL, ENABLE	Notes
RX simplex	RX	0x4 = "plain" asynchronous, simplex	0b1 = secondary owner	independent	always secondary owner
RX 1/2 duplex, primary	RX	0x5 = "plain" asynchronous, 1/2 duplex	0b0 = primary owner	same than TX (programming identical in both associated agent)	associated with TX agent
RX 1/2 duplex secondary	RX	0x5 = "plain" asynchronous, 1/2 duplex	0b1 = secondary owner	same than TX (programming identical in both associated agent)	associated with TX agent

Table 23-666 lists the register fields to program to have a "plain" asynchronous transfer protocol.

**Table 23-664. Register fields used for "Plain" Asynchronous Transfer Protocol**

Register (for a given data channel agent)	Field	Value
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[3:0]	TP	0x4 (simplex) or 0x5 (half duplex)
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[4]	TP_QUALIFIER	primary or secondary ownership setup
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[9:5]	SL	3 to 9, see <a href="#">Section 23.9.4.7</a>
SLIMBUS_DCR_CONFIG1_j[26:23]	PR_HI	Presence Rate, only for information
SLIMBUS_DCR_CONFIG1_j[22:20]	PR_LO	N/A, only for information
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[14:10]	DL	2 to 8, see <a href="#">Section 23.9.4.7</a>
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[15]	CL	0 (disabled: makes no sense in asynchronous context)
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[31]	ENABLE	1 (enabled)
SLIMBUS_DCR_CONFIG2_j / SLIMBUS_DCT_CONFIG2_j[11:0]	SD	segment periodicity and offset

#### 23.9.4.8.4.1 Asynchronous Segment Composition

Like for all other TPs, the TDM allocation of an asynchronous data channel is composed of periodic segments of equal length, with the 5-bit segment length (SL) defining the reserved length, in slots (2 to 31), and the segment distribution (SD) defining the segment's offset and periodicity.

When data is present (P=1), the SL-slots segment is composed of the following elements:

- 1 TAG slot for T1, T2, CTS, P control bits
- 0, 1 or 2 AUX slots, as defined by the 4-bit auxiliary format (AF) configuration field
- 2 to 8 DATA slots, as defined by the 5-bit data length (DL) configuration field. Full range defined by standard is 1 to 30.
- 0 or more unused slots. (should be 0, as this is wasted bandwidth)

When no data is present (P=0), only the TAG slot is (partially) driven, depending on the ownership control and data flow control protocol phases. All other slots are unused and undriven.

**NOTE:**

- Maximum supported SL and DL are limited by the maximum FIFO word size (that is, the agent's actual implementation), as each segment (with data present) contains one FIFO word of DATA + AUX. In the current case, FIFO word size is 2 to 8 slots (8 to 32 bits), that is,
  - DL range is 2 to 8 (assuming no AUX slot, or AUX slots stored with the DATA in the FIFO)
  - SL range is 3 to 9 (= DL + 1 TAG)
- DL=0 is a special encoding where all slots after the AUX are considered to be DATA slots. In that case, there are by definition no unused slots. When used, the actual length of the segment data (in slots) is determined by hardware, by subtracting the TAG and AUX slots from the total segment length (SL). This case is strictly equivalent to the "direct" encoding, that is, where DL is a non-zero figure.
- Not all combinations of legal field values are legal, even in an ideal implementation. The condition is that TAG, AUX and DATA slots must fit within the allocated segment, that is, the sum must not be (strictly) greater than SL.
  - DL=31 cannot be used at all for asynchronous (although it is legal for other TPs) because 1 TAG slot + 31 DATA slots (DL) > 31 segment slots (SL max).
  - DL=30 cannot be used with 1-slot AUX contents (assuming no more FIFO word size limit)
  - DL=29 cannot be used with 2-slot AUX contents (assuming no more FIFO word size limit)
  - SL = 1 is forbidden, since the smallest asynchronous segment is 1 TAG slots + 1 DATA slot = 2 slots long.
  - ...

**23.9.4.8.4.2 Programming Specificities for Half-Duplex Protocol**

Contrary to all other standard transfer protocols (TP), the half-duplex asynchronous ones (plain or extended) are bidirectional, that is, DATA slots can go in both directions. This means that 1 half-duplex asynchronous port (mapped on 1 half-duplex asynchronous data channel) uses 2 unidirectional data channel agents (FIFOs and logic) in the same controller.

The two agents are of opposite directions (1 TX + 1 RX), and the configuration register fields must always be programmed simultaneously and with matching values for both, so that both own the exact same slots (the data channel's allocated distribution).

**23.9.4.8.5 Extended Asynchronous Transfer Protocol**

Table 23-665 shows the configuration required for an extended asynchronous data channel agent, whether in simplex or in half-duplex mode.

One data channel requires one agent, except for 1/2 duplex where 2 agents are required (one in each direction).

**Table 23-665. Extended Asynchronous Endpoint Configurations**

Agent Setup	Type	TP	TP_qualifier	SD, SL, DL, ENABLE	Notes
TX simplex	TX	0x6 = extended asynchronous, simplex	0b0 = primary owner	independent	always primary owner
TX 1/2 duplex, primary	TX	0x7 = extended asynchronous, 1/2 duplex	0b0 = primary owner	same than RX (programming identical in both associated agent)	associated with RX agent

**Table 23-665. Extended Asynchronous Endpoint Configurations (continued)**

Agent Setup	Type	TP	TP_qualifier	SD, SL, DL, ENABLE	Notes
TX 1/2 duplex, secondary	TX	0x7 = extended asynchronous, 1/2 duplex	0b1 = secondary owner	same than RX (programming identical in both associated agent)	associated with RX agent
RX simplex	RX	0x6 = extended asynchronous, simplex	0b1 = secondary owner	independent	always secondary owner
RX 1/2 duplex, primary	RX	0x7 = extended asynchronous, 1/2 duplex	0b0 = primary owner	same than TX (programming identical in both associated agent)	associated with TX agent
RX 1/2 duplex secondary	RX	0x7 = extended asynchronous, 1/2 duplex	0b1 = secondary owner	same than TX (programming identical in both associated agent)	associated with TX agent

The data length within the segment is now determined in the TAG NVB field, so that the SLIMbus data length (DL) parameter is not needed in the SLIMbus definition. The corresponding configuration register field [SLIMBUS\\_DCR\\_CONFIG1\\_j](#) / [SLIMBUS\\_DCT\\_CONFIG1\\_j](#)[14:10] DL is still needed to set the FIFO word size: it must always be programmed to 0x2 (slots) = 1 byte, in both the data sinks and sources, which corresponds to the NVB granularity unit.

[Table 23-666](#) lists the register fields to program to have a "plain" asynchronous transfer protocol.

**Table 23-666. Register fields used for Extended Asynchronous Transfer Protocol**

Register (for a given data channel agent)	Field	Value
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [3:0]	TP	0x6 (simplex) or 0x7 (half duplex)
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [4]	TP_QUALIFIER	primary or secondary ownership setup
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [9:5]	SL	4 to 31, see <a href="#">Section 23.9.4.7</a>
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [26:23]	PR_HI	Presence Rate, only for information
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [22:20]	PR_LO	N/A, only for information
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [14:10]	DL	2: NVB data granularity (not the Slimbus "data length")
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [15]	CL	0 (disabled: makes no sense in asynchronous context)
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [31]	ENABLE	1 (enabled)
<a href="#">SLIMBUS_DCR_CONFIG2_j</a> / <a href="#">SLIMBUS_DCT_CONFIG2_j</a> [11:0]	SD	segment periodicity and offset

### 23.9.4.8.5.1 Extended Asynchronous Segment Composition

Like for all other TPs, the TDM allocation of an extended asynchronous data channel is composed of periodic segments of equal length, with the 5-bit segment length (SL) defining the reserved length, in slots (1 to 31), and the segment distribution (SD) defining the segment's offset and periodicity.

When data is present (P=1), the segment is composed of the following elements:

- 2 TAG slots for T1, T2, CTS, P control bits + 4-bit NVB field
- no (0) AUX slots. The current implementation does not support auxiliary fields in the extended asynchronous TP, that is, the only legal value in the 4-bit auxiliary format (AF) is 0b0000. Other values are theoretically allowed by the SLIMbus standard, but for this TP they have little functional use.
- 0 to 28 DATA slots, as defined by the 4-bit number of valid bytes (NVB) field
- 0 or more unused slots. (this is wasted bandwidth, but as NVB can change for each segment this is

normal)

When no data is present (P=0):

- 1st TAG slot is (partially) driven, depending on the ownership / data flow control protocol phases.
- 2nd TAG slot is either driven to all-zero, or undriven, that is, it always reads out as all-zero.
- All other slots are unused and undriven

---

**NOTE:**

- SL should be configured so that the maximum number of DATA slots is even, otherwise there will always be at least one unused slot.
  - Largest supported SL is not limited by the maximum FIFO word size (that is, the agent's actual implementation), unlike all other transfer protocols, as several FIFO words can be concatenated inside the same data segment.
  - Not all combinations of legal field values are legal. The condition is that TAG, AUX and DATA slots must fit within the allocated segment, that is, the sum must not be (strictly) greater than SL.
    - NVB = 15 (15 valid data bytes = 30 slots) cannot be used, because 2 TAG slots + 30 DATA slots (NVB x 2) = 32 > 31 segment slots (SL max).
    - SL = 1,2,3 are forbidden, since the smallest extended asynchronous segment is 2 TAG slots + 1 DATA byte (NVB = 1) = 4 slots long.
    - ...
- 

#### 23.9.4.8.5.2 Programming Specificities for Half-Duplex Protocol

Contrary to all other standard transfer protocols (TP), the half-duplex asynchronous ones (plain or extended) are bidirectional, that is, DATA slots can go in both directions. This means that 1 half-duplex asynchronous port (mapped on 1 half-duplex asynchronous data channel) uses 2 unidirectional data channel agents (FIFOs and logic) in the same controller.

The two agents are of opposite directions (1 TX + 1 RX), and the configuration register fields must always be programmed simultaneously and with matching values for both, so that both own the exact same slots (the data channel's allocated distribution).

#### 23.9.4.9 Paired-up channels

Two (or more) data channels with common properties can be paired up to operate in lockstep, like e.g. the left and right channels of a stereo audio flow: paired up data samples are generated together by a data source and need to arrive together at the data sink after going over the SLIMbus interface.

Assuming that pairing up has been implemented in both the sink and the source SLIMbus controllers of the data channel, it is enabled by configuring the channel as follows:

- Same segment windows: same channel rate, also expressed as segment interval (expressed in slots). This is encoded in the channel's Segment Distribution ([SLIMBUS\\_DCT\\_CONFIG2\\_j](#) / [SLIMBUS\\_DCR\\_CONFIG2\\_j](#)[11:0] SD).
- Same Segment Length ([SLIMBUS\\_DCT\\_CONFIG1\\_j](#) / [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[9:5] SL)
- Segment offset (also encoded in SD) is necessarily different, otherwise the two channels would be scheduled in the same slots. SD is therefore different.
- Sequential Channel Numbers (CN) are assigned to the channels to be paired up
- Data channel numbering and scheduling are defined by the active manager device, through the broadcasts of the NEXT\_DEFINE\_CHANNEL() message.

Contents must be aligned, as follows:

- Same Transfer Protocol ([SLIMBUS\\_DCT\\_CONFIG1\\_j](#) / [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[3:0] TP). Asynchronous protocols (extended or not) do not support pairing.
- Same Aux Format ([SLIMBUS\\_DCT\\_CONFIG1\\_j](#) / [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[19:16] AF)
- Same Data Length ([SLIMBUS\\_DCT\\_CONFIG1\\_j](#) / [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[14:10] DL)
- Pairing can be enabled through the Channel Link ([SLIMBUS\\_DCT\\_CONFIG1\\_j](#) /

SLIMBUS\_DCR\_CONFIG1\_j[15] CL) data channel content bit. Pairing between channel #N-1 and channel #N is enabled by setting the Channel Link (CL) content bit to 1 on channel #N. For example, to pair up channels #1 and #2, CL = 1 in channel #2 (thus linking it to #1) and CL = 0 in channel #1 (thus keeping it separate from channel #0).

- Data channel contents are defined by active manager device, through the broadcasting of the NEXT\_DEFINE\_CONTENT() and CHANGE\_CONTENT() messages.

#### 23.9.4.9.1 Paired-up behaviour for Isochronous TP

Data is by definition present in all segments, so that isochronous data channels with the same channel rate (as extracted from SD) are naturally paired up in normal operation. However, pairing also ensures that transmit underflows are also coupled:

- On the source side, if one of the channels has no data to transmit (TX underflow error, reported by IRQ) the other channels won't transmit any data either (even if they have some). This prevents the transmitter from getting out of sync.
- On the sink side, the underflow error will not be detected since no presence indication is transmitted, but the channels will remain in sync when the correct data flow resumes.

#### 23.9.4.9.2 Paired-up behaviour for Pushed TP

Data presence in each segment is flagged by the STR/P bits (strobe/presence) driven by the data source in the TAG slot. On the source side, paired up channels must have the same P value in a given segment window, that is, data must only be transmitted (STR=P=1) when both channels have data to send. No requirements on the sink side.

#### 23.9.4.9.3 Paired-up behaviour for Pulled TP

Data presence in a segment is requested by the SRQ TAG bit (sample request), driven by the sink, and confirmed by the P TAG bit (presence), driven by the source, so that SRQ and P are always equal in normal operation. The main pairing up requirement is therefore that the SRQ are aligned for all channel sinks, that is, that data is requested on all channels only if all sinks are ready to receive it, otherwise it is requested on none.

Pairing also ensures that transmit underflows are also coupled between channels: if for some reason a source cannot fulfill a request to drive data (SRQ=1, P=0: transmit underflow error, reported by IRQ), none of the other channels must drive data either, and all must flag P=0. The source side can only implement correct pairing if the sink side is correct in the first place; indeed, unless an underflow occurs, it is sufficient that the sink side implements pairing for the channels to be paired.

#### 23.9.4.10 Device and Addressing Management

One of the manager device tasks is to keep track of devices present on the bus and to enumerate them, that is, assign a (different) Logical Address (LA) to each.

The manager device itself is implicitly enumerated by default, to Logical Address (LA) 0xFF. This is the only case where a device enumerates without ASSIGN\_LOGICAL\_ADDRESS message transmitted over the bus. Therefore for the manager device the following default configuration must be applied :

- SLIMBUS\_DEV\_LA\_i[7:0] LA = 0xFF
- SLIMBUS\_DEV\_LA\_i[8] LA\_ENABLE = 1
- SLIMBUS\_DEV\_LA\_i[9] EA\_ENABLE = 1 (although manager is never addressed by Enumeration Address, EA)

The SLIMbus controller implements several devices, each of which is identified by its address. Addresses are used to exchange control messages over the shared message channel (SMC). The controller will recognize, store and respond (e.g. acknowledge) to any message on the SMC targeted at one of the component's devices in the RX message FIFO.

The Enumeration Addresses (EA) composition is described in [Table 23-667](#), with:

- MI, PC and IV are Software-programmable and have the same value for all devices of the component with SLIMBUS\_CMP\_MI\_PC[15:0] MI, SLIMBUS\_CMP\_MI\_PC[31:16] PC and SLIMBUS\_CMP\_IV[7:0] IV.

- DI is hardwired and unique for each device within the component. It is given by [SLIMBUS\\_DCT\\_MAP\\_j](#) / [SLIMBUS\\_DCR\\_MAP\\_j](#)[7:0] DI bit field.
- Each device individual EA is Software-accessible, for reference, in read-only registers ([SLIMBUS\\_DEV\\_EA\\_LO\\_i](#) and [SLIMBUS\\_DEV\\_EA\\_HI\\_i](#) registers)

**Table 23-667. Enumeration Address (EA) makeup**

EA Subfield	Size (bits)	Top Bit	Bottom Bit	Source
MI: Manufacturer ID	16	47	32	<a href="#">SLIMBUS_CMP_MI_PC</a> [15:0] MI
PC: Product Code	16	31	16	<a href="#">SLIMBUS_CMP_MI_PC</a> [31:16] PC
DI: Device Index	8	15	8	hardwired
IV: Instance Value	8	7	0	<a href="#">SLIMBUS_CMP_IV</a> [7:0] IV
Total: EA	48	47	0	<a href="#">SLIMBUS_DEV_EA_HI_i</a> / <a href="#">SLIMBUS_DEV_EA_LO_i</a>

The Logical Address (LA) assigned by the manager range from 0x00 to 0xEF, with the exception of the active manager located by definition at LA = 0xFF. It is configured through [SLIMBUS\\_DEV\\_LA\\_i](#)[7:0] LA for device m.

By default, a device uses a unique, static 48-bit Enumeration Address (EA). The EA is used only for enumeration, that is, the acquisition a dynamic Logical Address (LA) assigned by the active manager device.

---

**NOTE:** The port number is given by [SLIMBUS\\_DCT\\_MAP\\_j](#) / [SLIMBUS\\_DCR\\_MAP\\_j](#)[13:8] PN bit field.

---

### 23.9.4.11 Message Management

#### 23.9.4.11.1 Transmission

##### 23.9.4.11.1.1 TX Message Sequence

The message transmission software sequence is the following:

- Initial state:
  - [SLIMBUS\\_SMT\\_CONTROL](#)[0] MESSAGE\_ENABLE = 0: No ongoing TX message. This also implies that TX message FIFO can receive another message.
  - [SLIMBUS\\_SMT\\_INFO](#)[5:0] = 0 : TX message event flags must be cleared (to 0) by Software by writing 1 to the corresponding bit(s). Failing to meet this condition will not prevent the message transmission, but will prevent a proper readout of the message transmission's outcome
  - Optional: If the IRQ method is to be used (instead of polling), it must be cleared and enabled, that is, [SLIMBUS\\_CMP\\_IRQENABLE\\_SET](#)[2] SMT\_INFO\_EN = 1 and [SLIMBUS\\_CMP\\_IRQSTATUS](#)[2] SMT\_INFO = 0. For more information about interrupts see [Section 23.9.4.12](#)
- FIFO loading:
  - The message is written byte by byte to register [SLIMBUS\\_SMT\\_MESSAGE](#)[7:0]. SLIMbus endianness is retained (big-endian) that is, serial message starts with the MSB (bit 7) of the first byte written into the FIFO and ends with the LSB (bit 0) of the last written byte.
  - The minimum message size is 6 bytes (5 entered to the FIFO), for a short-arbitration (that is, logical source address [SLIMBUS\\_DEV\\_LA\\_i](#)[7:0] LA = 1 byte), broadcast (that is, no destination address), no-payload message.
  - The maximum theoretical message size is 39 bytes (38 entered to the FIFO), for a long-arbitration (that is, enumeration source address EA = 6 bytes), maximum remaining length (RL = 5b11111 = 31 bytes) message. The TX message FIFO can hold 32 bytes, that is, most messages (of 33 bytes or less).
  - An overflow event is flagged ([SLIMBUS\\_SMT\\_INFO](#)[1] OVERFLOW is set) if too many bytes are written in. The TX message FIFO is then cleared before another TX message sequence attempt is made.

- Transmission enabling:
  - Once the message has been loaded into the TX message FIFO, software must write 1 on field [SLIMBUS\\_SMT\\_CONTROL\[0\] MESSAGE\\_ENABLE](#).
- Transmission:
  - From that point on, the device will attempt to transmit the message stored in the FIFO. Actual transmission may be delayed because of Message Sync acquisition time (if not already operational), Ongoing message on the SMC, and Arbitration(s) lost to higher-priority messages.
- Transmission completion and reporting:
  - Transmission is considered complete if one of the following -mutually exclusive- conditions is met, and the corresponding bit of [SLIMBUS\\_SMT\\_INFO](#) is set : Negative response [SLIMBUS\\_SMT\\_INFO\[3\] NACK = 1](#), or Positive response : [SLIMBUS\\_SMT\\_INFO\[2\] PACK = 1](#), or No response: [SLIMBUS\\_SMT\\_INFO\[4\] NORE = 1](#), or Illegal response: [SLIMBUS\\_SMT\\_INFO\[5\] UDEF = 1](#), or Transmit collision: [SLIMBUS\\_SMT\\_INFO\[0\] MC\\_TX\\_COL = 1](#).
  - If enabled ([SLIMBUS\\_CMP\\_IRQENABLE\\_SET\[2\] SMT\\_INFO\\_EN = 1](#)), an interrupt request flag is set ([SLIMBUS\\_CMP\\_IRQSTATUS\[2\] SMT\\_INFO = 1](#)) and the IRQ line asserted.
  - Additionally, bit [SLIMBUS\\_SMT\\_CONTROL\[0\] MESSAGE\\_ENABLE](#) must auto-clear. Polling this bit will also work as an alternative to waiting for the IRQ.
  - Following the transmission, all message bytes have been removed from the TX message FIFO.

#### **23.9.4.11.1.2 TX Message FIFO Clearing**

The TX message FIFO must not be cleared as part of the normal message transmission operation, between messages. However, the clearing becomes necessary in case of error:

- FIFO overflow: the bit [SLIMBUS\\_SMT\\_INFO\[1\] OVERFLOW](#) is set
- FIFO underflow: the bit [SLIMBUS\\_SMR\\_INFO\[1\] UNDERFLOW](#) is set
- TX collision: the bit [SLIMBUS\\_SMT\\_INFO\[0\] MC\\_TX\\_COL](#) or the bit [SLIMBUS\\_SMR\\_INFO\[0\] MC\\_TX\\_COL](#) is set
- Undefined error condition, unknown FIFO content

Clearing is done by writing 0 to bit field [SLIMBUS\\_SMT\\_CONTROL\[0\] MESSAGE\\_ENABLE](#).

#### **23.9.4.11.2 Message reception**

##### **23.9.4.11.2.1 Message Responding**

The message responding and message receiving are separate but intertwined processes. Message responding starts as soon as a message is received, and consists in sending back information, including PACK or NACK.

##### **23.9.4.11.2.2 RX Message Sequence**

The message reception software sequence is the following:

- Initial state
  - [SLIMBUS\\_SMR\\_INFO = 0x0](#): Pending (at 1) RX message event flags must be cleared (to 0) by Software by writing 1 to the corresponding bit(s).
  - Optional: If the IRQ method is to be used (instead of polling), it must be cleared and enabled, that is, [SLIMBUS\\_CMP\\_IRQENABLE\\_SET\[3\] SMR\\_INFO\\_EN = 1](#) and [SLIMBUS\\_CMP\\_IRQSTATUS\[3\] SMR\\_INFO = 0](#). For more information about interrupts see [Section 23.9.4.12](#)
- Message reception
  - Message reception requires no intervention: Messages with target addresses enabled in [SLIMBUS\\_DEV\\_LA\\_i](#) registers are automatically loaded into the RX message FIFO.
- FIFO unloading
  - The message is read byte by byte off the FIFO and put into register [SLIMBUS\\_SMR\\_MESSAGE\[7:0\]](#). SLIMbus endianness is used (big-endian) that is, serial message starts with the MSB (bit 7) of the first byte written into the FIFO and ends with the LSB (bit 0) of the last written byte.

- The minimum message size is 6 bytes, for a short-arbitration (that is, logical source address LA = 1 byte), broadcast (that is, no destination address), no-payload message.
- The maximum theoretical message size is 39 bytes, for a long-arbitration (that is, enumeration source address EA = 6 bytes), maximum remaining length (RL = 5b11111 = 31 bytes) message. The RX message FIFO can hold 32 bytes, that is, most message types.
- An overflow event is flagged ([SLIMBUS\\_SMR\\_INFO\[1\] OVERFLOW](#) bit is set) if too many bytes are received, which will overwrite previous bytes.
- An underflow event is flagged ([SLIMBUS\\_SMR\\_INFO\[1\] UNDERFLOW](#) bit is set) if too many bytes are read out. The RX message FIFO is cleared before another RX message sequence attempt is made.
- Message decoding and servicing
  - This phase takes place in parallel with the unloading phase above. In some cases, a partial decoding can lead the software to skip the end of the unloading and flush the FIFO. The software will check Device Association (thanks to the [SLIMBUS\\_SMR\\_INFO\[2\] RECEIVED\\_MESSAGE](#) bit) and Message Support.

#### 23.9.4.11.2.3 RX Message FIFO Clearing

- While the software is reading the message off the FIFO, the receive message agent unconditionally answers NACK, forcing remote side to retransmit any new incoming message.
- Only once the message has been read out of the FIFO, the software writes 1 on [SLIMBUS\\_SMR\\_INFO\[2\] RECEIVED\\_MESSAGE](#) bit. This will automatically clear the FIFO.

The RX message FIFO is cleared as part of the normal message reception operation, between messages, although it is not strictly necessary. However, the clearing becomes compulsory in case of error:

- FIFO overflow: the bit [SLIMBUS\\_SMT\\_INFO\[1\] OVERFLOW](#) is set
- FIFO underflow: the bit [SLIMBUS\\_SMR\\_INFO\[1\] UNDERFLOW](#) is set
- Undefined error condition, unknown FIFO content

Clearing is done by writing 1 to register bit field [SLIMBUS\\_SMR\\_INFO\[2\] RECEIVED\\_MESSAGE](#) bit.

#### 23.9.4.12 Interrupt Service Routines

This section lists specific software programming sequences, to be applied at specific phases of the SLIMbus protocol. This section covers the low-level software service of IRQs. More information about interrupts in the device can be found in [Chapter 17, Interrupt Controllers](#).

The SLIMbus controller has a single IRQ output line, controlled through 9-bit registers [SLIMBUS\\_CMP\\_IRQSTATUS](#), [SLIMBUS\\_CMP\\_IRQENABLE\\_SET](#) and [SLIMBUS\\_CMP\\_IRQENABLE\\_CLR](#). Each bit of this 1st level IRQ management points to a 2nd level information register. There are thus 9 such information registers, each connected with a specific submodule (framer device, interface device, message receiver, message transmitter, and one per generic data device).

2nd level information register and status register are written independently each other. When an event occurs, both bits are set to 1, and when the software writes 1 on either register the corresponding bit is cleared to 0. IRQ line is the status register output.

- When an event takes place, the corresponding 2nd level information bit must be set to 1 (if already 1: no change)
- When an event takes place, the corresponding 1st level IRQ status bit must be set to 1 (if enabled and if not already 1) and trigger an interrupt (if not already active). Note that this does not depend on the information bit's value: if the information bit is already high, the event must still potentially set the IRQ status bit.
- Writing 1 to a set IRQ status bit clears the bit and deasserts the IRQ line (if another status bit is set, the IRQ line will reassert immediately). Note that the clearing of the IRQ status does not depend on the information bit, that is, it will work even if the information bit has not been cleared.
- Writing 1 to a set information bit will clear the bit, but have no impact on the IRQ status

**CAUTION**

The software sequence should always be as follows:

1. Clear the status bit
2. Read the relative information register
3. When needed and allowed, clear the information register

**23.9.4.12.1 Interrupt Requests**

Table 23-668 lists the event flags, and their mask, that can cause module interrupts.

**Table 23-668. Events**

Interrupt Line	Event Flag	Event Mask
SLIMBUS1_IRQ / SLIMBUS2_IRQ	SLIMBUS_CMP_IRQSTATUS_RAW[11:0] and SLIMBUS_CMP_IRQSTATUS[11:0]	SLIMBUS_CMP_IRQENABLE_SET[11:0] and SLIMBUS_CMP_IRQENABLE_CLR[11:0]

**23.9.4.12.2 Possible Interrupts**

Table 23-669 lists all the interrupts that can occur and the related registers.

**Table 23-669. Interrupts summary**

Interrupt	Register	Field name	Description
Transmit collision in data channel port	SLIMBUS_DCT_INFO_j[0]	DATA_TX_COL	TX collision in TX data channel agent
Data segment overlap	SLIMBUS_FL_INFO[4]	DATA_SLOT_OVERLAP	Overlap detected between a data segment and either the control space or another segment.
Lost message synchronization	SLIMBUS_FL_INFO[2]	LOST_MS	Message Synchronization lost
Lost superframe synchronization	SLIMBUS_FL_INFO[1]	LOST_SFS	Super Frame Synchronization lost
Lost frame synchronization	SLIMBUS_FL_INFO[0]	LOST_FS	Frame Synchronization lost
Transmit collision in message body, Transmit collision in message response	SLIMBUS_SMT_INFO[0]	MC_TX_COL	Transmit collision in Message Channel during message transmission.
Transmit collision in guide channel	SLIMBUS_FR_INFO[2]	GC_TX_COL	Collision during guide byte transmit
Transmit collision in frame sync symbol	SLIMBUS_FR_INFO[1]	FI_TX_COL	Collision during Framing Information transmit
Transmit collision in frame sync symbol	SLIMBUS_FR_INFO[0]	FS_TX_COL	Collision during Frame Sync symbol transmit
Framer device un-activated	SLIMBUS_FR_INFO[4]	FRAMER_UNACTIVATED	Set on ACTIVE_FRAMER information element deassertion
Framer device activated	SLIMBUS_FR_INFO[3]	FRAMER_ACTIVATED	Set on ACTIVE_FRAMER information element assertion
Reconfigured	SLIMBUS_FL_INFO[6]	RECONFIGURED	Reconfiguration boundary crossed
Restart after clock pause	SLIMBUS_FR_INFO[5]	CLOCK_RESTART	Clock restart request event detected
TX message FIFO overflow	SLIMBUS_SMT_INFO[1]	OVERFLOW	Overflow in TX message FIFO
Received positive acknowledge message response	SLIMBUS_SMT_INFO[2]	PACK	TX message was PACK: all recipient devices accepted the message.

**Table 23-669. Interrupts summary (continued)**

Interrupt	Register	Field name	Description
Received negative acknowledge message response	<a href="#">SLIMBUS_SMT_INFO</a> [3]	NACK	TX message was NACK: at least one of the recipient devices requested message retransmission.
Received no message response	<a href="#">SLIMBUS_SMT_INFO</a> [4]	NORE	TX message was NORE: no or all-zero message response
Received undefined message response	<a href="#">SLIMBUS_SMT_INFO</a> [5]	UDEF	TX message was UDEF: undefined response, protocol error.
RX message FIFO underflow	<a href="#">SLIMBUS_SMR_INFO</a> [1]	UNDERFLOW	Underflow in RX message FIFO
Message received	<a href="#">SLIMBUS_SMR_INFO</a> [2]	RECEIVED_MESSAGE	Message available in the RX message FIFO. Clear bit to clear the FIFO and allow the reception of further messages.
Reconfigure_now message received	<a href="#">SLIMBUS_SMR_INFO</a> [3]	RECEIVED_RECONFIGURE	RECONFIGURE_NOW message received, available in RX message FIFO.
Data channel FIFO overflow	<a href="#">SLIMBUS_DCT_INFO_j</a> [1], <a href="#">SLIMBUS_DCR_INFO_j</a> [1]	OVERFLOW	Overflow in TX data channel agent FIFO.
Data channel FIFO underflow	<a href="#">SLIMBUS_DCT_INFO_j</a> [2], <a href="#">SLIMBUS_DCR_INFO_j</a> [2]	UNDERFLOW	Underflow in TX data channel agent FIFO.

### 23.9.4.12.3 Interface Device ISRs

The Interface Device ISRs are applied when a bit of status register [SLIMBUS\\_FL\\_INFO](#) is set, which also triggers the assertion of bit field [SLIMBUS\\_CMP\\_IRQSTATUS](#)[0] FL\_INFO and of the IRQ line, when enabled in bit field [SLIMBUS\\_CMP\\_IRQENABLE\\_SET](#)[0] FL\_INFO\_EN. Service routines must be applied and the FL\_INFO bit field cleared (by writing 1 to it).

#### 23.9.4.12.3.1 Lost frame synchronization (LOST\_FS)

##### 23.9.4.12.3.1.1 Root Event

This interrupt occurs when a loss of frame synchronization happens. All data channels automatically stop, that is, all active [SLIMBUS\\_DCT\\_CONFIG1\\_j](#) / [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[31] ENABLE bits are cleared. Component automatically reacquires frame, superframe and message synchronization.

##### 23.9.4.12.3.1.2 Interrupt Service Routine

Frame synchronization (FS) loss implies the loss of higher-level superframe and message synchronizations:

- Messages cannot be expected to be transmitted / received until the component is operational again. Additionally, any ongoing reconfiguration sequence must be interrupted and made invalid by MS loss. No action required if no reconfiguration sequence is ongoing.
- Implicit superframe synchronization loss triggers a reset of all component ports: see [Section 23.9.4.4.3.6](#).

This field, [SLIMBUS\\_FL\\_INFO](#)[0] LOST\_FS, is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST\_CLEAR\_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

### **23.9.4.12.3.2 Lost superframe synchronization (LOST\_SFS)**

#### **23.9.4.12.3.2.1 Root Event**

This interrupt occurs when a loss of superframe synchronization happens. The loss of lower-level frame synchronization also implies the loss of superframe synchronization, if already acquired, but does not trigger the assertion of LOST\_SFS Information Element. All data channels automatically stop, that is, all active [SLIMBUS\\_DCT\\_CONFIG1\\_j](#) / [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[31] ENABLE bits must be cleared. Component automatically reacquires superframe and message synchronization.

#### **23.9.4.12.3.2.2 Interrupt Service Routine**

Superframe synchronization (SFS) loss will trigger the reset of all ports of the component: see [Section 23.9.4.4.3.6](#).

Superframe synchronization loss implies the loss of message synchronization, that is, messages cannot be expected to be transmitted / received until the component is operational again. Additionally, any ongoing reconfiguration sequence must be interrupted and made invalid by MS loss. No action required if no reconfiguration sequence is ongoing.

This field, [SLIMBUS\\_FL\\_INFO](#)[1] LOST\_SFS, is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST\_CLEAR\_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

### **23.9.4.12.3.3 Lost message synchronization (LOST\_MS)**

#### **23.9.4.12.3.3.1 Root Event**

This interrupt occurs when a loss of message synchronization happens. The loss of either lower-level frame or superframe synchronization also implies the loss of message synchronization, if already acquired, but does not trigger the assertion of LOST\_MS Information Element. Component automatically reacquires message synchronization, by seeking for Guide Channel information.

#### **23.9.4.12.3.3.2 Interrupt Service Routine**

Any ongoing reconfiguration sequence must be interrupted and made invalid by the Message Synchronisation (MS) loss. No action required here if no reconfiguration sequence is ongoing.

This field, [SLIMBUS\\_FL\\_INFO](#)[2] LOST\_MS, is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST\_CLEAR\_INFORMATION message by the remote manager, requiring to clear it (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

### **23.9.4.12.3.4 Found message synchronization (FOUND\_MS)**

#### **23.9.4.12.3.4.1 Root Event**

This interrupt occurs when acquisition of message synchronization. In that state, messages may be transmitted and received over the SMC.

#### **23.9.4.12.3.4.2 Interrupt Service Routine**

If MS is reacquired, following a previous LOST\_MS event, then a REPORT\_INFORMATION message must be transmitted, as follows:

- Source: interface device
- Destination: SLIMbus manager device ([SLIMBUS\\_DEV\\_LA\\_i](#))
- Information Element: [SLIMBUS\\_FL\\_INFO](#)[2] LOST\_MS.

If MS is reacquired, following a previous LOST\_FS event, then a REPORT\_INFORMATION message must be transmitted, as follows:

- Source: interface device
- Destination: SLIMbus manager device (`SLIMBUS_DEV_LA_i[7:0]` LA = 0xFF)
- Information Element: `SLIMBUS_FL_INFO[2]` LOST\_FS.

If MS is reacquired, following a previous LOST\_SFS event, then a REPORT\_INFORMATION message must be transmitted, as follows:

- Source: interface device
- Destination: SLIMbus manager device (`SLIMBUS_DEV_LA_i[7:0]` LA = 0xFF)
- Information Element: `SLIMBUS_FL_INFO[2]` LOST\_SFS.

If MS is reacquired, following a previous MC\_TX\_COL event, then a REPORT\_INFORMATION message must be transmitted, as follows:

- Source: interface device
- Destination: SLIMbus manager device (`SLIMBUS_DEV_LA_i[7:0]` LA = 0xFF)
- Information Element: `SLIMBUS_SMT_INFO[0]` MC\_TX\_COL, `SLIMBUS_SMR_INFO[0]` MC\_TX\_COL.

If MS is reacquired, following a previous UDEF (Received undefined message response) event, the message that caused UDEF must be retransmitted until it succeeds or until the retransmit maximum (fully managed by software) is reached.

In any case, software must clear the field `SLIMBUS_FL_INFO[3]` FOUND\_MS. From that point on, any pending messages in the TX FIFO will be sent.

### 23.9.4.12.3.5 Data segment overlap (DATA\_SLOT\_OVERLAP)

#### 23.9.4.12.3.5.1 Root Event

This interrupt occurs when an internal conflict detected between several data channels or between a data channel and the control space, resulting from an incorrect scheduling (incorrect SD, SL for a given M). Note that no actual collision takes place on the bus.

#### 23.9.4.12.3.5.2 Interrupt Service Routine

A REPORT\_INFORMATION message must be transmitted, as follows:

- Sender: interface device
- Destination: SLIMbus manager device (`SLIMBUS_DEV_LA_i[7:0]` LA = 0xFF)
- Information Element: `SLIMBUS_FL_INFO[4]` DATA\_SLOT\_OVERLAP.

### 23.9.4.12.3.6 Reconfigured (RECONFIGURED)

#### 23.9.4.12.3.6.1 Root Event

This interrupt occurs when crossing of a reconfiguration boundary. In case of clock pause, where the SLIMbus clock stops at the boundary (1st rising edge of the new superframe), the bit (and therefore the IRQ) is asserted at the clock pause, not at the clock restart.

#### 23.9.4.12.3.6.2 Interrupt Service Routine

Completes the software-controller reconfiguration sequence. No reconfiguration must be applied to the control registers between the RECONFIGURE\_NOW reception and the reconfiguration boundary. A attempt by the manager to start a new reconfiguration sequence during that interval is an error.

In the case of framer release handover and/or root frequency change, the active framer must start using a new clock input selection at the reconfiguration boundary (as per register field `SLIMBUS_FR_CLOCK_SOURCE[5:3]` CLKSEL). All non-selected SLIMbus clock inputs of active framer components and all SLIMbus clock inputs for clock receiver components (inactive framers), and that may have been used until the boundary, can be turned off at that point.

Field [SLIMBUS\\_FL\\_INFO\[6\]](#) RECONFIGURED must be software cleared (by writing 1 to it).

#### **23.9.4.12.4 Framer Device ISRs**

The Framer Device ISRs are applied when a bit of status register FR\_INFO is set, which also triggers the assertion of bit field [SLIMBUS\\_CMP\\_IRQSTATUS\[1\]](#) FR\_INFO and of the IRQ line, when enabled in bit field [SLIMBUS\\_CMP\\_IRQENABLE\\_SET\[1\]](#) FR\_INFO\_EN. Service routines must be applied, and the fr\_info bit field cleared (by writing 1 to it). Some interrupt generating events are collisions, which occur when the framer detects on DATA line a different value than it's actively driving.

##### **23.9.4.12.4.1 Transmit collision in frame sync symbol (FS\_TX\_COL)**

###### **23.9.4.12.4.1.1 Root Event**

Transmit collision detected while driving the frame sync symbol (as active framer) of the framing channel.

###### **23.9.4.12.4.1.2 Interrupt Service Routine**

A REPORT\_INFORMATION message must be transmitted, as follows:

- Sender: framer device
- Destination: SLIMbus manager device ([SLIMBUS\\_DEV\\_LA\\_i\[7:0\]](#) LA = 0xFF)
- Information Element: [SLIMBUS\\_FR\\_INFO\[0\]](#) FS\_TX\_COL.

This field is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST\_CLEAR\_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

##### **23.9.4.12.4.2 Transmit collision in frame sync symbol (FI\_TX\_COL)**

###### **23.9.4.12.4.2.1 Root Event**

Transmit collision detected while driving the framing information (as active framer) of the framing channel.

###### **23.9.4.12.4.2.2 Interrupt Service Routine**

A REPORT\_INFORMATION message must be transmitted, as follows:

- Sender: framer device
- Destination: SLIMbus manager device ([SLIMBUS\\_DEV\\_LA\\_i\[7:0\]](#) LA = 0xFF)
- Information Element: [SLIMBUS\\_FR\\_INFO\[1\]](#) FI\_TX\_COL.

This field is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST\_CLEAR\_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

##### **23.9.4.12.4.3 Transmit collision in guide channel (GC\_TX\_COL)**

###### **23.9.4.12.4.3.1 Root Event**

Transmit collision detected while driving the guide byte (as active framer), that is, during the guide channel.

###### **23.9.4.12.4.3.2 Interrupt Service Routine**

A REPORT\_INFORMATION message must be transmitted, as follows:

- Sender: framer device
- Destination: SLIMbus manager device ([SLIMBUS\\_DEV\\_LA\\_i\[7:0\]](#) LA = 0xFF)

- Information Element: [SLIMBUS\\_FR\\_INFO](#)[2] GC\_TX\_COL.

This field is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST\_CLEAR\_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

#### **23.9.4.12.4.4 Framer device activated (FRAMER\_ACTIVATED)**

##### **23.9.4.12.4.4.1 Root Event**

Acquisition of active framer role by the component. This event is only possible on bus boot (when default active framer) and incoming framer handover (when inactive framer).

##### **23.9.4.12.4.4.2 Interrupt Service Routine**

Assert software implemented ACTIVE\_FRAMER information element.

Field [SLIMBUS\\_FR\\_INFO](#)[4] FRAMER\_UNACTIVATED must be software cleared (by writing 1 to it).

Note that the ACTIVE\_FRAMER information element's assertion does not trigger the transmission by the framer device of a REPORT\_INFORMATION message, since the information is already "publicized" by the framer handover process.

#### **23.9.4.12.4.5 Framer device un-activated (FRAMER\_UNACTIVATED)**

##### **23.9.4.12.4.5.1 Root Event**

Loss of active framer role by the component. This event is only possible on bus shutdown and outgoing framer handover (when active framer).

##### **23.9.4.12.4.5.2 Interrupt Service Routine**

Deassert software-implemented ACTIVE\_FRAMER information element.

Field [SLIMBUS\\_FR\\_INFO](#)[3] FRAMER\_ACTIVATED must be software cleared (by writing 1 to it).

Note that the ACTIVE\_FRAMER information element's deassertion does not trigger the transmission by the framer device of a REPORT\_INFORMATION message, since the information is already "publicized" by the framer handover process.

#### **23.9.4.12.4.6 Restart after clock pause (CLOCK\_RESTART)**

##### **23.9.4.12.4.6.1 Root Event**

Transition detected on the DATA line during a clock pause, driven by any of the connected components and seen by the clock source (active framer) as a restart request. Note that this field is set for all clock restarts, even if the local framer is inactive.

##### **23.9.4.12.4.6.2 Interrupt Service Routine**

Field [SLIMBUS\\_FR\\_INFO](#)[5] CLOCK\_RESTART must be software cleared (by writing 1 to it).

---

**NOTE:** Restart event is a source of asynchronous wakeup.

---

#### **23.9.4.12.5 Shared Message Channel Transmit ISRs**

These ISRs are applied when a bit of status register SMT\_INFO is set, which also triggers the assertion of bit field [SLIMBUS\\_CMP\\_IRQSTATUS](#)[2] SMT\_INFO and of the IRQ line, when enabled in bit field [SLIMBUS\\_CMP\\_IRQENABLE\\_SET](#)[2] SMT\_INFO\_EN. Service routines must be applied, and the fr\_info bit field cleared (by writing 1 to it)

### **23.9.4.12.5.1 Transmit collision in message body (MC\_TX\_COL)**

#### **23.9.4.12.5.1.1 Root Event**

Transmit collision detected while transmitting a message, that is, writing any subfield except message response (arbitration, header, payload, or message integrity). The device immediately (before next cell) stop transmission and the component automatically lose message synchronization. The message has to be sent again, once message synchronization has been regained.

#### **23.9.4.12.5.1.2 Interrupt Service Routine**

This field, [SLIMBUS\\_SMT\\_INFO\[0\]](#) MC\_TX\_COL, is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST\_CLEAR\_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

### **23.9.4.12.5.2 TX message FIFO overflow (OVERFLOW)**

#### **23.9.4.12.5.2.1 Root Event**

Overflow occurs when too many bytes are written into the TX message FIFO by the software, either because the entered message is too long or because the FIFO still contains bytes from previous messages. The state of the FIFO after an overflow event is undetermined, but the other FIFOs are unaffected.

#### **23.9.4.12.5.2.2 Interrupt Service Routine**

TX message FIFO must be cleared as explained in [Section 23.9.4.11.1.2](#).

Field [SLIMBUS\\_SMT\\_INFO\[1\]](#) OVERFLOW must be software cleared (by writing 1 to it).

Message transmission must resume normally.

### **23.9.4.12.5.3 Received positive acknowledge message response (PACK)**

#### **23.9.4.12.5.3.1 Root Event**

Message written in the TX message FIFO was transmitted after unlimited, automatic arbitration retries, and removed from the FIFO. Received message response (MR) is PACK.

#### **23.9.4.12.5.3.2 Interrupt Service Routine**

No action required for this field: [SLIMBUS\\_SMT\\_INFO\[2\]](#) PACK. FIFO is now available for another message.

### **23.9.4.12.5.4 Received negative acknowledge message response (NACK)**

#### **23.9.4.12.5.4.1 Root Event**

Message written in the TX message FIFO was transmitted after unlimited, automatic arbitration retries, and removed from the FIFO. Received message response (MR) is NACK.

#### **23.9.4.12.5.4.2 Interrupt Service Routine**

Current message must be eventually retransmitted until it succeeds or until the retransmit maximum (fully managed by software) is reached.

Field [SLIMBUS\\_SMT\\_INFO\[3\]](#) NACK must be software cleared (by writing 1 to it).

FIFO is available for another message, which can be the same or another one.

### **23.9.4.12.5.5 Received no message response (NORE)**

#### **23.9.4.12.5.5.1 Root Event**

Message written in the TX message FIFO was transmitted after unlimited, automatic arbitration retries, and removed from the FIFO. Received message response (MR) is NORE.

#### **23.9.4.12.5.5.2 Interrupt Service Routine**

Current message must be eventually retransmitted until it succeeds or until the retransmit maximum (fully managed by software) is reached.

Field [SLIMBUS\\_SMT\\_INFO](#)[4] NORE must be software cleared (by writing 1 to it).

FIFO is available for another message, which can be the same or another one.

### **23.9.4.12.5.6 Received undefined message response (UDEF)**

#### **23.9.4.12.5.6.1 Root Event**

Message written in the TX message FIFO was transmitted after unlimited, automatic arbitration retries, and removed from the FIFO. Received message response (MR) is UDEF, that is, one of several undefined MR codes that are not combinations of legal responses, implying that an error has taken place. Component loses message synchronization, and reacquires it automatically.

#### **23.9.4.12.5.6.2 Interrupt Service Routine**

Field [SLIMBUS\\_SMT\\_INFO](#)[5] UDEF must be software cleared (by writing 1 to it).

FIFO is available for another message, which can be the same or another one.

### **23.9.4.12.5.7 TX message FIFO underflow (UNDERFLOW)**

#### **23.9.4.12.5.7.1 Root Event**

Underflow takes place when the message transmission logic attempts to read more bytes than the FIFO contains. The state of the FIFO after an underflow event is undetermined, but the other FIFOs are unaffected.

#### **23.9.4.12.5.7.2 Interrupt Service Routine**

TX message FIFO must be cleared as explained in [Section 23.9.4.11.1.2](#).

Field must be software-cleared (by writing 1 to it).

Message transmission must resume normally, making sure the error is not repeated.

### **23.9.4.12.6 Shared Message Channel Receive ISRs**

These ISRs are applied when a bit of status register [SMR\\_INFO](#) is set, which also triggers the assertion of bit field [SLIMBUS\\_CMP\\_IRQSTATUS](#)[3] [SMR\\_INFO](#) and of the IRQ line, when enabled in bit field [SLIMBUS\\_CMP\\_IRQENABLE\\_SET](#)[3] [SMR\\_INFO\\_EN](#). Service routines must be applied, and the [FR\\_INFO](#) bit field cleared (by writing 1 to it)

### **23.9.4.12.6.1 Transmit collision in message response (MC\_TX\_COL)**

#### **23.9.4.12.6.1.1 Root Event**

Transmit collision detected while receiving a message, that is, writing the message response subfield. The component automatically loses message synchronization, and eventually reacquires it.

### **23.9.4.12.6.1.2 Interrupt Service Routine**

The field [SLIMBUS\\_SMR\\_INFO\[0\] MC\\_TX\\_COL](#) must not be unconditionally software cleared, as it implements a Boolean IE that can only be cleared under specific conditions (and together with the [SLIMBUS\\_SMT\\_INFO\[0\] MC\\_TX\\_COL](#)).

### **23.9.4.12.6.2 RX message FIFO underflow (UNDERFLOW)**

#### **23.9.4.12.6.2.1 Root Event**

Underflow takes place when too many bytes are read out of the RX message FIFO by the software, because of an error when estimating the message length, as defined in [Section 23.9.4.11.2.2](#). The state of the FIFO after an underflow event is undetermined, but the other FIFOs are unaffected.

#### **23.9.4.12.6.2.2 Interrupt Service Routine**

RX message FIFO must be cleared as explained in [Section 23.9.4.11.2.3](#).

Field [SLIMBUS\\_SMR\\_INFO\[1\] UNDERFLOW](#) must be software-cleared (by writing 1 to it).

---

**NOTE:** This software error is not supposed to take place, since the message itself is assumed to be correct and could affect the correct running of the SLIMbus protocol, if the received message cannot be recovered.

---

### **23.9.4.12.6.3 RX message FIFO overflow (OVERFLOW)**

#### **23.9.4.12.6.3.1 Root Event**

Overflow occurs when too many bytes are received into the RX message FIFO because the entered message is too long. The state of the FIFO after an overflow event is undetermined, but the other FIFOs are unaffected.

#### **23.9.4.12.6.3.2 Interrupt Service Routine**

RX message FIFO must be cleared as explained in [Section 23.9.4.11.2.3](#).

Field must be software cleared (by writing 1 to it).

Message transmission must resume normally.

### **23.9.4.12.6.4 Message received (RECEIVED\_MESSAGE)**

#### **23.9.4.12.6.4.1 Root Event**

A message has been received and checked by the hardware: target address matches a local device (LA or EA), message length is coherent with AT/RL fields, integrity is correct for both PI and MI, all target devices acknowledged the message (PACK MR transmitted and received).

#### **23.9.4.12.6.4.2 Interrupt Service Routine**

Received message must be unloaded from RX message FIFO, parsed, and the appropriate action taken, as explained in [Section 23.9.4.11.2.2](#).

Field [SLIMBUS\\_SMR\\_INFO\[2\] RECEIVED\\_MESSAGE](#) must be software cleared (by writing 1 to it). This will also clear the message FIFO and allow the local component to respond PACK to new incoming messages.

### 23.9.4.12.6.5 Reconfigure\_now message received (RECEIVED\_RECONFIGURE)

#### 23.9.4.12.6.5.1 Root Event

A message has been received as in RECEIVED\_MESSAGE event above, with the additional condition that it has been recognized by hardware as a RECONFIGURE\_NOW() message. Note that by the time the ISR is executed, the reconfiguration may have already taken place.

#### 23.9.4.12.6.5.2 Interrupt Service Routine

Field [SLIMBUS\\_SMR\\_INFO\[3\]](#) RECEIVED\_CONFIGURE must be software cleared (by writing 1 to it).

### 23.9.4.12.7 Data Channel Port ISRs

These ISRs are applied when a bit of a status register [SLIMBUS\\_DCT\\_INFO\\_j](#) and/or [SLIMBUS\\_DCR\\_INFO\\_j](#) is set, which also triggers the assertion of bit field [SLIMBUS\\_CMP\\_IRQSTATUS\[11:4\]](#) DCT\_INFO\_j/DCR\_INFO\_j and of the IRQ line, when enabled in bit field [SLIMBUS\\_CMP\\_IRQENABLE\\_SET\[11:4\]](#) DCT/DCR\_INFO\_j. Service routines must be applied, and the [SLIMBUS\\_DCT\\_INFO\\_j](#) and/or [SLIMBUS\\_DCR\\_INFO\\_j](#) bit fields cleared (by writing 1 to it).

#### 23.9.4.12.7.1 Transmit collision in data channel port (DATA\_TX\_COL)

##### 23.9.4.12.7.1.1 Root Event

Transmit collision detected while writing to the considered data channel, in any of the TAG, AUX, or DATA fields. Note that transmit collisions are possible even for receive ports, as those port may also write some TAG cells (e.g. for pulled TP), where transmit collisions are possible. The device must immediately (before next cell) stop writing to the bus, only resuming on next segment.

##### 23.9.4.12.7.1.2 Interrupt Service Routine

The REPORT\_INFORMATION message must be transmitted, from the port's stereo or voice device (that is, with that device's LA in source address of arbitration field), to the active manager (that is, with manager's target [SLIMBUS\\_DEV\\_LA\\_j\[7:0\]](#) LA in header = 0xFF), and containing the information element (IE) of the same name (DATA\_TX\_COL).

The field [SLIMBUS\\_DCT\\_INFO\\_j\[0\]](#) DATA\_TX\_COL and/or [SLIMBUS\\_DCR\\_INFO\\_j\[0\]](#) DATA\_TX\_COL must not be unconditionally software cleared, as it implements a boolean IE that can only be cleared under specific conditions.

#### 23.9.4.12.7.2 Data channel FIFO overflow (OVERFLOW)

##### 23.9.4.12.7.2.1 Root Event

Overflow takes place when the data rate into the FIFO exceeds the data rate out of the FIFO for a sufficient amount of time, which can happen in both TX and RX ports. The state of the FIFO after an overflow event is undetermined, but the other FIFOs are unaffected.

##### 23.9.4.12.7.2.2 Interrupt Service Routine

The SLIMbus protocol does not specify the handling of such an event. However, since data integrity cannot be guaranteed following an that event, stopping the channel is an option.

Field [SLIMBUS\\_DCT\\_INFO\\_j\[1\]](#) / [SLIMBUS\\_DCR\\_INFO\\_j\[1\]](#) OVERFLOW must be software cleared (by writing 1 to it).

### **23.9.4.12.7.3 5.5.2 Data channel FIFO underflow (UNDERFLOW)**

#### **23.9.4.12.7.3.1 Root Event**

Overflow takes place when the data rate out of the FIFO exceeds the data rate into the FIFO for a sufficient amount of time, which can happen in both TX and RX ports. The state of the FIFO after an underflow event is undetermined, but the other FIFOs are unaffected.

#### **23.9.4.12.7.3.2 Interrupt Service Routine**

The SLIMbus protocol does not specify the handling of such an event. However, since data integrity cannot be guaranteed following an that event, stopping the channel is an option.

Field `SLIMBUS_DCT_INFO_j[2]` / `SLIMBUS_DCR_INFO_j[2]` UNDERFLOW must be software cleared (by writing 1 to it).

## 23.9.5 SLIMbus Programming Guide

### 23.9.5.1 SLIMbus Low-level Programming Models

This section covers the low-level programming sequences for configuration and usage of the SLIMbus module.

#### 23.9.5.1.1 Global Initialization

##### 23.9.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the SLIMbus module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the SLIMbus. See [Section 23.9.3](#) and [Section 23.9.2](#) for further information.

**Table 23-670. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	All SLIMbus clocks must be enabled. For SLIMbus clocks summary see <a href="#">Table 23-651</a> . See <a href="#">Chapter 3, Power, Reset, and Clock Management</a>
L4 Interconnect	For information about L4-PER interconnect configuration, see <a href="#">Chapter 13, Interconnect</a> .
sDMA	sDMA configuration must be done to enable the module DMA channel requests. See <a href="#">Chapter 16 SDMA</a> .
INTC	Cortex-A9 MPU and DSP subsystems interrupt controller must be configured to enable the interrupt request generation to the Cortex-A9 MPU, <a href="#">Chapter 4</a> or to the DSP subsystem, <a href="#">Chapter 5</a> .

#### 23.9.5.1.1.2 SLIMbus Global Initialization

##### 23.9.5.1.1.2.1 SLIMbus module software reset

This procedure performs software reset to the SLIMbus module.

**Table 23-671. SLIMbus component reset**

Step	Register / Bit Field / Programming Model	Value
Perform a software Reset	SLIMBUS_CMP_SYSCONFIG[0] SOFTRESET	0x1
Wait until Reset is finished?	SLIMBUS_CMP_SYSCONFIG[0] SOFTRESET	=0x0

##### 23.9.5.1.1.2.2 Power Management and Wakeup Configuration

This procedure configures the idle mode for SLIMbus component. By definition, target can handle read/write transaction as long as it is out of IDLE state.

**Table 23-672. SLIMbus idle mode configuration**

Step	Register / Bit Field / Programming Model	Value
Set slave idle mode	SLIMBUS_CMP_SYSCONFIG[3:2] IDLEMODE	0x-
Turn on/off internal clock autogating	SLIMBUS_CMP_SYSCONFIG[8] AUTOGATINGDISABLE	0x-

##### 23.9.5.1.1.2.3 SLIMbus FIFOs mapping and setup

This procedure maps each used FIFO to a free zone of the shared buffer prior to enabling. Also sets the FIFO thresholds used to trigger loading/unloading the FIFOs.

**Table 23-673. SLIMbus FIFOs mapping and setup**

Step	Register / Bit Field / Programming Model	Value
Set the capacity of data FIFO for RX channel j	SLIMBUS_DCR_FIFO_SETUP2_j[7:0] SIZE	0x--
Set the capacity of data FIFO for TX channel j	SLIMBUS_DCT_FIFO_SETUP2_j[7:0] SIZE	0x--
Select shared message channel RX FIFO size	SLIMBUS_SMR_FIFO_SETUP[6:5] SIZE_HI	0x-
Select shared message channel TX FIFO size	SLIMBUS_SMT_FIFO_SETUP[6:5] SIZE_HI	0x-
Set RX data channel agent j FIFO base address within shared RAM	SLIMBUS_DCR_FIFO_SETUP1_j[11:5] BASE_ADDR	0x--
Set TX data channel agent j FIFO base address within shared RAM	SLIMBUS_DCT_FIFO_SETUP1_j[11:5] BASE_ADDR	0x--
Set SLIMbus-side RX data channel agent j FIFO threshold, used for SLIMbus reception	SLIMBUS_DCR_FIFO_SETUP2_j[15:8] SB_THRESHOLD	0x--
Set SLIMbus-side TX data channel agent j FIFO threshold, used for SLIMbus transmission	SLIMBUS_DCT_FIFO_SETUP2_j[15:8] SB_THRESHOLD	0x--
Set software-side RX data channel agent's j FIFO threshold.	SLIMBUS_DCR_FIFO_SETUP2_j[23:16] DMA_THRESHOLD	0x--
Set software-side TX data channel agent's j FIFO threshold.	SLIMBUS_DCT_FIFO_SETUP2_j[23:16] DMA_THRESHOLD	0x--

### 23.9.5.1.2 Operational Modes Configuration

#### 23.9.5.1.2.1 SLIMbus transfer protocol configuration

This procedure configures the data channel(s) for a specific transfer protocol use. Values for each bit field vary depending on transfer protocol as shown in table [Table 23-675](#).

**Table 23-674. SLIMbus transfer protocol configuration sequence**

Step	Register / Bit Field / Programming Model	Value
Select asynchronous mode for RX data channel j	SLIMBUS_DCR_CONFIG1_j[3:0] TP	0x-
Select asynchronous mode for TX data channel j	SLIMBUS_DCT_CONFIG1_j[3:0] TP	0x-
Select ownership for RX data channel j	SLIMBUS_DCR_CONFIG1_j[4] TP_QUALIFIER	0x-
Select ownership for TX data channel j	SLIMBUS_DCT_CONFIG1_j[4] TP_QUALIFIER	0x-
Set segment length RX for data channel j	SLIMBUS_DCR_CONFIG1_j[9:5] SL	0x--
Set segment length TX for data channel j	SLIMBUS_DCT_CONFIG1_j[9:5] SL	0x--
Select number of AUX slots in segment for RX data channel j	SLIMBUS_DCR_CONFIG1_j[19:16] AF	0x--
Select number of AUX slots in segment for TX data channel j	SLIMBUS_DCT_CONFIG1_j[19:16] AF	0x--
Set data length (data slots in segment) for RX data channel j	SLIMBUS_DCR_CONFIG1_j[14:10] DL	0x--
Set data length (data slots in segment) for TX data channel j	SLIMBUS_DCT_CONFIG1_j[14:10] DL	0x--
Enable/Disable RX data channel n pairing with RX channel j-1	SLIMBUS_DCR_CONFIG1_j[15] CL	0x-
Enable/Disable TX data channel n pairing with TX channel j-1	SLIMBUS_DCT_CONFIG1_j[15] CL	0x-
Enable RX data channel j	SLIMBUS_DCR_CONFIG1_j[31] ENABLE	0x1
Enable TX data channel j	SLIMBUS_DCT_CONFIG1_j[31] ENABLE	0x1
Set segment periodicity and offset for RX data channel j	SLIMBUS_DCR_CONFIG2_j[11:0] SD	0x---
Set segment periodicity and offset for TX data channel j	SLIMBUS_DCT_CONFIG2_j[11:0] SD	0x---

**Table 23-675. SLIMbus transfer protocol configuration**

Register / Bit Field	Isochronous TP	Pushed TP	Pulled TP	"Plain" Asynchronous simplex TP	"Plain" Asynchronous 1/2 duplex TP	Extended Asynchronous simplex TP	Extended Asynchronous 1/2 duplex TP
SLIMBUS_DCR_CONFIG1_j[3:0] TP SLIMBUS_DCT_CONFIG1_j[3:0] TP	0x0	0x1	0x2	0x4	0x5	0x6	0x7
SLIMBUS_DCR_CONFIG1_j[4] TP_QUALIFIER SLIMBUS_DCT_CONFIG1_j[4] TP_QUALIFIER	unused	unused	unused	0x0, 0x1	0x0, 0x1	0x0, 0x1	0x0, 0x1
SLIMBUS_DCR_CONFIG1_j[9:5] SL SLIMBUS_DCT_CONFIG1_j[9:5] SL	0x2...0x8	0x3...0x9	0x3...0x9	0x3...0x9	0x3...0x9	0x4...0x1F	0x4...0x1F
SLIMBUS_DCR_CONFIG1_j[19:16] AF SLIMBUS_DCT_CONFIG1_j[19:16] AF	0x0...0x2	0x0...0x2	0x0...0x2	0x0...0x2	0x0...0x2	0x0	0x0
SLIMBUS_DCR_CONFIG1_j[14:10] DL SLIMBUS_DCT_CONFIG1_j[14:10] DL	0x2...0x8	0x2...0x8	0x2...0x8	0x2...0x8	0x2...0x8	0x2	0x2
SLIMBUS_DCR_CONFIG1_j[15] CL SLIMBUS_DCT_CONFIG1_j[15] CL	0x0, 0x1	0x0, 0x1	0x0, 0x1	0x0	0x0	0x0	0x0
SLIMBUS_DCR_CONFIG2_j[11:0] SD SLIMBUS_DCT_CONFIG2_j[11:0] SD	0x---	0x---	0x---	0x---	0x---	0x---	0x---

More about SLIMbus protocol configuration see in [Section 23.9.4.8 SLIMbus Transfer Protocols](#).

### 23.9.5.1.2.2 SLIMbus interrupts configuration

This procedure selects the required interrupt sources for generating interrupts.

**Table 23-676. SLIMbus interrupts enabling**

Step	Register / Bit Field / Programming Model	Value
Enable required interrupt sources (for SLIMbus1)	SLIMBUS_CMP_IRQENABLE_SET[19:0]	0x----
Enable required interrupt sources (for SLIMbus2)	SLIMBUS_CMP_IRQENABLE_SET[11:0]	0x---
Disable the rest of interrupt sources (for SLIMbus1)	SLIMBUS_CMP_IRQENABLE_CLR[19:0]	0x----
Disable the rest of interrupt sources (for SLIMbus2)	SLIMBUS_CMP_IRQENABLE_CLR[11:0]	0x---
Clear the interrupt status register (for SLIMbus1)	SLIMBUS_CMP_IRQSTATUS[19:0]	0xFFFFF
Clear the interrupt status register (for SLIMbus2)	SLIMBUS_CMP_IRQSTATUS[11:0]	0xFFF

### 23.9.5.1.2.3 SLIMbus DMA configuration

This procedure selects and configures the channels for DMA mode use.

**Table 23-677. SLIMbus DMA configuration**

Step	Register / Bit Field / Programming Model	Value
Select DMA request size minus 1, in FIFO words for RX data channel j	SLIMBUS_DCR_FIFO_SETUP1_j[4:1] DMA_REQ_SIZE	0x-
Select DMA request size minus 1, in FIFO words for TX data channel j	SLIMBUS_DCT_FIFO_SETUP1_j[4:1] DMA_REQ_SIZE	0x-
Enable DMA mode for required data channels (for SLIMbus1) <sup>(1)</sup>	SLIMBUS_CMP_DMAENABLE_SET [19:4]	0x----
Enable DMA mode for required data channels (for SLIMbus2)	SLIMBUS_CMP_DMAENABLE_SET [11:4]	0x--
Disable DMA mode for the rest of channels (for SLIMbus1) <sup>(1)</sup>	SLIMBUS_CMP_DMAENABLE_CLR [19:4]	0x----
Disable DMA mode for the rest of channels (for SLIMbus2)	SLIMBUS_CMP_DMAENABLE_CLR [11:4]	0x--

<sup>(1)</sup> Component level registers (e.g. with CMP in name) composition (bit fields used) depends on the SLIMbus component instantiation - SLIMbus1 or SLIMbus2.

### 23.9.5.1.2.4 SLIMbus Component Boot

Component boot sequence is initiated when the component decides to join the bus. More about SLIMbus boot and reset procedures see in [Section 23.9.4.4.3](#)

#### 23.9.5.1.2.4.1 Clock Receiver Component Boot

This procedure boots the SLIMbus configuration when the component is in clock receiver mode.

**Table 23-678. Clock Receiver Component Boot**

Step	Register / Bit Field / Programming Model	Value
Set clock receiver component boot flag	SLIMBUS_FL_CONTROL[0] BOOT	0x1
Initiate the sequence	SLIMBUS_FL_CONTROL[2] FORCE_RECONFIGURE	0x1

#### 23.9.5.1.2.4.2 Clock Source Component Boot

This procedure boots the SLIMbus when the component is in clock source mode (includes the active framer).

**Table 23-679. Clock Source Component Boot**

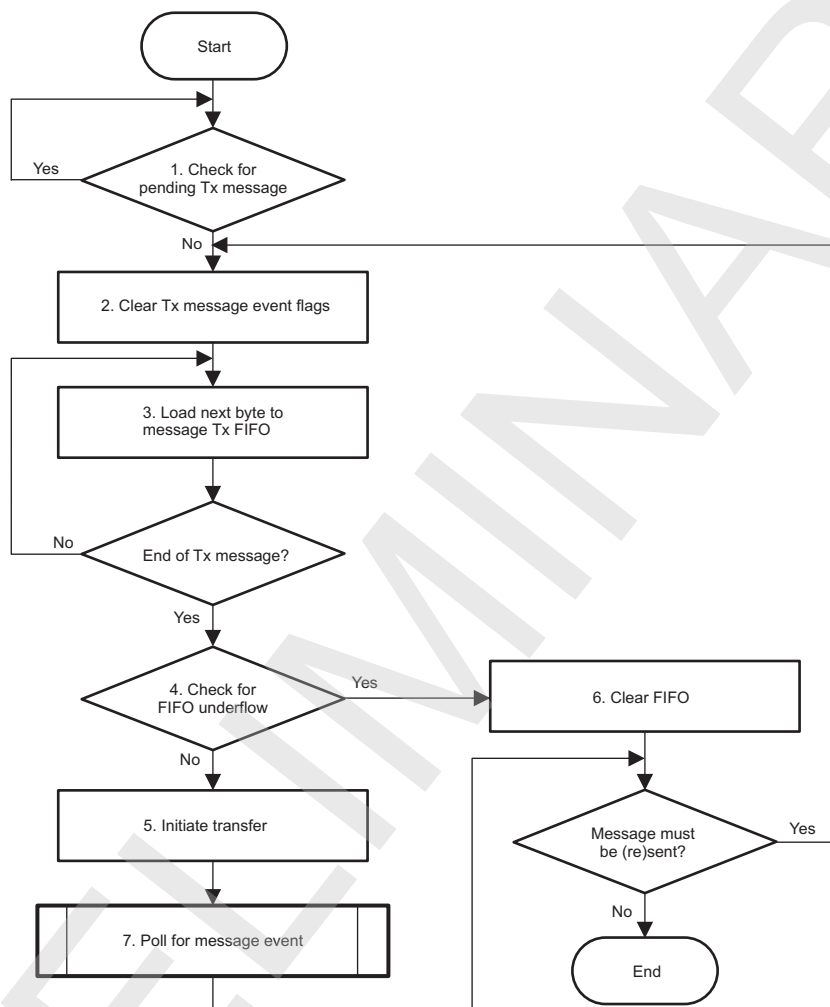

Step	Register / Bit Field / Programming Model	Value
Set clock source component boot flag	SLIMBUS_FR_CONTROL[0] BOOT	0x1
Select control space width and subframe length	SLIMBUS_FL_SM[4:0] SM	0x--
Select Root / SLIMbus frequency ratio (Clock Gear)	SLIMBUS_FL_CG[3:0] CG	0x-
Set the Root frequency	SLIMBUS_FL_RF[3:0] RF	0x-
Select input clock source	SLIMBUS_FR_CLOCK_SOURCE[5:3] CLKSEL	0x-
Select Root divider ratio to obtain the Root frequency	SLIMBUS_FR_CLOCK_SOURCE[2:0] CLKDIV	0x-
Initiate the sequence	SLIMBUS_FL_CONTROL[2] FORCE_RECONFIGURE	0x1

### 23.9.5.1.3 SLIMbus Transfer Procedures

#### 23.9.5.1.3.1 Transmitting Message, Polling Mode

This procedure transmits a message over the SLIMbus without using interrupts.

**Figure 23-216. Transmitting Message, Polling Mode Procedure**

slimbus-012

**Table 23-680. Register Settings for the SLIMbus Message Transmit Procedure, Polling Method**

Procedure Name	Description	Register settings
1. Check for pending TX message	This procedure checks whether ongoing TX message is in progress. This also implies that TX message FIFO can receive another message. <code>SLIMBUS_SMT_CONTROL[0] MESSAGE_ENABLE = 0</code> means there is no ongoing TX message in FIFO.	Check <code>SLIMBUS_SMT_CONTROL[0] MESSAGE_ENABLE = 0</code> ?
2. Clear TX message event flags	This procedure clears TX message event flags by writing 1 to the corresponding bit(s). Failing to meet this condition will not prevent the message transmission, but will prevent a proper readout of the message transmission's outcome.	Write <code>SLIMBUS_SMT_INFO[5:0] = 0x3F</code>

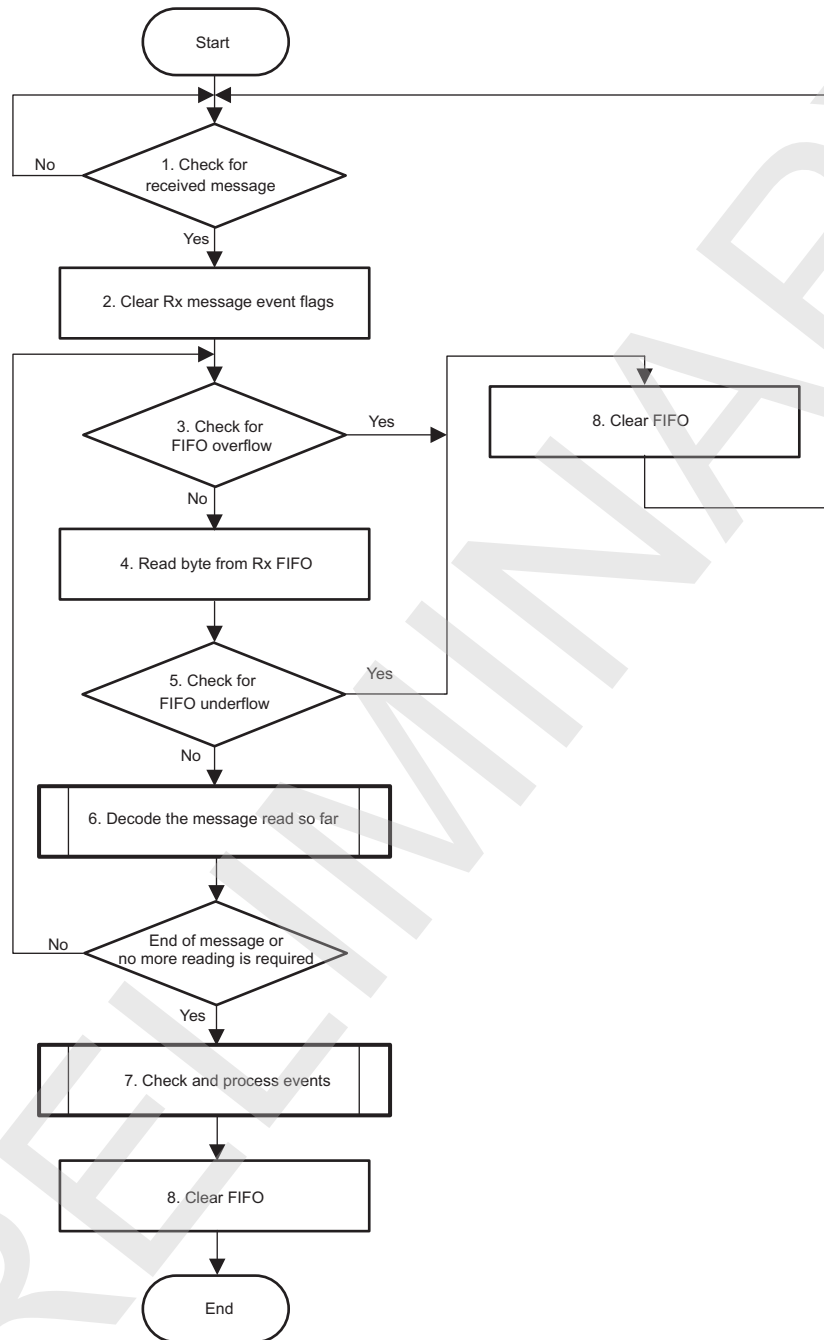

**Table 23-680. Register Settings for the SLIMbus Message Transmit Procedure, Polling Method  
(continued)**

Procedure Name	Description	Register settings
3. Load byte to TX FIFO	The message is written byte by byte to register <a href="#">SLIMBUS_SMT_MESSAGE</a> [7:0]. Serial message starts with the MSB (bit 7) of the first byte written into the FIFO and ends with the LSB (bit 0) of the last written byte.	Write <a href="#">SLIMBUS_SMT_MESSAGE</a> [7:0] = 0x--
4. Check for FIFO underflow	This procedure checks if an underflow event is flagged (stored message is shorter than encoded in its own AT, RL fields).	Check <a href="#">SLIMBUS_SMT_INFO</a> [6] UNDERFLOW = 1?
5. Initiate transfer	This procedure initiates the transmit sequence. From that point on, the device will attempt to transmit the message stored in the FIFO.	Write <a href="#">SLIMBUS_SMT_CONTROL</a> [0] MESSAGE_ENABLE = 1
6. Clear FIFO	This procedure clears the FIFO in case of error.	Write <a href="#">SLIMBUS_SMT_CONTROL</a> [0] MESSAGE_ENABLE = 0
7. Poll message events	Transmission is considered complete if one of the following -mutually exclusive- conditions is met, and the corresponding bit of <a href="#">SLIMBUS_SMT_INFO</a> is set: Negative response: <a href="#">SLIMBUS_SMT_INFO</a> [3] NACK = 1, or Positive response: <a href="#">SLIMBUS_SMT_INFO</a> [2] PACK = 1, or No response: <a href="#">SLIMBUS_SMT_INFO</a> [4] NORE = 1, or Illegal response: <a href="#">SLIMBUS_SMT_INFO</a> [5] UDEF = 1, or Transmit collision: <a href="#">SLIMBUS_SMT_INFO</a> [0] MC_TX_COL = 1	<ol style="list-style-type: none"> <li>1. Poll <a href="#">SLIMBUS_SMT_INFO</a>[7:0]</li> <li>2. Process the event as required</li> <li>3. Clear the corresponding info bit</li> </ol>

**NOTE:** For more information about SMT events see [Section 23.9.4.12.5 Shared Message Channel Transmit ISRs](#).  
For information about all SLIMbus events see [Section 23.9.4.12.2 Possible Interrupts](#).

### 23.9.5.1.3.2 Receiving Message, Polling Mode

This procedure reads any received in FIFO message without using interrupts.

**Figure 23-217. Receiving Message, Polling Mode Procedure**

slimbus-013

**Table 23-681. Register Settings for the SLIMbus message receive procedure, Polling Method**

Procedure Name	Description	Register settings
1. Check for received message	This procedure checks whether a message is received in FIFO.	Check <code>SLIMBUS_SMR_INFO[2] RECEIVED_MESSAGE = 1?</code>
2. Clear RX message event flags	This procedure clears pending (at 1) RX message event flags by writing 1 to the corresponding bit(s).	Write <code>SLIMBUS_SMR_INFO[4:0] = 0x1F</code>

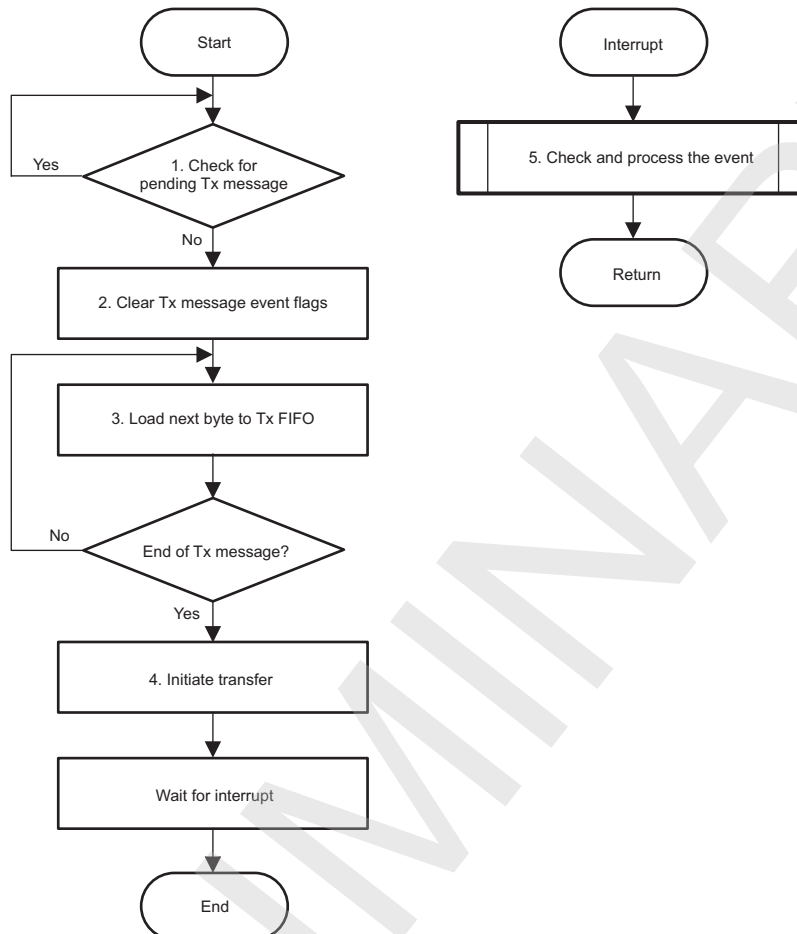

**Table 23-681. Register Settings for the SLIMbus message receive procedure, Polling Method (continued)**

Procedure Name	Description	Register settings
3. Check for FIFO overflow	This procedure checks whether overflow event is flagged ( too many bytes are received, which will overwrite previous bytes.)	Check <code>SLIMBUS_SMR_INFO[1] OVERFLOW = 1?</code>
4. Read byte from RX FIFO	The message is read byte by byte off the FIFO and put into register <code>SLIMBUS_SMR_MESSAGE[7:0]</code> .	Read <code>SLIMBUS_SMR_MESSAGE[7:0]</code>
5. Check for FIFO underflow	This procedure checks if an underflow event is flagged (too many bytes are read out ).	Check <code>SLIMBUS_SMR_INFO[1] UNDERFLOW = 1?</code>
6. Decode the read so far message	This procedure takes place in parallel with the unloading phase. In some cases, a partial decoding can lead the software to skip the end of the unloading and flush the FIFO.	Decoding the message is entirely done by software
7. Check and process events	This procedure checks and processes any pending events.	<ol style="list-style-type: none"> <li>1. Poll <code>SLIMBUS_SMR_INFO[4:0]</code></li> <li>2. Process events as required</li> <li>3. Clear the corresponding info bit</li> </ol>
8. Clear FIFO	This procedure clears the FIFO in order to be ready to receive a new message, or in case of error	Write <code>SLIMBUS_SMR_INFO[2] RECEIVED_MESSAGE = 1</code>

**NOTE:** For more information about SMR events see [Section 23.9.4.12.6 Shared Message Channel Receive ISRs](#).  
For information about all SLIMbus events see [Section 23.9.4.12.2 Possible Interrupts](#).

### 23.9.5.1.3.3 Transmitting message, interrupt mode

This procedure transmits a message over the SLIMbus using interrupts for event handling. Interrupts must be enabled as shown in [Section 23.9.5.1.2.2 SLIMbus interrupts configuration](#).

**Figure 23-218. Transmitting message, interrupt mode procedure**

slimbus-014

**Table 23-682. Register Settings for the SLIMbus message transmit procedure, Interrupt Method**

Procedure Name	Description	Register settings
<b>Main routine</b>		
1. Check for pending TX message	This procedure checks whether ongoing TX message is in progress. This also implies that TX message FIFO can receive another message. <b>SLIMBUS_SMT_CONTROL[0] MESSAGE_ENABLE = 0</b> means there is no ongoing TX message in FIFO.	Check <b>SLIMBUS_SMT_CONTROL[0] MESSAGE_ENABLE = 0?</b>
2. Clear TX message event flags	This procedure clears TX message event flags by writing 1 to the corresponding bit(s). Failing to meet this condition will not prevent the message transmission, but will prevent a proper readout of the message transmission's outcome	Write <b>SLIMBUS_SMT_INFO[5:0] = 0x3F</b>
3. Load byte to TX FIFO	The message is written byte by byte to register <b>SLIMBUS_SMT_MESSAGE[7:0]</b> . Serial message starts with the MSB (bit 7) of the first byte written into the FIFO and ends with the LSB (bit 0) of the last written byte.	Write <b>SLIMBUS_SMT_MESSAGE[7:0] = 0x--</b>
4. Initiate transfer	This procedure initiates the transmit sequence. From that point on, the device will attempt to transmit the message stored in the FIFO.	Write <b>SLIMBUS_SMT_CONTROL[0] MESSAGE_ENABLE = 1</b>
<b>Interrupt subroutine</b>		

**Table 23-682. Register Settings for the SLIMbus message transmit procedure, Interrupt Method (continued)**

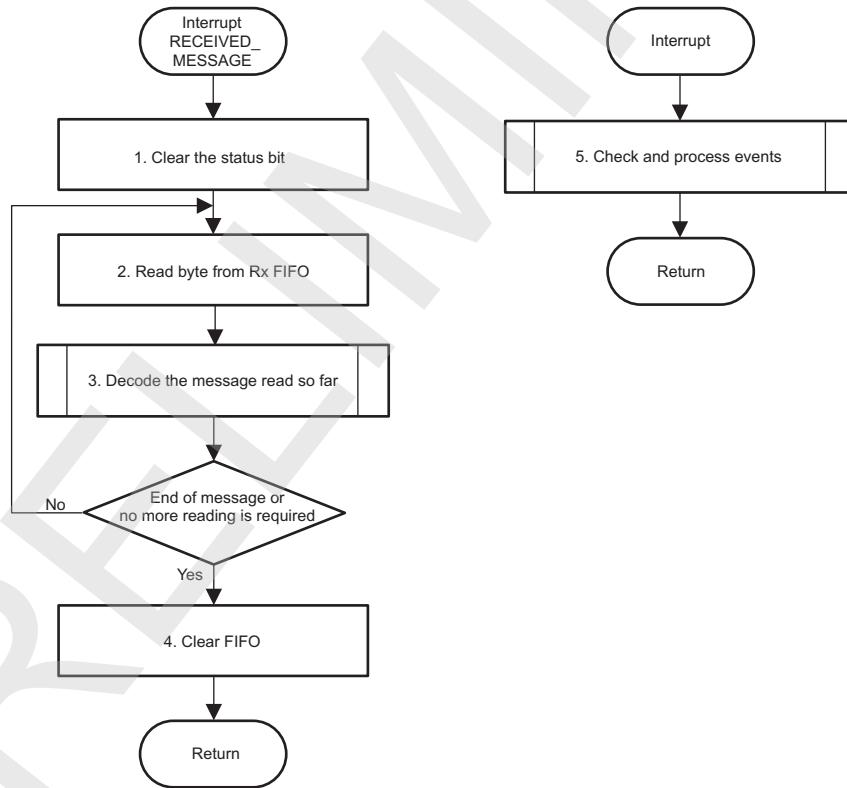

Procedure Name	Description	Register settings
5. Check and process events	<ol style="list-style-type: none"> <li>1. Clear the corresponding status bit</li> <li>2. Check the pending event by polling the related information register's flags.</li> <li>3. Process the event as required. For more information see <a href="#">Section 23.9.4.12.5</a> SLIMbus Shared Message Channel Transmit ISRs</li> <li>4. When needed and allowed, clear the information register</li> </ol>	<ol style="list-style-type: none"> <li>1. Write <code>SLIMBUS_CMP_IRQSTATUS[2]</code> <code>SMT_INFO = 1</code></li> <li>2. Poll <code>SLIMBUS_SMT_INFO[7:0]</code></li> <li>3. Process the event as required</li> <li>4. Write <code>SLIMBUS_SMT_INFO[7:0] = 0xFF</code></li> </ol>

**NOTE:** For information about all SLIMbus events see [Section 23.9.4.12.2](#) Possible interrupts.

**23.9.5.1.3.4 Receiving message, interrupt mode**

This procedure reads the received in FIFO message and processes any pending events using interrupts. Interrupts must be enabled as shown in [Section 23.9.5.1.2.2](#) SLIMbus interrupts configuration.

**Figure 23-219. Receiving message, interrupt mode procedure**

slimbus-015

**Table 23-683. Register Settings for the SLIMbus message receive procedure, Transmit Method**

Procedure Name	Description	Register settings
Main interrupt routine		
1. Clear the status bit	This procedure clears the interrupt status bit, if it is not already cleared.	Write <code>SLIMBUS_CMP_IRQSTATUS[3]</code> <code>SMR_INFO = 1</code>

**Table 23-683. Register Settings for the SLIMbus message receive procedure, Transmit Method (continued)**

Procedure Name	Description	Register settings
2. Read byte from RX FIFO	The message is read byte by byte off the FIFO and put into register <code>SLIMBUS_SMR_MESSAGE[7:0]</code> .	Read <code>SLIMBUS_SMR_MESSAGE[7:0]</code>
3. Decode the read so far message	This procedure takes place in parallel with the unloading phase. In some cases, a partial decoding can lead the software to skip the end of the unloading and flush the FIFO.	Decoding of the message is entirely done by software
4. Clear FIFO	This procedure clears the FIFO in order to be ready to receive a new message, or in case of error.	Write <code>SLIMBUS_SMR_INFO[2] RECEIVED_MESSAGE = 1</code>
<b>Interrupt subroutine</b>		
5. Check and process events	<ol style="list-style-type: none"> <li>1. Clear the corresponding status bit</li> <li>2. Check the pending event by polling the related information register's flags.</li> <li>3. Process the event as required. For more information see <a href="#">Section 23.9.4.12.6</a> SLIMbus Shared Message Channel Receive ISRs</li> <li>4. When needed and allowed, clear the information register</li> </ol>	<ol style="list-style-type: none"> <li>1. Write <code>SLIMBUS_CMP_IRQSTATUS[3] SMR_INFO = 1</code></li> <li>2. Poll <code>SLIMBUS_SMR_INFO[4:0]</code></li> <li>3. Process the event as required.</li> <li>4. Write <code>SLIMBUS_SMR_INFO[4:0] = 0x1F</code></li> </ol>

**NOTE:** For information about all SLIMbus events see [Section 23.9.4.12.2](#) Possible interrupts.

### 23.9.5.1.3.5 Receiving data

This procedure reads data word received in FIFO from a SLIMbus device.

Interrupts must be enabled in order to generate interrupt, when data is ready for reading from FIFO. More about enabling interrupts see in [Section 23.9.5.1.2.2](#) SLIMbus interrupts configuration.

Data receive channel(s) must be configured to generate DMA requests, when DMA mode is used for data transfer. See [Section 23.9.5.1.2.3](#) SLIMbus DMA configuration.

**Table 23-684. Data word receiving**

Step	Register / Bit Field / Programming Model	Value
Check FIFO level	<code>SLIMBUS_DCR_INFO_j[3] HILEVEL</code>	=0x1
Read data word from FIFO	<code>SLIMBUS_DCR_DATA_j</code>	See <sup>(1)</sup>

<sup>(1)</sup> FIFO data word size varies between 1 and 8 slots (4 and 32bits). See [Table 23-655](#), Examples of AUX + DATA mapping in 32-bit read/write accesses.

### 23.9.5.1.3.6 Transmitting data

This procedure loads data word to FIFO for transmitting to a SLIMbus device.

Interrupts must be enabled in order to generate interrupt, when FIFO is ready for more data loading. More about enabling interrupts see in [Section 23.9.5.1.2.2](#) SLIMbus interrupts configuration.

Data transmit channel(s) must be configured to generate DMA requests, when DMA mode is used for data transfer. See [Section 23.9.5.1.2.3](#) SLIMbus DMA configuration.

**Table 23-685. Data word transmitting**

Step	Register / Bit Field / Programming Model	Value
Check FIFO level	<code>SLIMBUS_DCT_INFO_j[3] LOLEVEL</code>	=0x1
Write data word to FIFO	<code>SLIMBUS_DCT_DATA_j</code>	See <sup>(1)</sup>

<sup>(1)</sup> FIFO data word size varies between 1 and 8 slots (4 and 32bits). See [Table 23-655](#), Examples of AUX + DATA mapping in 32-bit read/write accesses.

#### **23.9.5.1.4 Event handling**

For Information about all SLIMbus events handling refer to [Section 23.9.4.12.1 Interrupt Requests](#).

## 23.9.6 SLIMbus Register Manual

### 23.9.6.1 SLIMbus Register Overview

The registers described in this section are prefixed with one of the following:

- **CMP:** Component- (that is, module) level control and status.
- **SMT:** Shared Messages Transmit: All messages transmitted to the serial SLIMbus interface. This resource is shared by all devices within the component (all devices can transmit messages).
- **SMR:** Shared Messages Receive: All messages received from the serial SLIMbus interface. This resource is shared by all devices within the component (all devices can receive messages).
- **FL:** Frame Layer status and control. The frame layer is the hardware-implemented protocol layer located just above the physical layer, and shared by all devices of a component.
- **FR:** Framer device-specific status and control. The framer device is one of the component's devices (logical entities of the SLIMbus); exactly one framer device may optionally be implemented in each SLIMbus component. Note that the framer device is not always active (in which case the related registers aren't used either), and that some of the framer's control and status is shared with the (always-present, always-active) interface device.
- **DEV:** Device control and status. The same register structure is repeated as many times as there are devices supported by the component (that is, the module), including the (compulsory) interface device, the framer device (optional), the manager device (optional), and the generic devices (optional, one or several instances).
- **DCT:** Data Channel Transmit: The same register structure is repeated as many times as there are transmit data channels supported, that is, FIFOs and associated logic. Devices (typically generic devices) are associated to a data channel for the transmissions of data towards the SLIMbus serial interface.
- **DCR:** Data Channel Receive: The same register structure is repeated as many times as there are receive data channels supported, that is, FIFOs and associated logic. Devices (typically generic devices) are associated to a data channel for the reception of data from the SLIMbus serial interface.

### 23.9.6.2 SLIMbus Instance Summary

Table 23-686 shows the base address and address space for the SLIMbus module instances.

**Table 23-686. SLIMbus Instance Summary**

Module Name	Base Address L3 Interconnect	Base Address Cortex-A9 Private Access	Base Address DSP Private Access	Size
SLIMBUS1	0x4902 C000	0x4012 C000	0x2 C000	4 KB
SLIMBUS2	0x4807 6000	-	-	4 KB

**NOTE:** Private Access is an access which is not using the L3/L4 interconnects.

### 23.9.6.3 SLIMbus Registers

#### 23.9.6.3.1 SLIMBUS1 Register Summary

**Table 23-687. SLIMBUS1 Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address L3 Interconnect	Physical Address Cortex-A9 Private Access	Physical Address DSP Private Access
<a href="#">SLIMBUS_CMP_REVISION</a>	R	32	0x0000 0000	0x4902 C000	0x4012 C000	0x2 C000

31:0	REVISION	Revision Number	R	0x---- ---- <sup>(1)</sup>

<sup>(1)</sup> TI internal data.

**Table 23-690. Register Call Summary for Register SLIMBUS\_CMP\_REVISION**

Serial Low-Power Inter-Chip Media Bus Controller

- [SLIMBUS1 Register Summary: \[0\]](#)
- [SLIMBUS2 Register Summary: \[1\]](#)

**Table 23-691. SLIMBUS\_CMP\_HWINFO**

<b>Address Offset</b>	0x0000 0004		
<b>Physical Address</b>	See	<b>Instance</b>	SLIMBUS1 SLIMBUS2
	<a href="#">Table 23-687</a> to <a href="#">Table 23-688</a>		
<b>Description</b>	Those read-only, hardcoded fields display the values of the eponymous hardware configuration depending on module instantiation - SLIMBUS1 or SLIMBUS2.		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DEV		TDC		RDC		RRSZ				TRSZ				PSZ																	

Bits	Field Name	Description	Type	Reset
31:28	DEV	Device count: number of devices supported by the component, most notably through the automatically reception of the messages addressed to them. Sets the number of instances of the "DEV_XYZ" registers.	R	0x7
27:24	TDC	Transmit Data agent Count: Number of transmit hardware data agents (FIFO and associated logic) Sets the number of instances of the "DCT_XYZ" registers.	R	See <a href="#">Table 23-693</a>
23:20	RDC	Receive Data agent Count: Number of receive hardware data agents (FIFO and associated logic) Sets the number of instances of the "DCR_XYZ" registers.	R	See <a href="#">Table 23-693</a>
19:12	RRSZ	Size of receive FIFO RAM, in 32-bit words. RX message FIFO and all RX data FIFOs map to that shared RAM.	R	See <a href="#">Table 23-693</a>
11:4	TRSZ	Size of transmit FIFO RAM, in 32-bit words. TX message FIFO and all TX data FIFOs map to that shared RAM.	R	See <a href="#">Table 23-693</a>

Bits	Field Name	Description	Type	Reset
3:0	PSZ	Size of (both TX and RX) FIFO segment word pointers, in bits. Determines the maximum number of (variable-sized) segment words a data agent FIFO can contain. Sets the width of FIFO control and status fields: size, threshold, level.	R	0x8

**Table 23-694. SLIMBUS\_CMP\_SYSCONFIG**

<b>Address Offset</b>	0x0000 0010		
<b>Physical Address</b>	See	<b>Instance</b>	SLIMBUS1 SLIMBUS2
<b>Description</b>	This register allows controlling various parameters of the interconnect interface		
<b>Type</b>	RW		

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x000000
8	AUTOGATINGDISABLE	Control of the internal clock autogating for safety / debug only. No impact on module functionality, only on dynamic power. 0x0: Internal clocks are gated off when unused, power is optimized. 0x1: Internal clocks are free-running, maximum dynamic power.	RW	0
7:4	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
3:2	IDLEMODE	<p>Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state.</p> <p>0x0: Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, that is, regardless of the IP module's internal requirements. Backup mode, for debug only.</p> <p>0x1: No-idle mode: local target never enters idle state. Backup mode, for debug only.</p> <p>0x3: Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state. Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented.</p> <p>0x2: Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wakeup events.</p>	RW	0x2
1	RESERVED		R	0
0	SOFTRESET	<p>Software reset. (Optional)</p> <p>Write 0x0: No action</p> <p>Write 0x1: Initiate software reset</p> <p>Read 0x1: Reset (software or other) ongoing</p> <p>Read 0x0: Reset done, no pending action</p>	RW	0

## 23.10 MIPI-HSI

This section describes the Mobile Industry Processor Interface (MIPI) high-speed synchronous serial interface (HSI).

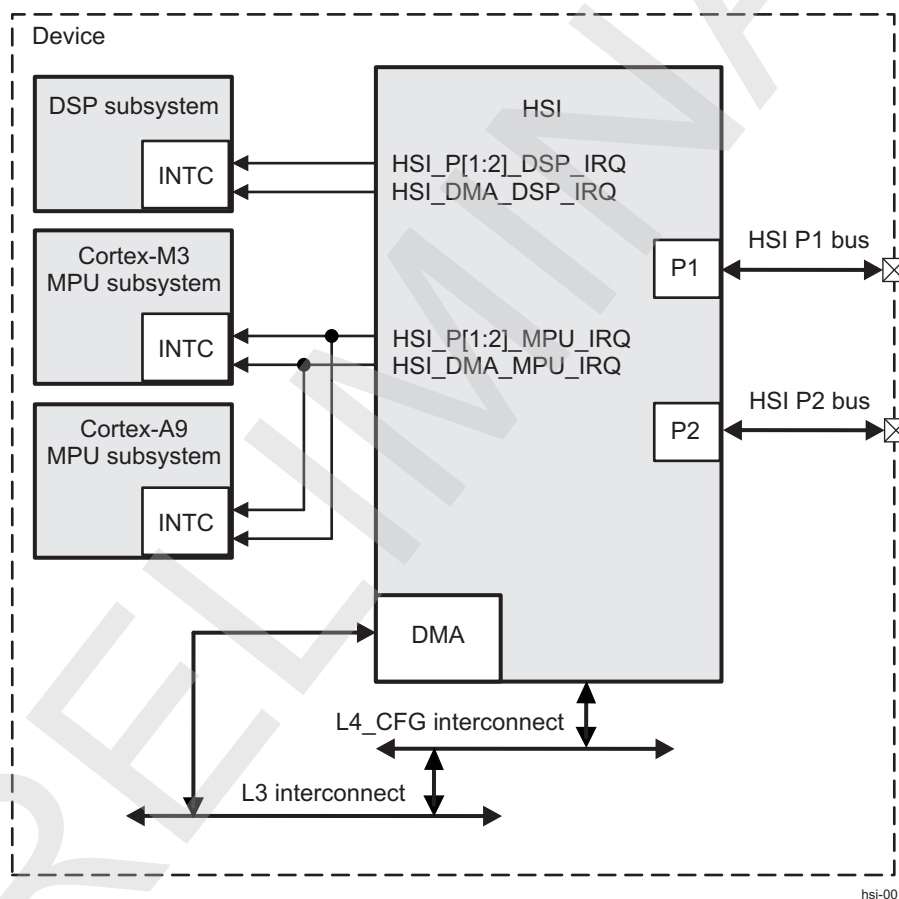

### 23.10.1 HSI Overview

The MIPI high-speed synchronous serial interface (HSI) module is a multichannel and full-duplex serial communications interface, composed of two transmitters (HST) in charge of the transmitted information and two receivers (HSR) in charge of the received information, sharing a 16-channel direct memory access (DMA).

The HSI peripheral is used typically to enable the device to exchange information with an external cellular modem.

Figure 23-220 shows an overview of the HSI module.

**Figure 23-220. HSI Overview**

hsi-001

HSI supports the following features:

- Full duplex
- No static clock matching
- Interface speed up to 192 Mbps on transmitter and up to 225 Mbps on receiver
- Transmission speed and operation mode dynamically configurable
- Logical channels:
  - Up to 16 logical channels on receiver
  - Up to 16 logical channels on transmitter
- One 32-request DMA engine:
  - 16 transmit + 16 receive requests from HSI port

- 16 logical DMA channels
- Interrupt requests:
  - Three to each processor subsystem (two from HSI port, one from DMA)

### 23.10.2 HSI Environment

This section describes the HSI application fields from an environment point of view (external connections).

#### 23.10.2.1 HSI Signals

Table 23-786 describes the HSI module I/O signals.

**Table 23-786. HSI I/O Signals**

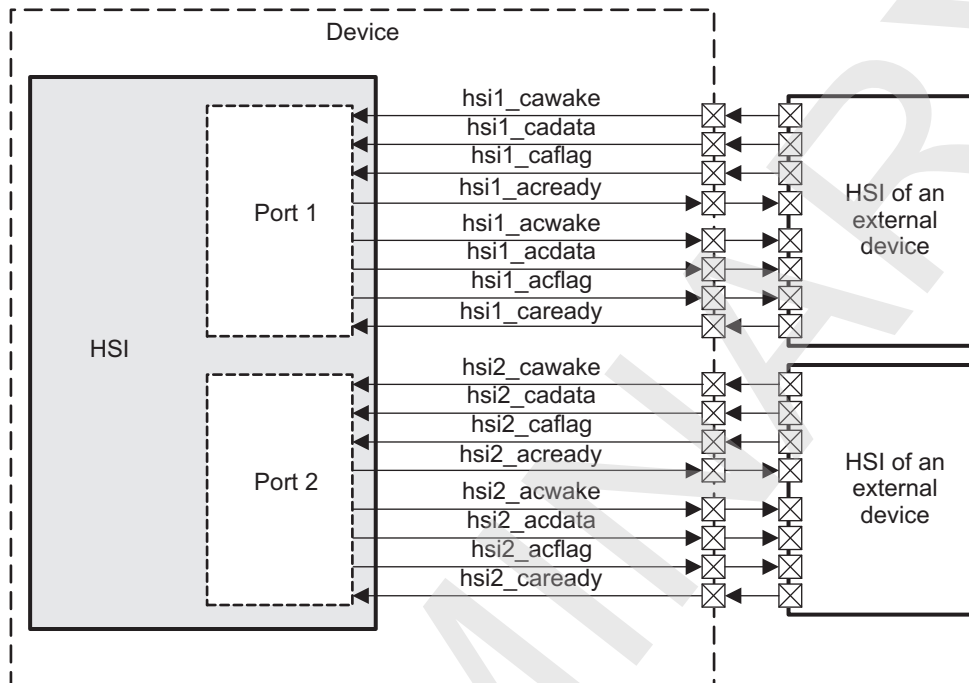

Pin Name	I/O <sup>(1)</sup>	Description	Reset Value
hsi1_cawake	I	HSI port 1 wake-up signal from an external serial transmitter	HiZ
hsi1_cadata	I	HSI port 1 receiver data from an external transmitter	HiZ
hsi1_caflag	I	HSI port 1 receiver flag from an external transmitter	HiZ
hsi1_acready	O	HSI port 1 synchronization signal to an external transmitter	1
hsi1_acwake	O	HSI port 1 wake-up signal to an external serial receiver	0
hsi1_acdata	O	HSI port 1 transmission data (level transmission signaling) to an external receiver	0
hsi1_acflag	O	HSI port 1 transmission flag (bit transition signaling) to an external receiver	1
hsi1_caready	I	HSI port 1 synchronization signal from an external receiver	HiZ
hsi2_cawake	I	HSI port 2 wake-up signal from an external serial transmitter	HiZ
hsi2_cadata	I	HSI port 2 receiver data from an external transmitter	HiZ
hsi2_caflag	I	HSI port 2 receiver flag from an external transmitter	HiZ
hsi2_acready	O	HSI port 2 synchronization signal to an external transmitter	HiZ
hsi2_acwake	O	HSI port 2 wake-up signal to an external serial receiver	HiZ
hsi2_acdata	O	HSI port 2 transmission data (level transmission signaling) to an external receiver	HiZ
hsi2_acflag	O	HSI port 2 transmission flag (bit transition signaling) to an external receiver	HiZ
hsi2_caready	I	HSI port 2 synchronization signal from an external receiver	HiZ

<sup>(1)</sup> I = input; O = output

### 23.10.2.2 HSI Typical Application

Figure 23-221 shows the HSI typical application.

**Figure 23-221. HSI Typical Application**

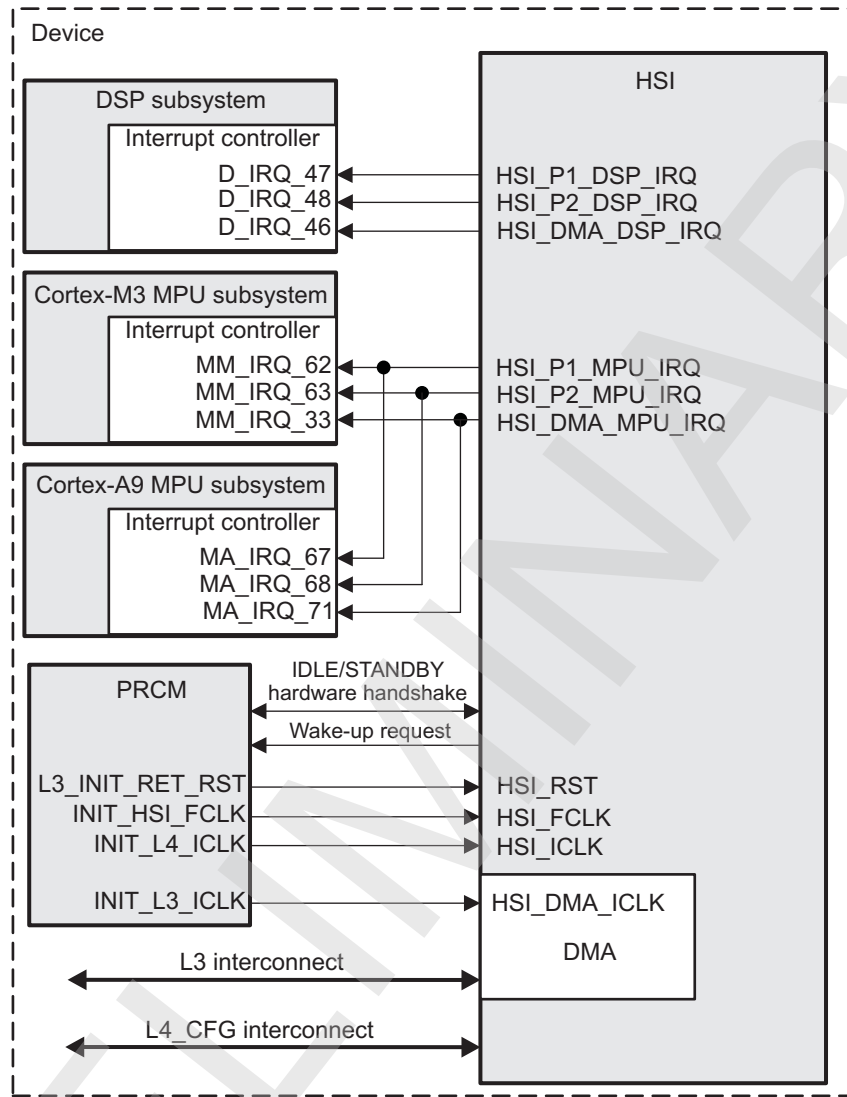

hsi-002

### 23.10.3 HSI Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 23-222 shows the HSI module integration.

Figure 23-222. HSI Integration

hsi-003

**NOTE:** For more information about the IDLE/STANDBY hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

The following interrupt lines - HSI\_P[1:2]\_MPU\_IRQ and HSI\_DMA\_MPU\_IRQ - are shared between Cortex™-A9 MPU and Cortex™-M3 MPU interrupt controllers (INTCs). It is strongly recommended each interrupt source be unmasked in only one interrupt controller at a time.

[Table 23-787](#) through [Table 23-789](#) summarize the integration of the module in the device.

Table 23-787. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-up Capability	Interconnect
HSI	PD_L3_INIT	NA	L3 L4_CFG

**Table 23-788. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
HSI	HSI_FCLK	INIT_HSI_FCLK	PRCM	HSI module functional clock
	HSI_ICLK	INIT_L4_ICLK	PRCM	HSI module interface clock
	HSI_DMA_ICLK	INIT_L3_ICLK	PRCM	HSI DMA engine interface clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
HSI	HSI_RST	L3_INIT_RET_RST	PRCM	HSI module asynchronous reset

**Table 23-789. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
HSI	HSI_DMA_MPU_IRQ <sup>(1)</sup>	MM_IRQ_33	Cortex-M3	HSI DMA engine MPU request
	HSI_P1_MPU_IRQ <sup>(1)</sup>	MM_IRQ_62	Cortex-M3	HSI MPU request - Port 1
	HSI_P2_MPU_IRQ <sup>(1)</sup>	MM_IRQ_63	Cortex-M3	HSI MPU request - Port 2
	HSI_DMA_DSP_IRQ	D_IRQ_46	DSP	HSI DMA engine DSP request

	HSI_P1_MPU_IRQ <sup>(1)</sup>	MA_IRQ_67	Cortex-A9	HSI MPU request - Port 1
	HSI_P2_MPU_IRQ <sup>(1)</sup>	MA_IRQ_68	Cortex-A9	HSI MPU request - Port 2
No DMA Requests				

<sup>(1)</sup> Interrupts shared between Cortex-A9 MPU INTC and Cortex-M3 MPU INTC

**NOTE:** For a description of interrupt sources, see [Section 23.10.4.5, Interrupt Requests](#)

### 23.10.4 HSI Functional Description

---

**NOTE:** In the functional description section, the following common internal signal names are used for the corresponding external HSI signals (for simplification):

- WAKE: hsi1\_cawake, hsi1\_acwake, hsi2\_cawake, and hsi2\_acwake
  - DATA: hsi1\_cadata, hsi1\_acdata, hsi2\_cadata, and hsi2\_acdata
  - FLAG: hsi1\_caflag, hsi1\_acflag, hsi2\_caflag, and hsi2\_acflag
  - READY: hsi1\_acready, hsi1\_caready, hsi2\_acready, and hsi2\_caready
- 

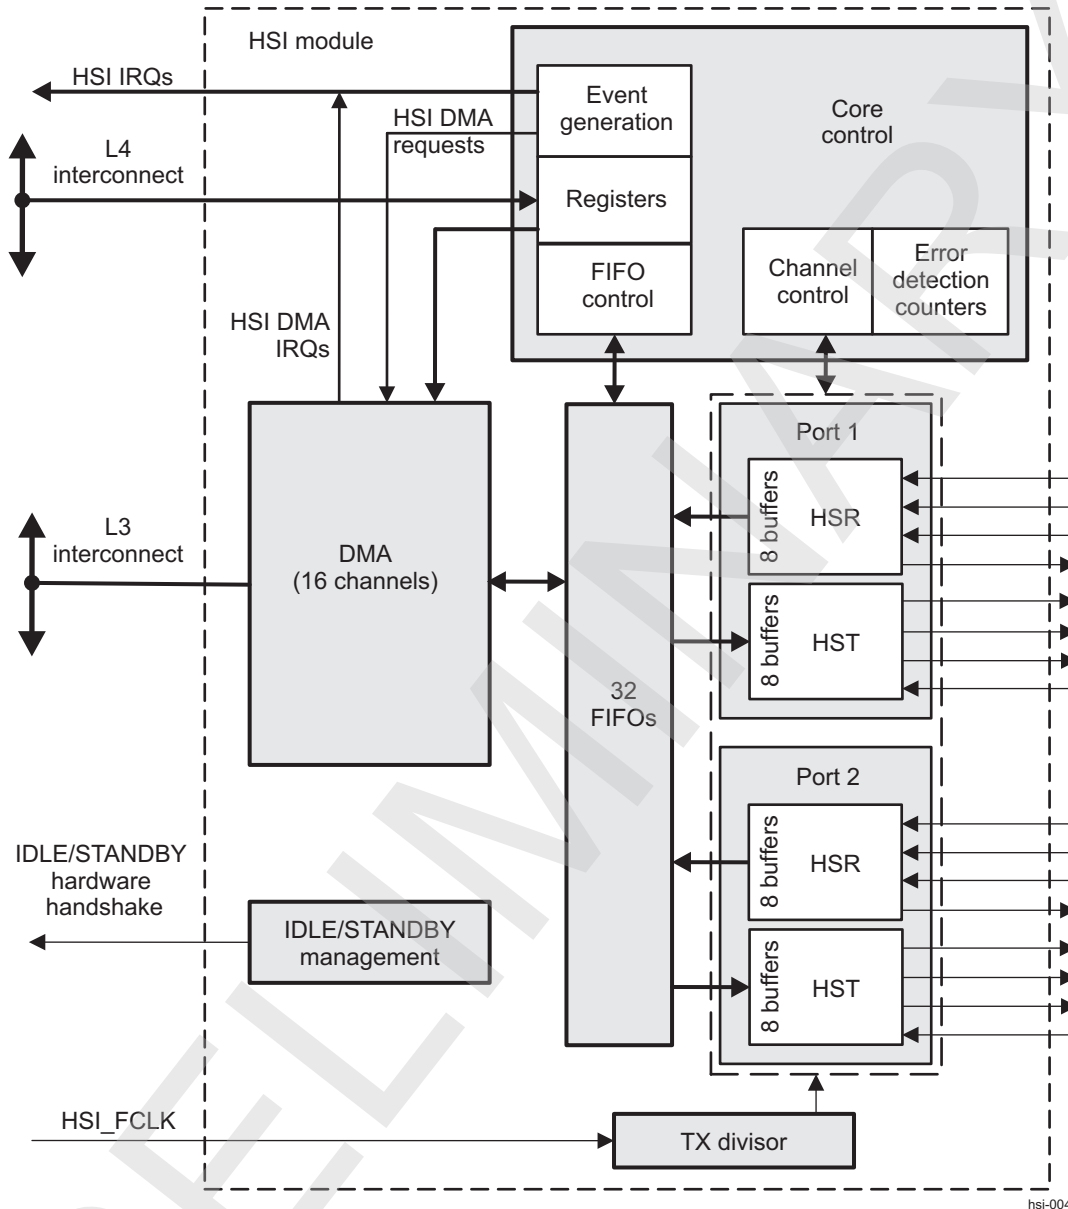

#### 23.10.4.1 Block Diagram

The HSI controller is a subsystem built around two full-duplex multichannel synchronous serial interfaces. It contains a 16-bidirectional-logical-channel DMA in charge of handling data transfers between HSI modules and the L3 interconnect. Also interrupt access to data is available.

**NOTE:** Transmit data cannot be read back and received data cannot be written in DMA and IRQ based transfers.

---

Figure 23-223 shows most HSI module features.

**Figure 23-223. HSI Controller Architecture Overview**

**NOTE:** There is a bypass path in the DMA, which allows a processor (MPU or DSP) to retrieve or provide data received or to be transmitted on an interrupt triggered access, when the DMA is not enabled.

### 23.10.4.2 Clock Configuration

The HSI module has four fully asynchronous clock domains:

- Interface clock domain
- Functional clock domain
- Receive clock domain on port 1
- Receive clock domain on port 2

### 23.10.4.2.1 Interface Clock Domain

The following clocks are part of the interface clock domain:

- HSI\_DMA\_ICLK runs the interface master port (L3). This clock is used for DMA master access to the L3 interconnect and also serves as DMA functional clock.
- HSI\_ICLK runs the interface slave port (L4). This clock is used for configuration of the module and is also used to transmit/receive data through register access in an interrupt based manner.

### 23.10.4.2.2 Functional Clock Domain

The functional clock (HSI\_FCLK) runs the transmitter/receiver logic.

#### 23.10.4.2.2.1 Transmit Clock

The transmit clock is obtained from the functional clock and is used to generate transmitter DATA and FLAG lines, according to the standard. Namely, the DATA line shall always reflect the transmitted bit value, whereas the FLAG line shall provide a transition (0->1, or 1->0) when current DATA value is the same as the previous one.

The transmit data rate is programmable through the [HST\\_DIVISOR\\_Pp\[7:0\]](#) TX\_RATE\_DIV\_VAL bit field.

$$\text{Transmit clock} = \text{HSI\_FCLK} / (\text{TX\_RATE\_DIV\_VAL} + 1).$$

#### 23.10.4.2.2.2 Receive Error Detection Counters Clocks

The functional clock is also used to obtain clocks for Receive Error Counters, which are independently divided versions of the functional clock. Division is set by software through the [HSR\\_DIVISOR\\_Pp\[7:0\]](#) RX\_RATE\_DIV\_VAL bit field, which sets the bit rate clock for frame time-out counter. This clock is further divided to generate an edge per frame to be sent to the frame burst counter.

### 23.10.4.2.3 Receive Clock Domain (Port 1 and Port 2)

The RX clock is retrieved from the DATA and FLAG signals available on the serial interface. A self-clocked source synchronous receiver implementation is done as follows: simple XOR of the DATA and FLAG signals recovers a signal displaying a transition on every bit time. From this signal, two clocks are generated with appropriate phase, which can recover bit values, by sampling the DATA line, where the transmitted bit is always available.

#### 23.10.4.2.3.1 Receiver Clock Recovery

The HSI module uses a delay-locked loop (DLL) to delay the received and recovered clock to produce a delayed version. These clocks are then used to sample the DATA line, not to reconstruct a data flow, but to store received bits on some registers, to load them on receive FIFO as soon as 32 bits (that is, a full word) have arrived.

The DLL module is integrated in the HSR block. The usage of the DLL module is controlled by [HSR\\_DLL\[1\]](#)DLL\_NOT\_BYPASSED bit field. The configurable delay is set through a 10-bit master\_slave\_code value, programmed through the [HSR\\_DLL\[17:8\]](#) INCO bit field. The actual value is:

$$\text{master\_slave\_code} = \text{requested delay} / \text{fine\_delay\_step}.$$

---

**NOTE:** If there is a need to utilize its functionality, care shall be taken while reconfiguring its delay value to prevent invalid clock edges in the RX

---

Software may need to update master\_slave\_code when different OPP are run. In this case, the delay suffers significant variation, and the programming code may need to change, to get the same delay as before. To perform such operation, before operating performance point (OPP) can be changed, software must write 1 on the [HSR\\_DLL\[0\]](#) COCHRE (Code CHange REquest) bit field. Receiver ends the reception of the current frame and drops READY to 0 to prevent transmission of more frames. In case of pipelined

flow, this can take more than one frame time. When READY is 0, the hardware writes 1 on [HSR\\_DLL\[4\] COCHGR](#) (COde CHange GRant) and only at this point the software can program DLL with a the new master\_slave\_code, written in [HSR\\_DLL\[17:8\] INCO](#) (INput COde) at the end of operations, then the [HSR\\_DLL\[0\] COCHRE](#) and [HSR\\_DLL\[4\] COCHGR](#) bit fields are set again to 0. [HSR\\_DLL\[0\] COCHRE](#) are cleared by software, and at this point hardware clears the [HSR\\_DLL\[4\] COCHGR](#) bit.

### 23.10.4.3 Software Reset

The HSI module can be reset by software through the [HSI\\_SYSCONFIG\[1\] SOFTRESET](#) bit. Setting this bit to 1 enables an active global software reset that is functionally equivalent to a hardware reset. The [HSI\\_SYSSTATUS\[0\] RESETDONE](#) bit indicates that the software reset is complete when its value is set to 1. The software must ensure that the software reset completes before doing HSI operations.

The DMA engine can be independently reset by software through the [DMA\\_GRST\[0\] SWRESET](#) bit. Setting this bit to 1 resets the DMA registers and logic. This bit is automatically cleared when the DMA reset completes.

### 23.10.4.4 Power Management

[Table 23-790](#) describes power-management features available for the HSI module.

#### NOTE:

- For descriptions of IdleMode and StandbyMode features, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**Table 23-790. Local Power-Management Features**

Feature	Registers	Description
Clock auto gating	<a href="#">HSI_SYSCONFIG[0] AUTOIDLE</a>	This bit allows a local power optimization inside the module, by gating the HSI_ICLK clock upon the interface activity.
	<a href="#">DMA_GCR[3] AUTOGATING</a>	This bit allows a local power optimization inside the module, by gating the HSI_DMA_ICLK clock upon the interface activity.
Slave idle modes	<a href="#">HSI_SYSCONFIG[4:3] SIDLEMODE</a>	Force-idle, no-idle, smart-idle, and smart-idle wakeup capable modes are available.
Master standby modes	<a href="#">HSI_SYSCONFIG[13:12] MIDLEMODE</a>	Force-standby, no-standby, smart-standby and smart-standby wakeup modes are available.

#### 23.10.4.4.1 HSI Module Power Management Modes

##### 23.10.4.4.1.1 Standby

When asserted, this signal informs the PRCM module that HSI is quiet and does not generate any traffic on the interconnect.

The HSI module supports four STANDBY handshake modes, selected through the [HSI\\_SYSCONFIG\[13:12\] MIDLEMODE](#) bit field:

- Force-standby (0x0): Selecting this mode asserts the standby signal unconditionally of the HSI activity. Software must ensure that HSI is disabled and does not generate any activity before activating this mode.
- No-standby (0x1): Standby signal is never asserted.
- Smart-standby (0x2): Standby signal is asserted when internal HSI DMA does not generate activity anymore (namely, upon DMA idle acknowledge signal assertion).
- Smart-standby wakeup (0x3): Standby signal is asserted when internal HSI DMA does not generate activity anymore (namely, upon DMA idle acknowledge signal assertion). It can also generate a wake-up request.

**23.10.4.4.1.2 Idle**

The PRCM module asserts an IDLE request signal when it requires the HSI slave port to be idled. Any access to this port after the idle request signal has been asserted generates an error.

The HSI module supports four IDLE handshake modes, selected through the [HSI\\_SYSCONFIG\[4:3\] SIDLEMODE](#) bit field:

- Force-idle (0x0): An idle request is acknowledged unconditionally.
- No-idle (0x1): An idle request is never acknowledged.
- Smart-idle (0x2): Acknowledgement to an idle request is given based on the internal HSI module activity.
- Smart-idle Wakeup (0x3): Acknowledgement to an IDLE request is given based on the internal HSI module activity. Additionally, when in this mode, the HSI module is allowed to generate a wake-up request.

**23.10.4.4.1.3 Auto-idle**

The HSI module provides an auto-idle option for the interface clock domain. Auto-idle mode is enabled by writing 1 to [HSI\\_SYSCONFIG\[0\] AUTOIDLE](#) and/or [DMA\\_GCR\[3\] AUTOGATING](#) bits. When this mode is enabled and there is no activity on the interconnect interface, the interface clock is disabled internally to the module to reduce power consumption. When there is new activity on the interconnect interface, the interface clock is restarted without any latency penalty.

**23.10.4.4.1.4 DMA Engine Switch Off Mode**

DMA interface clock (HSI\_DMA\_ICLK) can be switched off by setting the [DMA\\_GCR\[0\] SWITCH\\_OFF](#) bit field to 1. DMA clock activity is then cut off. Software must make sure that ongoing transitions are completed before cutting off clocks. Once the DMA is switched off, only access through configuration port to reset this bit is possible.

**23.10.4.5 Interrupt Requests**

[Table 23-791](#) lists the event flags, and their mask, that can cause module interrupts.

**Table 23-791. Events**

Event Flag	Event Mask	Map to	Description
<a href="#">HSI_Pp_M_IRQrU_STATUS[26]</a> HSR_WAKE	<a href="#">HSI_Pp_M_IRQrU_ENABLE[26]</a> HSR_WAKE	HSI_P1_MPU_IRQ HSI_P2_MPU_IRQ	Wake detected on any channel 8..15.

### 23.10.4.5.1 Interrupts

The HSI module outputs six interrupt signals (for more information, see [Section 23.10.3, MIPI HSI Integration](#)). All the interrupts are active-high level-sensitive. Each interrupt line is activated by a set of individual sources. All interrupt sources can individually be enabled and disabled.

For each interrupt, 2 status bits and 2 mask bits are provided, allowing independent masking for the different processors (that is, 1 status bit and 1 mask bit for the MPU [Cortex-A9 or Cortex-M3] interrupts, and 1 status bit and 1 mask bit for the DSP interrupts).

Interrupts in the HSI module are intended to:

- Signal any error condition in reception
- Support the WAKE condition detection
- Support the BREAK condition detection
- Warn of DMA transfer status or problems
- Signal to processors when to read received data and to write data to transmit

DMA has only 16 channels, so 16 RX FIFO and 16 TX FIFO are managed by a mix of DMA driven and interrupt driven read/write policies.

#### **23.10.4.5.1.1 HSI Interrupt Generation**

Five types of interrupt events can be generated by each HSI port:

- Transmit FIFO not full: occurs when TX FIFO is not full, so data can be written for transmission.
- Received data available: occurs when one data frame has been received and is available on the RX FIFO for reading.
- Overrun: occurs when data overrun is detected on HSI port  $p$  channel  $i$
- Error: any error defined by the MIPI HSI protocol activates this source of interrupt if this source is enabled.
- Break condition detected: occurs upon reception of a continuous string of 0s, that exceeds those possible in any FRAME mode frame (data + header). Because FRAME mode always put a 1 before any frame, the maximum number of 0s occurring during normal transmission is clearly 32 plus the base 2 logarithm of channels used. Hardware works out this number based on register information on channels and receive mode, sets the `HSR_BREAK_Pp[0] BREAK_VAL` bit to 1, and issues an interrupt if this source is enabled.

All the events are cleared by software, upon writing 1 on the corresponding register bit. Writing 0 has no effect.

#### **23.10.4.5.1.2 DMA Interrupt Generation**

Three types of interrupt events can be generated by each DMA channel:

- End of Block: Enabled through the `DMA_CSR_CCIR_i[5] BLOCK_IE` bit, it occurs when the last element of the transfer has been written into destination. The `DMA_CEN_i[15:0] SIZE` bit field defines the number of elements in a block.
- Half Block: Enabled through the `DMA_CSR_CCIR_i[2] HALF_IE` bit, it occurs when a half of the elements have been written into destination.
- Time-out error: Enabled through the `DMA_CSR_CCIR_i[0] TOU_IE` bit, it occurs when destination slave answers by an error code.

All interrupt events are generated on the same logical channel dedicated interrupt line. When an interrupt is issued by a logical channel, its `DMA_CSR_CCIR_i` status register is set to record the interrupt cause, if the interrupt event bit is enabled in the relevant `DMA_CSR_CCIR_i` register. The processor interrupt service routine can read this channel status register to identify the sources of the interrupt. The status bits are automatically cleared after they are read by the processor, unless it is an emulation read.

There are two classes of DMA interrupt events:

- Error events: Errors during the transfer
- Status events: DMA transfer status, such as end of block or half-block

The DMA manages the two classes differently.

For an enabled error event, the following sequence occurs:

1. The appropriate bit in the `DMA_CSR_CCIR_i` register is set.
2. An interrupt is generated.
3. The ports are released.
4. Currently active logical channel is disabled and must be reprogrammed.
5. Other channels are not affected, and a new channel can get over, according to programmed priorities.

For an enabled status event, the following sequence occurs:

1. The appropriate bit in the `DMA_CSR_CCIR_i` register is set.
2. An interrupt is generated.
3. A new interrupt cannot be generated until the status register is read and thereby cleared.

All the events are cleared by software, upon writing 1 on the corresponding interrupt status register (`HSI_DMA_M_IRQSTATUS` or `HSI_DMA_D_IRQSTATUS`). Writing 0 has no effect.

### 23.10.4.6 DMA Module

#### 23.10.4.6.1 DMA Overview

The DMA module transfers data between the HSI interfaces and the device on-chip memories. The DMA module supports 16 logical channels and is a dual-port initiator (peripheral port/memory port) with one slave port for configuration. The memory port provides an interface to the memory space and the peripheral port provides an interface to the HSI interfaces. In the HSI controller, the L4\_CFG port accesses can be routed directly to the HSI interfaces. This is done by setting the DMA in bypass mode to route the DMA slave port to the DMA peripheral port.

DMA features:

- One target port, for configuration
- 16 logical channels:  $n$  for transmission and  $16-n$  for reception
- One initiator port, for transfer to/from memory
- One port to/from LCH memory: this memory holds some registers
- 32-bit data handling only
- Constant addressing mode on peripheral port/FIFO
- Post-increment addressing mode with burst support on memory port
- Software enabling
- Hardware activation of data transfer on peripheral port
- Logical channels interleaving with only few-cycles-latency
- Fixed allocation of memory and peripheral port to a logical channel
- LCH first-come-first-served + fixed priority arbitration
- Low-power operation (hardware control for clock domains activity)
- Software reset

#### 23.10.4.6.2 DMA Memories

DMA channel register memory is managed by the DMA. Only the DMA interfaces this memory. A processor must program the DMA registers included in this memory.

The DMA has an access to 16 dual port FIFOs 8 x 32 bits for reception and 16 dual port FIFOs 8 x 32 bits for transmission. They are provided in the form of two separate memories.

#### 23.10.4.6.3 DMA Basic Operation Outline

DMA write and read operations are helped by tags, to manage possibly disorderly answers. Posted or nonposted operations are possible. In any case, the interconnect always manages them as nonposted. This is consistent with DMA operations, that need to know; (for example, if main memory write was successful). If not, the error response from L3 interconnect slave produces a DMA error and the corresponding interrupt. DMA addressing of FIFO memories will always be on a constant address, corresponding to 1 of the 16 `HST_BUFFER_Pp_CHN_i` (or `HSR_BUFFER_Pp_CHN_i`) registers.

These registers are associated to the 16 FIFOs and the naming reflects only the reset value of the association FIFO - HSI logical channel. So at reset, the FIFO addressed on register `HSR_BUFFER_P2_CHN_4` is associated to the fourth logical channel of the second port. Nevertheless, software can change this mapping and associate the same FIFO (for example, to the seventh channel of the first port). This mapping is performed by software through the `HST_MAPPINGf[4:1] CH_NUMBER` or `HSR_MAPPINGf[4:1] CH_NUMBER` bit fields.

#### 23.10.4.6.4 DMA Configuration

Before performing a DMA transfer, the following DMA registers must be configured:

- `DMA_CCR_CSDP_i` - sets source and destination parameters and channel control
  - `DMA_CCR_CSDP_i[15:14] DST_BURST_EN` - destination burst enable (0x0 and 0x1 - single access; 0x2 - burst 4 x 32 bits; 0x3 - burst 8 x 32 bits);
  - `DMA_CCR_CSDP_i[12:9] DST` - transfer destination (0x8 - transfer to memory port; 0x9 - transfer

- to peripheral port);
- [DMA\\_CCR\\_CSDP\\_i\[8:7\]](#) SRC\_BURST\_EN - source burst enable (0x0 and 0x1 - single access; 0x2 - burst 4 x 32 bits; 0x3 - burst 8 x 32 bits);
  - [DMA\\_CCR\\_CSDP\\_i\[5:2\]](#) SRC - transfer source (0x8 - transfer from memory port; 0x9 - transfer from peripheral port);
  - [DMA\\_CCR\\_CSDP\\_i\[31:30\]](#) DST\_ADD\_MODE - destination addressing mode (0x0 - constant address mode; 0x1 - post-incremented address mode);
  - [DMA\\_CCR\\_CSDP\\_i\[29:28\]](#) SRC\_ADD\_MODE - source addressing mode (0x0 - constant address mode; 0x1 - post-incremented address mode);
  - [DMA\\_CSR\\_CCIR\\_i](#) - enables DMA sources of interrupt events.
  - [DMA\\_CSSA\\_i\[31:0\]](#) ADDR - stores 32 bits of the source address
  - [DMA\\_CDSA\\_i\[31:0\]](#) ADDR - stores 32 bits of the destination address
  - [DMA\\_CEN\\_i\[31:0\]](#) SIZE - defines the number of elements in a block. Maximum number of elements is 65535.

To start a DMA transfer, the DMA channel to be used must be enabled by writing 1 to [DMA\\_CCR\\_CSDP\\_i\[23\]](#) ENABLE bit. Once the DMA transfer is finished, the [DMA\\_CCR\\_CSDP\\_i\[23\]](#) ENABLE bit is automatically reset by hardware.

[DMA\\_CDAC\\_CSAC\\_i\[15:0\]](#) ADDRESS\_CSAC (or [DMA\\_CDAC\\_CSAC\\_i\[31:15\]](#) ADDRESS\_CDAC) bit field can be used to monitor the progress of a DMA transfer on channel source (or destination). It is a snapshot of source (or destination) address generated by channel counter. It is incremented on each access made on channels.

### 23.10.4.7 HSR Module

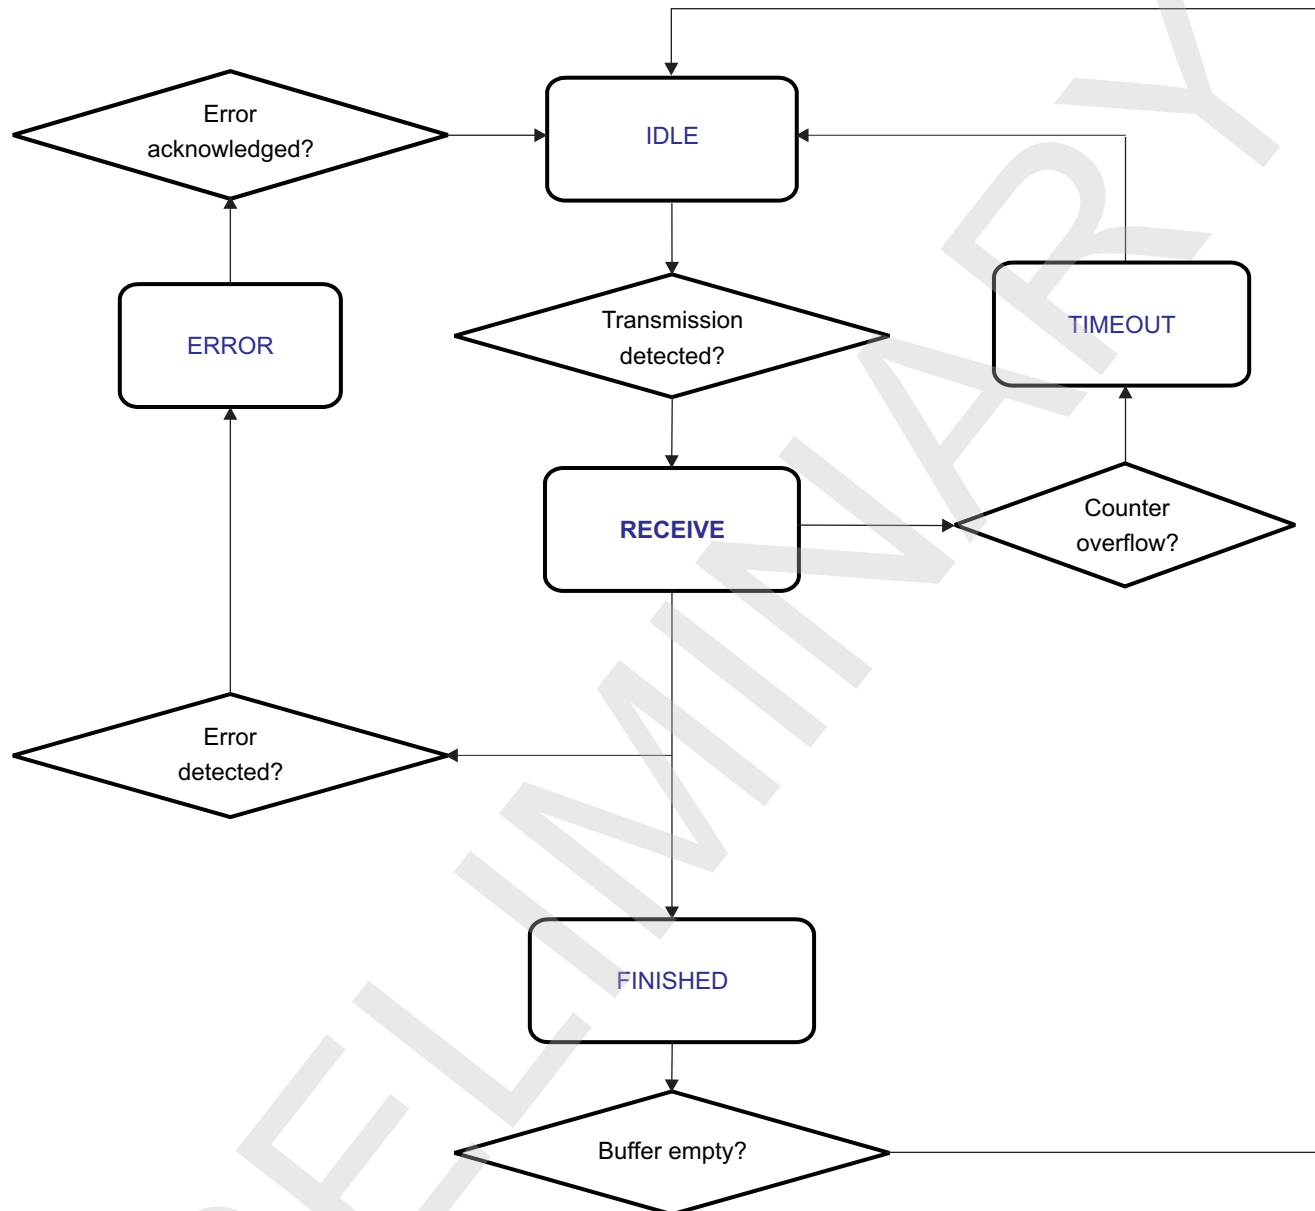

The HSR module is the receiver part of the HSI module. It features 16 channels.

#### 23.10.4.7.1 Receive Data

The value on the DATA line is always the transmitted bit, when sampled by the clock recovered. The double level of buffering allows the data to be safely transferred to the FIFO, while a new frame is stored. Data headers do not belong in FIFO and have to be decoded to load data on the right FIFO (there is one logical FIFO per logical channel).

[Figure 23-224](#) shows the receive state-machine implemented in the HSI module.

Figure 23-224. Receive FSM

hsi-007

### 23.10.4.7.2 Transmission Detection

Reception starts upon two alternate conditions:

- The remote transmitter raises the WAKE line (in this case, it does not actually transmit until the local receiver raises the READY line).
- An activity (in form of transitions) appears on the FLAG/DATA lines, in case the remote transmitter does not implement the WAKE signal. The receiver must then save and store the received data, at least one frame long, before preventing further transmission by setting READY to 0.

### 23.10.4.7.3 Dynamic OPP Changes

If all receive hardware undergoes changes in OPP, operations may have to be stopped, to reprogram a DLL running on different OPP.

A simple software protocol is supported by the [HSR\\_DLL\[4\]](#) COCHGR (change allowed) and [HSR\\_DLL\[0\]](#)

COCHRE (change incoming) bits. When software must change an OPP, it writes 1 on the [HSR\\_DLL\[0\]](#) COCHRE bit. The receiver drops READY to 0 as soon as possible, processes correctly the current frame, and then sets the [HSR\\_DLL\[4\]](#) COCHGR bit. Software could then program the [HSR\\_DLL\[17:8\]](#) INCO bit field or the [HSR\\_DIVISOR\\_Pp\[7:0\]](#) RX\_RATE\_DIV\_VAL bit field, and clear the [HSR\\_DLL\[0\]](#) COCHRE bit when finished. Hardware then clears the [HSR\\_DLL\[4\]](#) COCHGR bit.

### 23.10.4.7.4 Configuration

#### 23.10.4.7.4.1 Mode Register

The [HSR\\_MODE\\_Pp](#) register cannot be changed without stopping the link.

[HSR\\_MODE\\_Pp](#) has the following bit fields:

- [MODE\\_VAL](#) - defines the following operation modes:
  - sleep - specifies whether internal clocks must run and port be operating.
  - stream - receiver does not use start-bits.
  - frame - allows break transmission / reception defined as a longer-than-frame 0 sequence.
- [FLOW\\_VAL](#) - defines the following data flows:
  - Synchronized flow - the receiver drops the READY line every first bit of a received frame, raising it when data is stored.
  - Pipelined flow - the receiver cannot drop the READY line at some times.
  - Real-time flow - the receiver drops the READY at the first received bit and raises it at the last. Data is discarded.

There is one [HST\\_MODE\\_Pp\[3:2\]](#) [FLOW\\_VAL](#) bit field for each active transmit channel and another [HSR\\_MODE\\_Pp\[3:2\]](#) [FLOW\\_VAL](#) bit field for each active receive channel. The local receiver must know its flow mode is (defined by the remote transmitter) to drive the READY line.

#### 23.10.4.7.4.2 Other Registers

- The [HSI\\_Pp\\_SET\\_WAKE\[16\]](#) [HSI\\_3\\_WIRES](#) bit lets hardware know whether WAKE signal is available (when 0x0) or not (when 0x1). Default value is 0x0.
- The [HSR\\_FRAMESIZE\\_Pp](#) register is kept to offer legacy compatibility. It is a read-only register, returning 0x1F.
- The [HSR\\_DIVISOR\\_Pp\[7:0\]](#) [RX\\_RATE\\_DIV\\_VAL](#) bit field sets the clock division ratio for the error detection counters.
- The [HSR\\_CHANNELS\\_Pp\[4:0\]](#) [CHAN\\_NUM\\_VAL](#) bit field sets the number of logical channels. It must be a power of 2. Default value is 0x1. This corresponds to only one logical channel, always the same, and in that case, header is not transmitted. It cannot be changed without stopping the link.

[HSR\\_COUNTERS\\_Pp](#) register sets the value for counters:

- [HSR\\_COUNTERS\\_Pp\[19:0\]](#) FT bit field (frame time-out counter): Maximum number of receive clock cycles to wait for reception of one frame. Afterwards, frame it is considered to have timed out, possibly due to lost synchronization.
- [HSR\\_COUNTERS\\_Pp\[23:20\]](#) TB bit field (tailing bit counter): Maximum number of receive clock cycles to check for possible wrong tailing bit.
- [HSR\\_COUNTERS\\_Pp\[31:24\]](#) FB bit field (frame burst counter): Maximum number of continuous frames to accept to receive in pipelined flow default value for all these values is set to 0, and in that case these checks are disabled.

[HSR\\_MAPPINGf](#) register contains important settings for each FIFO (one register per FIFO):

- [HSR\\_MAPPINGf\[0\]](#) ENABLE bit: FIFO is enabled or not.
- [HSR\\_MAPPINGf\[4:1\]](#) CH\_NUMBER and [HSR\\_MAPPINGf\[7\]](#) PORT\_NUMBER bit fields (channel number and port number): FIFO is assigned to a HSI logical channel on a physical port.
- [HSR\\_MAPPINGf\[13:10\]](#) WORDS: This field holds the number of words to be read (through the L4\_CFG interconnect) upon the interrupt, automatically generated when FIFO pointers are not aligned; therefore, there are data to read. Default value is FIFO enabled and assigned to lower logical channel of each port.

HSR\_DLL register supports a simple software protocol for safe DLL programming:

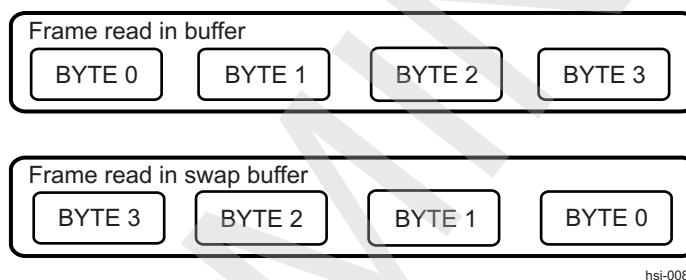

- [HSR\\_DLL\[0\]](#) COCHRE bit: Code Change Request will be set by software when it wants to change DLL code (typically in case of OPP change).
- [HSR\\_DLL\[4\]](#) COCHGR bit: Code Change Grant will be set by hardware when remote side is stopped and no data are incoming.
- [HSR\\_DLL\[17:8\]](#) INCO bit field: Input Code will hold the DLL programming code to be entered into.

#### 23.10.4.7.5 Receive Buffers

For each logical channel, the [HSR\\_BUFFER\\_Pp\\_CHN\\_i\[31:0\]](#) DATA bit field holds one frame. The appropriate bit in the [HSR\\_BUFSTATE\\_Pp](#) register is set to 1 by hardware when the corresponding [HSR\\_BUFFER\\_Pp\\_CHN\\_i](#) register holds one frame. Reading the [HSR\\_BUFFER\\_Pp\\_CHN\\_i\[31:0\]](#) DATA bit field automatically resets the appropriate bit in [HSR\\_BUFSTATE\\_Pp](#). This lets the receiver put another data frame in [HSR\\_BUFFER\\_Pp\\_CHN\\_i](#), setting again [HSR\\_BUFSTATE\\_Pp](#).

Some applications need reversing byte ordering of frames. This is supported by the [HSR\\_SWAPBUFFER\\_Pp\\_CHN\\_i](#) register. By reading this register instead of the corresponding [HSR\\_BUFFER\\_Pp\\_CHN\\_i](#) register on the same channel, byte ordering of the 4 bytes in a frame is reversed.

**Figure 23-225. HSR\_SWAPBUFFER\_Pp\_CHN\_i Register**

Reading MSB of the [HSR\\_SWAPBUFFER\\_Pp\\_CHN\\_i](#) register sets the corresponding bit of [HSR\\_BUFSTATE\\_Pp](#) to empty.

---

**NOTE:** Read access to the register with 0x3 and 0xF byteen removes the receive FIFO-related item. If only 16-bit accesses are used, the upper 2 bytes must be read first (byteen 0xC). Between two consecutive 16-bit FIFO-related accesses there cannot be any other FIFO-related OCP access.

---

#### 23.10.4.7.6 Receive Operations

Logically, the receiver amounts to the receiver shift register, double-buffering and the FSM. Current state of FSM can be observed and even controlled through the [HSR\\_RXSTATE\\_Pp\[2:0\]](#) RXSTATEVAL bit field. For the receive FSM, a functional description is shown in [Figure 23-224](#).

The receiver FSM will be in IDLE state when no transmission is detected, or [HSR\\_MODE\\_Pp\[1:0\]](#) MODE\_VAL bit field = FRAME and no synchronization bit is detected. Otherwise, it stores the first received bit and transitions to RECEIVING state, where it stops until a full frame is received.

Recall that depending on the selected flow control, the READY line may have to go to 0 after the first bit is received.

Upon receiving a full frame, FSM transitions to FINISHED state. Otherwise, FSM transitions to TIMEOUT state as soon as a time-out value (if enabled and programmed in the [HSR\\_COUNTERS\\_Pp\[19:0\]](#) FT bit field is reached. Then it moves to IDLE.

After entering RECEIVED state, FSM will stay there until the received frame has been correctly stored and there is room for another frame. At this point, READY is raised and FSM goes to IDLE. In pipelined flow, flow control by READY is not operating at each byte, and in real time flow it is never operating. In both cases, the FSM transitions right away to IDLE, to receive more data. Illegal transitions or flags rose by error counters (see [Section 23.10.4.11](#), *Error Reporting*), move FSM to ERROR state, and then to HALT, to wait until error is acknowledged by software, warned by an interrupt. Except for pipelined control flow, the READY output is always 1 in IDLE state and 0 anywhere else. In pipelined mode, the READY signal stays to 1, and is cleared by a condition on buffer full. FSM state can be controlled by software by writing in the [HSR\\_RXSTATE\\_Pp\[2:0\]](#) RXSTATEVAL bit field. This can be useful to recover from error condition.

### **23.10.4.7.7 Receive Exceptions**

#### **23.10.4.7.7.1 Break**

Remote transmitter can force synchronization by a long enough string of 0 (equal to the number of header + data bits in the frame + 1). In FRAME mode, this sets the [HSR\\_BREAK\\_Pp\[0\]](#) BREAK\_VAL bit to 1, which in turn sends an interrupt.

#### **23.10.4.7.7.2 Overrun**

Overrun condition is possible during real-time flow, if received data occur when FSM is in FINISHED state. Whenever this happens, the [HSR\\_OVERRUN\\_Pp\[15:0\]](#) OVERRUN\_VAL bit field is set for the corresponding logical channel, which in turn generates an interrupt.

Overrun exception is a legacy condition absolutely needed in previous SSI hardware, where reception without READY signal had to be supported. In HSI we always have READY signal. But it cannot be used during real-time flow and the last 8 bits of a frame during pipelined flow. During real-time data flow, overrun could occur at any time. Main goal of using real-time flow is flushing FIFOs after an error, and in that case overrun interrupt does not seem worth to be raised. Data need not be discarded. The real-time data are discard if receiver cannot follow the transmission rate, otherwise, the real-time data is kept in FIFO.

#### **23.10.4.7.7.3 Errors**

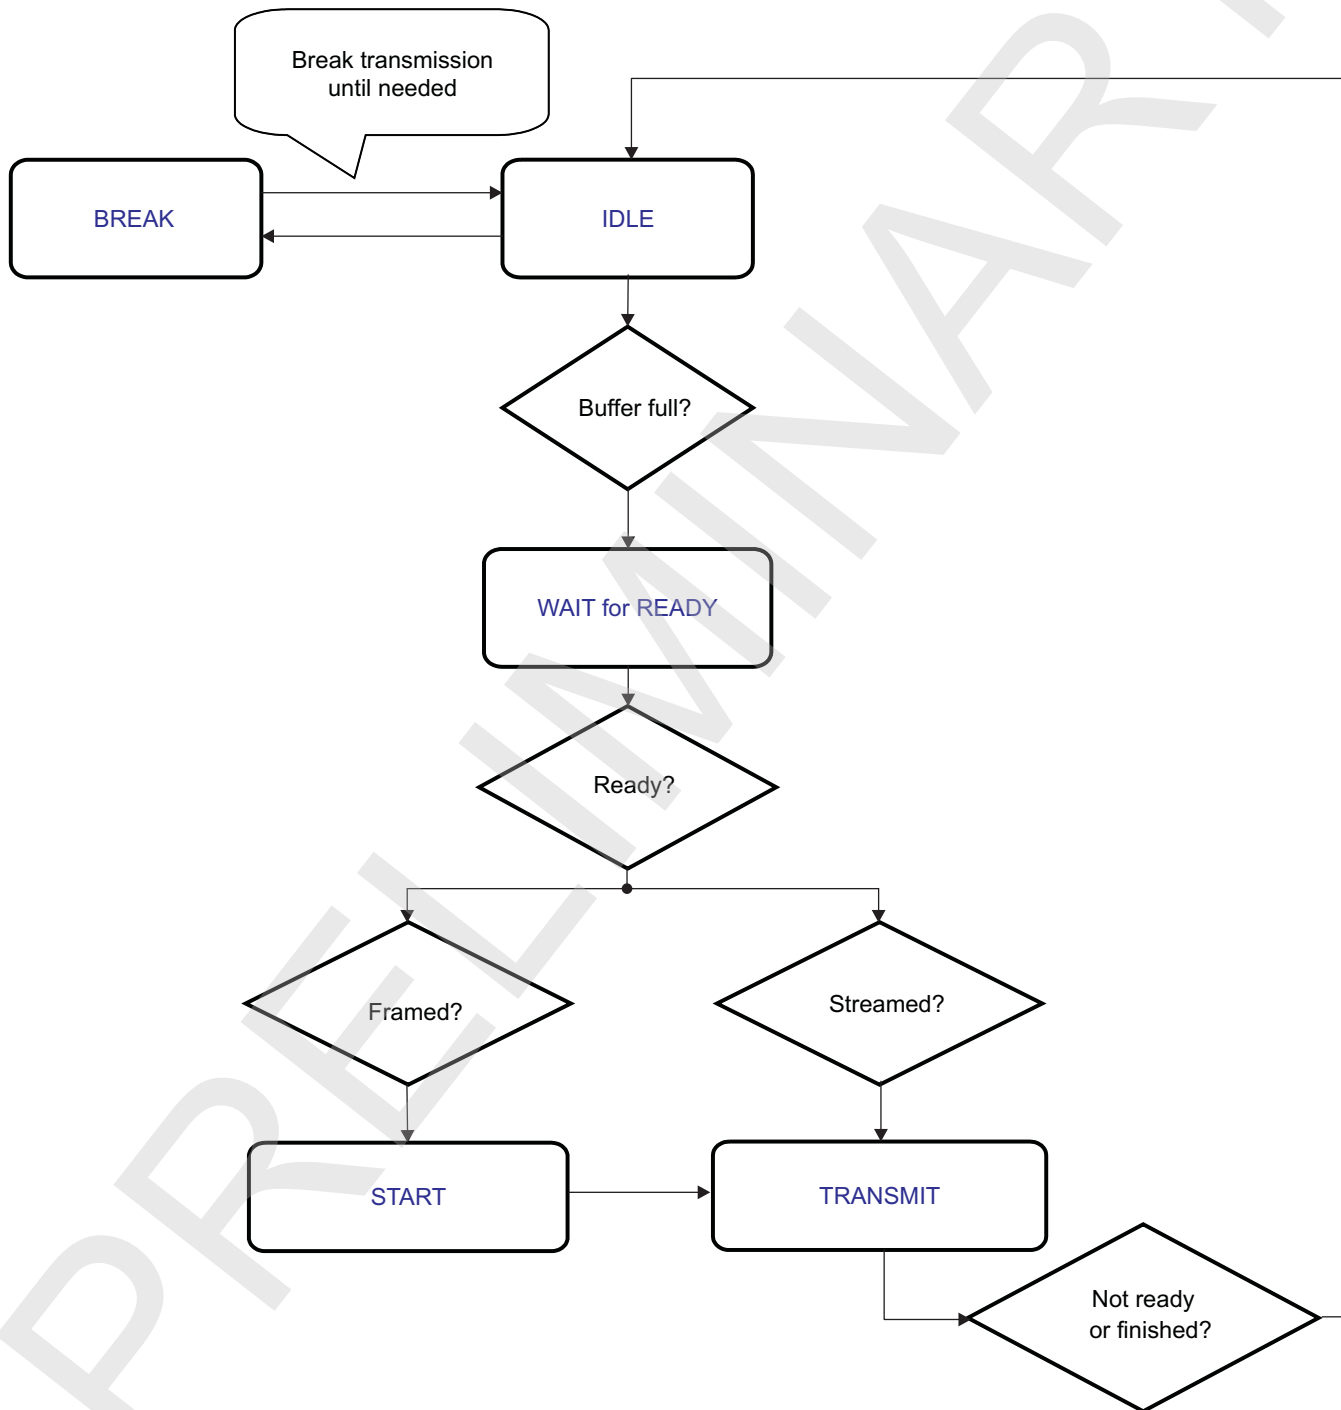

Several sources of errors are possible. In any of them, receiver FSM stays in HALT state until the error interrupt is acknowledged by software; that writes the [HSR\\_ERROR\\_Pp](#) and [HSR\\_ERRORACK\\_Pp](#) registers. Sources of errors include receive FRAME TIMEOUT, other receive errors flagged by error counters, and any other abnormal condition as explained in [Section 23.10.4.11](#), *Error Reporting*.

### 23.10.4.8 HST Block

The HST block is the transmitter part of the HSI module. It features 16 channels.

Figure 23-226 shows the receive state-machine implemented in the HSI module.

**Figure 23-226. Transmit FSM**

hsi-0009

#### 23.10.4.8.1 Configuration

Configuration of the component is expressed in terms of operation mode, number of logical channels, bit rate divisor, and arbitration mode.

### 23.10.4.8.1.1 Mode Register

The `HST_MODE_Pp` register cannot be changed without stopping the link.

There is one `HST_MODE_Pp[3:2]` `FLOW_VAL` bit field for each active transmit channel and another `HSR_MODE_Pp[3:2]` `FLOW_VAL` bit field for each active receive channel. The local transmitter (communicating with the remote receiver) uses the `HST_MODE_Pp[3:2]` `FLOW_VAL` bit field for interpretation of the received `READY` line, for example to signal errors.

The `HST_MODE_Pp` register has the following bit fields:

- `WAKE_CTRL` - selects between software (when 0x0) or automatic (when 0x1) control for the `WAKE` line. Default is software control.
- `MODE_VAL` - defines the following operation modes:
  - sleep - specifies whether internal clocks must run and port be operating.
  - stream - receiver does not use start-bits.
  - frame - allows break transmission / reception defined as a longer-than-frame 0 sequence.
- `FLOW_VAL` - defines the following data flows:
  - Synchronized flow - the `READY` signal from receiver drops after every first frame bit, rising when data are stored, and transmission of a new frame is possible.
  - Pipelined flow - the receiver cannot drop the `READY` line at some times.
  - Real-time flow - the receiver drops the `READY` line at the first received bit and raises it at the last one.

### 23.10.4.8.1.2 Other Registers

- The `HST_FRAME_SIZE_Pp` register is kept to offer legacy compatibility. It is a read-only register, returning 0x1F.
- The `HST_DIVISOR_Pp[7:0]` `RX_RATE_DIV_VAL` bit field sets the transmission bit rate, with 1 transmitted bit per clock cycle. Bit rate can be changed by software at any time.
- The `HST_CHANNELS_Pp[4:0]` `CHAN_NUM_VAL` bit field sets the number of logical channels. It must be a power of 2. Default value is 0x1. This corresponds to only one logical channel, always the same, and in that case, header is not transmitted. It cannot be changed without stopping the link.
- `HST_MAPPINGf` contains important settings for each FIFO (one register per FIFO):
  - `HST_MAPPINGf[0]` `ENABLE` bit: FIFO is enabled or not.
  - `HST_MAPPINGf[4:1]` `CH_NUMBER` and `HSR_MAPPINGf[7]` `PORT_NUMBER` bit fields (channel number and port number): FIFO is assigned to a HSI logical channel on a physical port.
  - `HST_MAPPINGf[13:10]` `THRESHOLD` bit field is the number of empty TX FIFO locations that will activate interrupt automatically.
- The `HST_ARBMODE_Pp[0]` `ARB_VAL` bit allows to choose arbitration policy for time allocation to logical channels, when several channels have to transmit. Round-robin algorithm implements a circular scan: the same channel cannot transmit twice if another channel is ready to transmit. Scan proceeds in the same, unspecified direction (design choice). Fixed priority algorithm grants maximum priority to logical channel 0, minimum priority to channel 15. The right to transmit is assigned to the higher priority channel ready to transmit, independently of previous transmissions.

The choice between algorithms must consider that round-robin sets a maximum wait time for each channel, but it may require a long time to transmit long sequences of frames, on any channel. On the other hand, fixed priority allows to limiting transmission time for high priority channels, while low priority channel might be waiting for a long time.

It is important to understand that this register sets the allocation of one port resource (transmission lines) between 2 up to 16 vying transmit FIFO. Allocation of the 16 transmit FIFO to 32 logical channels is done by the `HST_MAPPINGf` register. For this second kind of allocation, no arbitration makes sense, because software is in charge to ensure against more than 16 logical channels transmitting at the same time.

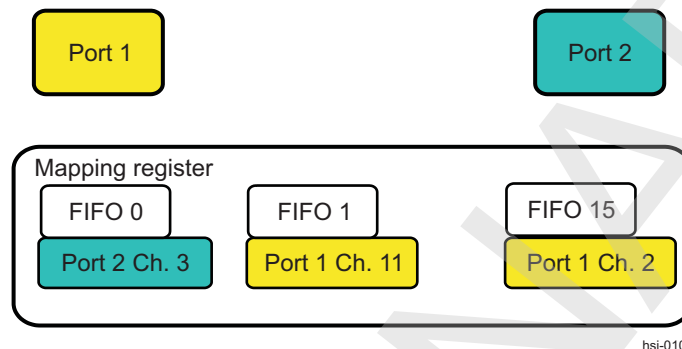

### 23.10.4.8.2 Mapping

Figure 23-227 shows an example of programming the `HST_MAPPINGf` register. No limitation is set on the choice of channel/FIFO/port association.

Each port has its [HST\\_ARBMODE\\_Pp](#) register, so that it is also possible to program alternate algorithms on ports.

While the [HST\\_MAPPINGf](#) register only cares about FIFO, the [HST\\_ARBMODE\\_Pp](#) register is associated to a port and each port has got its own one, which only selects a winner between ready-to-transmit channels of this port. For example, suppose that in [Figure 23-227](#), only the three represented channels need to transmit; then a "yellow" (port 1) arbiter will choose between channel 11 and channel 2, while the "cyan" (port 2) arbiter will have no decision to take and let channel 3 transmit.

**Figure 23-227. MAPPING Register**

#### 23.10.4.8.3 Transmission Buffer

Transmission buffer holds a frame to be transmitted for each channel. The [HST\\_BUFSTATE\\_Pp\[7:0\]](#) [BUFSTATE\\_VAL](#) bit field tells whether [HST\\_BUFFER\\_Pp\\_CHN\\_i\[31:0\]](#) [DATA](#) holds significant data, and it is not be cleared until transmit FSM is in IDLE and arbitration tells the channel is the next in line to transmit. The [HST\\_BUFSTATE\\_Pp](#) register is automatically written by hardware.

---

**NOTE:** Write access to the register with 0x3 and 0xF byteen loads its value into the transmit FIFO. If only 16-bit accesses are used, the upper 2 bytes must be written first (byteen 0xC). Between two consecutive 16-bit FIFO-related accesses there cannot be any other FIFO-related OCP access.

---

Some applications need reversing byte ordering of frames. This is supported by the [HST\\_SWAPBUFFER\\_Pp\\_CHN\\_i](#) register. By reading this register instead of the corresponding [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) register on the same channel, byte ordering of the 4 bytes in a frame is reversed (see [Section 23.10.4.7.5, Receive Buffers](#)).

#### 23.10.4.8.4 Break Pattern Transmission

Break pattern transmission is an alternate option to normal transmission mode, used when trying to recover lost synchronization. It is started by software, by writing the [HST\\_BREAK\\_Pp\[0\]](#) [BREAK\\_VAL](#) bit. As soon as transmit FSM is in IDLE state, (ready to accept another frame for transmission), a nonzero value on the [HST\\_BREAK\\_Pp\[0\]](#) [BREAK\\_VAL](#) bit starts the BREAK sequence, and automatically clears the [HST\\_BREAK\\_Pp\[0\]](#) [BREAK\\_VAL](#) bit. A sequence of 0, longer than a frame is transmitted.

#### 23.10.4.8.5 Transmission Operations

Transmitter adds up to the transmit shift register, loaded from the transmission buffer, and the transmit FSM current state of the FSM can be observed and even controlled through the [HST\\_TXSTATE\\_Pp\[2:0\]](#) [TXSTATEVAL](#) bit field. A functional description of the transmit FSM is shown in [Figure 23-226](#).

After reset, transmitter is in IDLE state. It starts transmission when there is data in one of the transmission [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) registers, depending on the value of [HST\\_BUFSTATE\\_Pp\[7:0\]](#) [BUFSTATE\\_VAL](#) bit field, or when BREAK value is not 0.

When transmitting a data frame (not a BREAK sequence), the frame to be transmitted is clocked from the [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) register to the transmission shift register, and the FSM enters WAIT state, until it gets READY = 1. At this point, it starts driving DATA and FLAG line, either with a preliminary start bit at 1, if in STREAM mode, or with the frame, amounting to header and payload data.

In case of synchronized data flow, TRANSMIT state is left after one frame is transmitted, because READY always drops after the first transmitted bit. Transmit FSM transitions through IDLE and WAIT before starting to transmit again, when READY rises.

In case of pipelined data flow, transmit FSM stays in TRANSMIT state as long as READY = 1, and transmission goes on, always clocking data from the appropriate [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) register, as selected by arbitration. Transmission is stopped by the condition READY = 0, forcing FSM to go into IDLE state. READY is not supposed to switch during the last 8 nominal bit times.

### 23.10.4.8.6 Transmission Exceptions

There are no transmission errors. Reception of READY = 0 in the last 8 bits of frames is not flagged. DATA ACCEPTED interrupt is used to tell software that the [HST\\_BUFFER\\_Pp\\_CHN\\_i\[31:0\]](#) DATA bit field is empty and to ask for more data.

### 23.10.4.9 HSI Wake Generator

The WAKE line is used to create a wake-up event for the external module interfacing with HSI before a data transfer through the HSI serial interface.

The 16 bits (1per HSI channel) of the [HSI\\_Pp\\_WAKE\[15:0\]](#) WAKE\_CHI bit field are ORed together to drive the WAKE line, as shown in [Figure 23-228](#).

**Figure 23-228. HSI\_Pp\_WAKE Control in Case of Managed Wake**

hsi-011

The wake generator can be managed by software operations or automatically by hardware. If the wake generator is not managed, the WAKE signal will be driven to 0 and the remote transmitter is in charge of awaking itself on activity detection on DATA/FLAG lines.

### 23.10.4.9.1 Software Management of HSI Wake Generator

Software can get the responsibility to use/manage those bits to create and release wake-up events consistently with HSI use.

Because the [HSI\\_Pp\\_WAKE\[15:0\] WAKE\\_CHI](#) bit field can be managed by different threads/processors, this mechanism allows independent bit management by each thread. Without locking the [HSI\\_Pp\\_WAKE](#) register (like a read-modify-write would do), it avoids one thread to overwrite the register change made by another thread. Each bit of the [HSI\\_Pp\\_SET\\_WAKE\[15:0\] HSI\\_SET\\_WAKE\\_CHI](#) bit field is owned by one thread at a time.

- The thread can set this bit by writing 1 into the corresponding bit of the [HSI\\_Pp\\_SET\\_WAKE\[15:0\] HSI\\_SET\\_WAKE\\_CHI](#) bit field. This sets only this bit, thus leaving the other bits unchanged (no need of a read-modify-write).
- The thread can clear this bit by writing 1 into the corresponding bit of the [HSI\\_Pp\\_CLEAR\\_WAKE\[16:0\] HSI\\_HSI\\_CLEAR\\_WAKE\\_CHI](#) bit field. This clears only this bit, thus leaving the other bits unchanged (no need of a read-modify-write).

### 23.10.4.9.2 Automatic Management of HSI Wake Generator

The wake generator is automatically managed when there is a transmission to be performed. When data are waiting for transmission in a FIFO TX, the hardware sets the corresponding bit of the [HSI\\_Pp\\_WAKE\[15:0\] WAKE\\_CHI](#) bit field, and this raises WAKE signal on port *p*. Then WAKE deassertion is done by the first occurrence of one event between a fixed time-out from end of last transfer, a transition to idle in idle-req protocol, a software clear of register.

### 23.10.4.10 FIFO Subsystem

The FIFO subsystem allows temporary buffering while Receive Data is transferred from Receiver through DMA or the L4 interconnect to main memory, and to store Transmit Data read in main memory through DMA, (or written by L4) before transmitting it. FIFO depth is 8 x 32-bit words for each channel, yielding a total size of 1KB with 16 bidirectional channels.

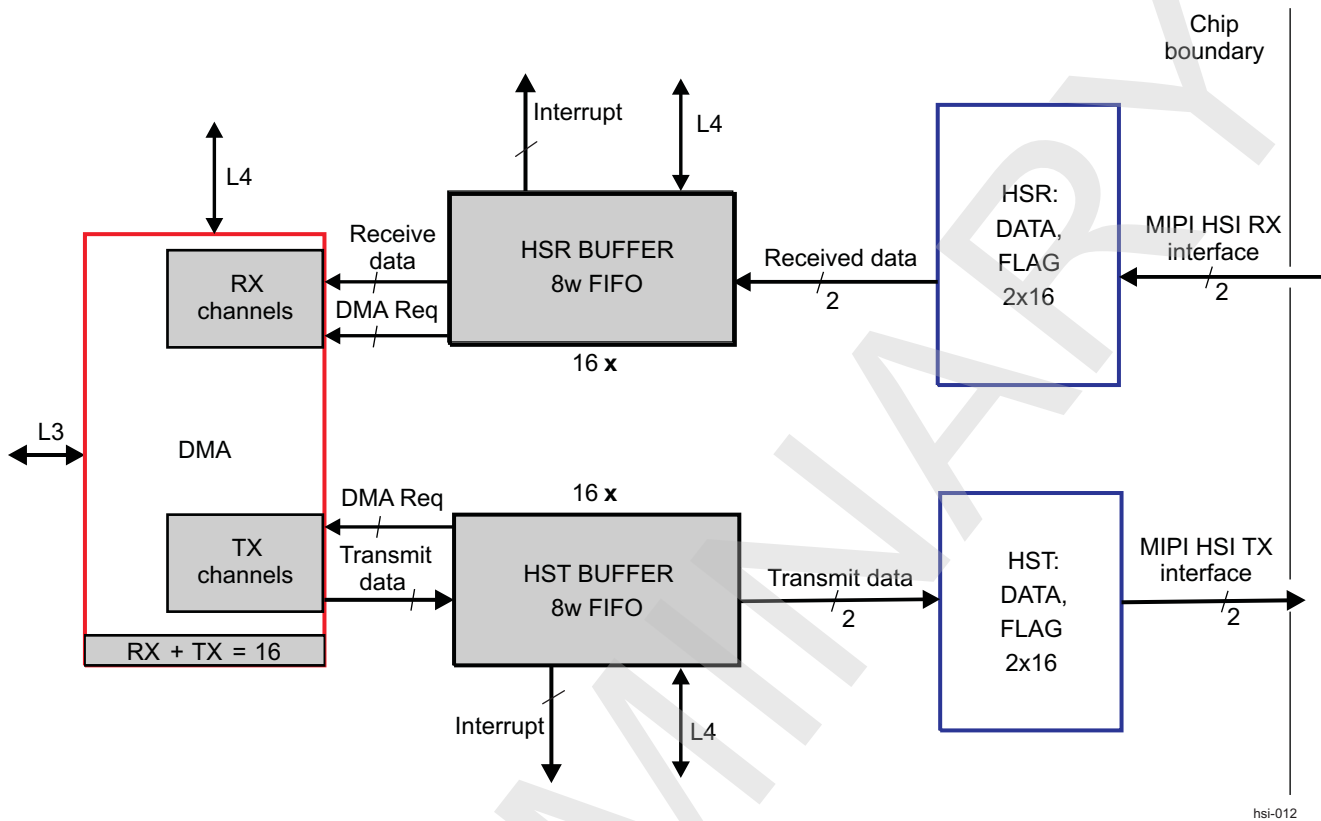

RX FIFOs are clocked by interconnect clock, TX FIFOs are clocked by undivided functional clock.

#### 23.10.4.10.1 FIFO Subsystem Architecture

[Figure 23-229](#) shows the overall FIFO architecture.

Figure 23-229. Overall FIFO Architecture

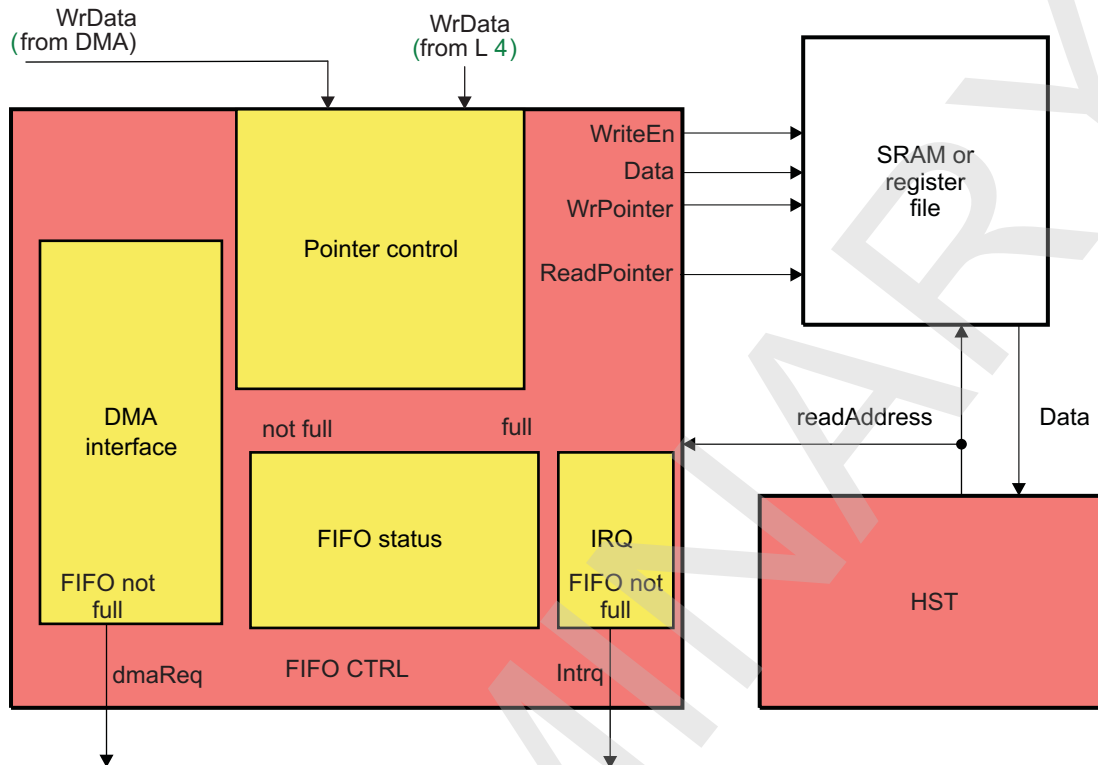

There are 16 total DMA channels available. They can be used for RX or TX in any combination; direction is programmable.

There are 16 RX FIFOs and 16 TX FIFOs. Not all FIFO can be served by DMA, but all RX FIFO (or else TX FIFO) could be served by DMA, if needed. The other FIFOs, if used, must be read/written through the L4\_CFG interconnect.

Both HSI ports provide up to 16 x 2 logical channels. This means that only one half of the HSI logical channels can be accommodated on the existing FIFOs. The others must not be used, and their use has to flag an error. The 16 [HST\\_MAPPINGf](#) or [HSR\\_MAPPINGf](#) registers specify which HSI logical channel number is allowed to be received on RX FIFOs and/or fed for transmission by TX FIFOs. There is one mapping register for transmission and one for reception. Any attempt to transmit or process received data on HSI logical channels not previously mapped on mapping registers results in an error. In other words, some header values (bits 35 down to 32) are not allowed at any given time, and generate an error when received. Software must ensure that the remote side sends payload on the allowed logical channels, specified by header values.

### 23.10.4.10.2 Transmit FIFO Architecture

Figure 23-230 shows the transmission FIFO architecture.

**Figure 23-230. Transmission FIFO Architecture**

hsi-013

FIFO controller flags the condition of "room available in FIFO", or "FIFO not full", at any time when FIFO can host new data for transmission. This condition raises an interrupt request and a DMA request, if enabled. A programmable threshold in the corresponding `HST_MAPPING[13:10] THRESHOLD` bit field reduces the number of requests, ( they might be sent only whether four words can be written in FIFO). Default value for threshold is 0x0 (i.e., request rises as soon as one word can be written in FIFO). See [Table 23-792](#)

**Table 23-792. Threshold for Transmit FIFO Interrupt/DMA Request**

<code>HST_MAPPING[13:10] THRESHOLD</code>	Number of Words in FIFO	Request
0 (legacy default)	Less than 8	Yes
1	Less than 1	Yes
2	Less than 2	Yes
3	Less than 3	Yes
4	Less than 4	Yes
5	Less than 5	Yes
6	Less than 6	Yes
7	Less than 7	Yes
8	Less than 8	Yes
9 to 15	any	No

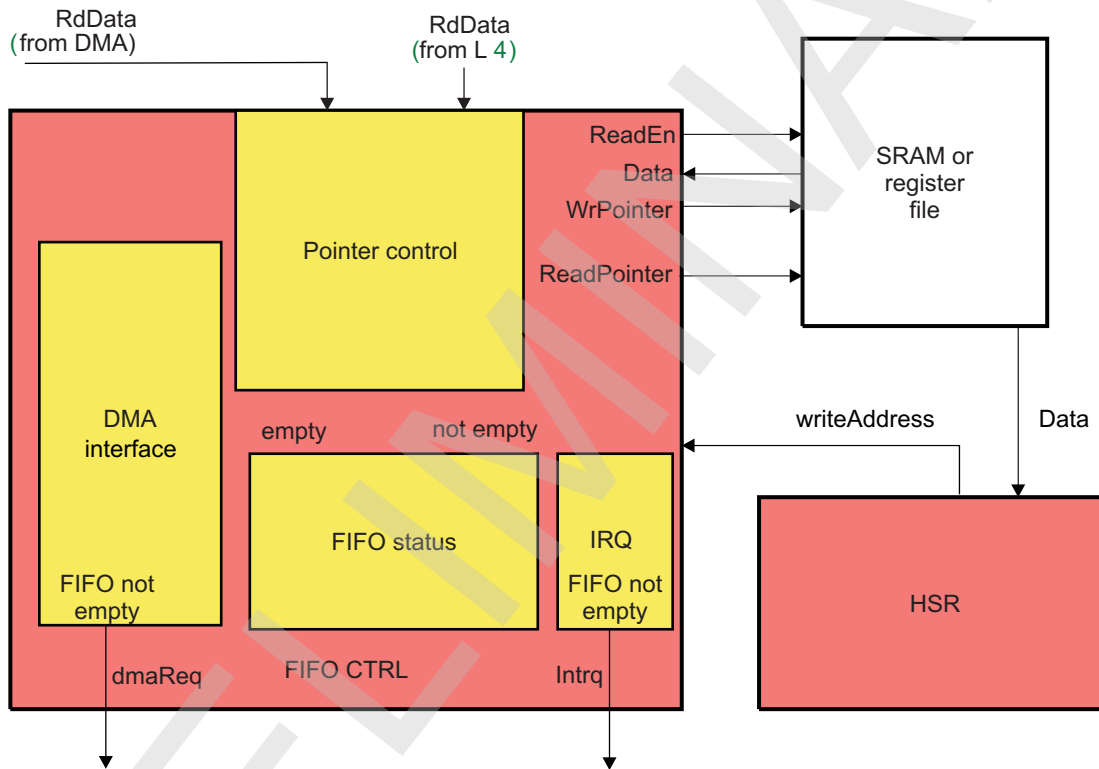

FIFO can be written by DMA and the L4 interconnect configuration port, but the L4 interconnect has fixed priority at any time. Software is in charge of controlling correct access. No hardware mechanism is provided to analyze and block concurrent operation, nor is any hardware control provided on reprogramming DMA registers during a transfer in which they are involved.

The address of FIFO is the corresponding [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) register address. The FIFO controller is in charge of generating actual RAM addresses, namely managing write pointer when DMA or the L4 interconnect access the [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) address, and managing read pointer when HST needs a data to transmit.

**23.10.4.10.3 Receive FIFO Architecture**

Figure 23-231 shows the reception FIFO architecture.

**Figure 23-231. Reception FIFO Architecture**

FIFO controller flags the condition of "unread data in FIFO", or "FIFO not empty", at any time when a FIFO hosts new data, received and not read. This condition can be simply the misalignment of Read Pointer and Write Pointer. The condition raises an interrupt request and a DMA request, if enabled. The [HSR\\_MAPPING\[13:10\] WORDS](#) bit field tells software how many words must be read.

Unlike transmission, it is not possible here to filter requests through a threshold on the number of received words. If such a threshold is bigger than one, and a last single word is received after last read, software would have no clue that more data awaits to be read.

The address of FIFO is the corresponding [HSR\\_BUFFER\\_Pp\\_CHN\\_i](#) register address. The FIFO controller is in charge of generating actual RAM addresses; namely managing write pointer when HSR has received data, and managing read pointer when DMA or the L4 interconnect access the [HSR\\_BUFFER\\_Pp\\_CHN\\_i](#).

#### 23.10.4.10.4 FIFO Addressing

From a software point of view, a FIFO is seen at a single address the corresponding [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) or [HSR\\_BUFFER\\_Pp\\_CHN\\_i](#) register address. The [HST\\_SWAPBUFFER\\_Pp\\_CHN\\_i](#) or [HSR\\_SWAPBUFFER\\_Pp\\_CHN\\_i](#) register address is also provided, to invert data endianness with byte granularity. FIFO overflow in RX is extremely unlikely, because of the huge difference in HSI and L3 interconnect bit rate. However, if this occurs, the hardware prevents any loss of data by deasserting (putting to 0) the READY signal to the remote transmitter. FIFO overflow in TX is not flagged and must be avoided by software drivers.

#### 23.10.4.11 Error Reporting

##### 23.10.4.11.1 Detection of Errors

Error detection on the module is limited to the physical layer. No data corruption is checked, and no error is flagged as long as receiver and transmitter agree on frame boundaries. As both clocking and data is recovered from alternate edges on DATA and FLAG signals, three kinds of error can appear:

- Simultaneous edges
- Missing edges
- Additional edges

##### 23.10.4.11.1.1 Simultaneous Edges

Transmitter is not supposed to produce simultaneous edges on DATA and FLAG signals, but they can show up if transmission rate is far higher than what the receiver can handle. Given to the sampling protocol, this event may introduce errors in sampled data. Detecting this error is not easy, as the recovered clock will be affected as well, and in some configurations no other clock is available. One bit is available in the [HSR\\_ERROR\\_Pp](#) register, to report any hardware abnormal condition in data reception.

##### 23.10.4.11.1.2 Missing Edges

Missing edges result in missing clock cycles, thus causing the receiver to get less data than expected on a given frame.

In synchronized flow, when the transmit side has completed transmission, the receiver side is still waiting for more data, and does not raise READY, thus stopping transmitter from going on with more frames. A frame time-out counter (see [Section 23.10.4.11.2.1, Frame Time-Out Counter](#)) is used to escape this deadlock condition.

In pipelined flow, when the transmit side has completed transmission and has more data to transmit, the receiver accepts and processes this data as if they were part of the previous frame. Frame synchronization is then lost. It may randomly resume when in frame mode, as zeroes at the end of a frame are automatically discarded. But even in this case, a number of frames might be lost or corrupted. When in stream mode, no self-recovery is ever possible, and synchronization is lost forever. A frame burst counter (see [Section 23.10.4.11.2.3, Frame Burst Counter](#)) is used to limit the number of these potentially corrupted frames, simply by limiting the number of frames a transmitter can send back-to-back in a pipelined mode. A tailing bit counter (see [Section 23.10.4.11.2.2, Frame Tailing Bit Counter](#)) is used to check that the receiver and transmitter agree on being at the end of frame.

##### 23.10.4.11.1.3 Additional Edges

Additional edges result in additional clock cycles, thus causing the receiver to get more data than expected on a given frame.

In synchronized flow, when the receive side thinks the frame is over, the transmitter keeps sending data until the end of frame is reached. In frame mode, if these additional bits are all 0s, they are discarded by the receiver, then transmission stops, and the receiver raises READY when it is available to receive a new frame. The transmit side starts a new frame and synchronization is recovered. But if the additional bits are 1 (at least one), this can misguide the receiver that a new frame has already started and READY stays at

0. The transmit side stops, waiting for  $READY=1$ , never occurring condition, as the receiver has lost synchronization. In this case, the link is stuck. This is also the case in stream mode, when the receiver wrongly thinks that a new frame is started, so it is not available to receive a full new frame, and it does not set  $READY=1$ . A frame time-out counter (see [Section 23.10.4.11.2.1, Frame Time-out Counter](#)) is used to escape this deadlock condition.

### 23.10.4.11.2 Error Counters

Clocks for these three counters are provided through a division of functional clock. These counters can be set to a value, and can be stopped when some events occur. Events flag errors and set a corresponding bit in the [HSR\\_ERROR\\_Pp](#) register.

#### 23.10.4.11.2.1 Frame Time-out Counter

This counter is clocked by the functional clock, divided by the factor specified in the [HSR\\_DIVISOR\\_Pp\[7:0\] RX\\_RATE\\_DIV\\_VAL](#) bit field, to provide a clock at receive bit rate. Receive bit rate is always communicated by remote transmitter through protocol layer. This counter starts when the first bit of the frame is found, and stopped when 36 (or 37 depending on the mode) bits are correctly received by receiver. If the counter overflows, an error is generated (the [HSR\\_ERROR\\_Pp\[1\] FTE](#) bit is set to 0). In OPP reduction of functional clock only (receive side kept in fixed voltage domain), software can decide to reduce either the division factor for the clock, or the count, to use a clock consistent with receive rate, or a reduced count of a slower clock. This is transparent for hardware. This counter is not started when receive rate is outside the full error detection rate range.

#### 23.10.4.11.2.2 Frame Tailing Bit Counter

This counter can be clocked by the same clock as frame timeout counter, which has the receiver bit rate frequency. It starts after reception of the last bit of a frame, and  $READY = 0$ ; in pipelined flow, this counter is only started after the end of the last frame received. No event stops the counter, except its own overflow. It counts up to 8. An error is logged (the [HSR\\_ERROR\\_Pp\[4\] TBE](#) bit is set to 0) if a 1 bit is received in frame mode before counter overflow, or any bit is received in stream mode before counter overflow. In OPP reduction of functional clock only (receive side kept in fixed voltage domain), software can decide to reduce either the division factor for the clock, or the count, to use a clock consistent with receive rate, or a reduced count of a slower clock. This is transparent for hardware. This counter is not started when receive rate is outside the full error detection rate range.

#### 23.10.4.11.2.3 Frame Burst Counter

Differently from previous counters, this counter is clocked by a frame synchronization signal obtained by received data directly. Its goal is to reduce the number of contiguous frames sent in pipelined flow. As seen in [Section 23.10.4.11.1, Detection of Errors](#), in some cases after missing/additional clock cycles, synchronization is lost and these pipelined frames can be corrupted. Software sets the count value, which can be as high as 256 (no higher values are supported by hardware). If  $READY$  is dropped to 0, for reasons other than counter expiration, the counter is stopped and restarted as soon as transmission resumes. At the end of the count,  $READY$  drops to 0. The tailing bit counter is started, and if it overflows without error detection, and receiver has enough room for another frame,  $READY$  is reset to 1. No error and no interrupt are generated on this counter.

### 23.10.4.11.3 Error Registers

One error register per port is provided to check the error source that issued an interrupt, with more details than the error bit in the interrupt status register.

The [HSR\\_ERROR\\_Pp\[0\] SIG](#): Signal error bits are kept for legacy reason, and they can be used for any abnormal situation the hardware wants to flag.

The [HSR\\_ERROR\\_Pp\[1\] FTE](#): Frame time-out error bits flag the situation when not even a frame has been received in the time corresponding to two or more frames, depending on FTE counter software setting.

The [HSR\\_ERROR\\_Pp\[4\] FBE](#): Tailing bit error bits flag the situation when at least one spurious bit is received after the end of a frame, in the time corresponding to two or more bit time.

The [HSR\\_ERROR\\_Pp\[7\]](#) RME: Receive mapping error bits flag the situation when data are received on a channel that is not mapped to any enabled FIFO.

The [HSR\\_ERROR\\_Pp\[11\]](#) TME: Transmit mapping error bits flag the situation when DMA tries to access a FIFO that is not mapped to any logical channel, or not enabled.

These two registers have each a companion [HSR\\_ERRORACK\\_Pp](#) register, where software must set the corresponding error bit to 1 to clear it.

PRELIMINARY

## 23.10.5 HSI Programming Guide

### 23.10.5.1 HSI Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the HSI module.

#### 23.10.5.1.1 Global Initialization

##### 23.10.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the HSI module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the HSI.

See [Section 23.10.3, HSI Integration](#), for further information.

**Table 23-793. Global Initialization of Surrounding Modules for HSI**

Surrounding Modules	Comments
PRCM	HSI functional and interface clocks must be enabled. For more information, see <a href="#">Chapter 3</a>
Control Module	Module specific pad muxing must be set in the control module. For more information, see <a href="#">Chapter 18</a> .
(Optional)Interrupt Controller	Cortex-A9 MPU, or Cortex-M3 MPU, or DSP interrupt controller must be configured to enable the interrupt request generation to the Cortex-A9 MPU, or Cortex-M3 MPU, or DSP subsystem. For information about enabling interrupts, see <a href="#">Chapter 5</a> .
(Optional)Interconnect	For information about the L4 interconnect configuration, see <a href="#">Chapter 13, Interconnects</a> For information about L3 interconnect configuration, see <a href="#">Chapter 13, Interconnects</a>

##### 23.10.5.1.1.2 HSI Global Initialization

###### 23.10.5.1.1.2.1 Main Sequence - HSI Global Initialization

This procedure initializes the HSI module after a power-on or software reset.

**Table 23-794. HSI Global Initialization**

Step	Register / Bit Field / Programming Model	Value
Perform a HSI software reset.	<a href="#">HSI_SYSCONFIG</a> [1] SOFTRESET	0x1
<b>WAIT UNTIL</b> HSI reset is complete.	<a href="#">HSI_SYSSTATUS</a> [0] RESETDONE	= 0x1

### 23.10.5.1.2.1.5 Main Sequence -HSI DMA Mode

#### 23.10.5.1.2.1.5.1 Sub-sequence - DMA Configuration

**Table 23-804. HSI DMA Configuration**

Step	Register / Bit Field / Programming Model	Value
Perform a DMA software reset.	DMA_GRST[0] SWRESET	0x1
<b>WAIT UNTIL</b> DMA reset is complete.	DMA_GRST[0] SWRESET	= 0x0
Set autoidle mode configuration for DMA.	DMA_GCR[3] AUTOGATING	0x1
Configure HSI DMI Receiver.	Refer to <a href="#">Table 23-805</a>	
Configure HSI DMI Transmit.	Refer to <a href="#">Table 23-806</a>	
Enable DMA Interrupts.	Refer to <a href="#">Section 23.10.5.1.2.1.5.4</a>	
Enable DMA channel to start DMA transfer.	DMA_CCR_CSDP_[23] ENABLE	0x1
<b>WHEN DMA INTERRUPT OCCURS</b>	Refer to <a href="#">Table 23-799</a>	

#### 23.10.5.1.2.1.5.2 Sub-sequence - DMA Receive Mode

**Table 23-805. Configure DMA Receive Mode**

Step	Register / Bit Field / Programming Model	Value
Set the transfer source to peripheral port.	DMA_CCR_CSDP_[5:2] SRC	0x9
(Optional) Set the source burst enable.	DMA_CCR_CSDP_[8:7] SRC_BURST_EN	0x1
Set the transfer destination to memory port.	DMA_CCR_CSDP_[12:9] DST	0x8
(Optional) Set the destination burst enable.	DMA_CCR_CSDP_[15:14] DST_BURST_EN	0x1
Set the source addressing mode to constant address.	DMA_CCR_CSDP_[29:28] SRC_ADD_MODE	0x0
Set the destination addressing mode to post-incremented address.	DMA_CCR_CSDP_[31:30] DST_ADD_MODE	0x1
Set the source start address .	DMA_CSSA_i[31:0] ADDR	0x-
Set the destination start address.	DMA_CDSA_i[31:0] ADDR	0x-
Set the number of elements in a block.	DMA_CEN_i[15:0] SIZE	0x-

#### 23.10.5.1.2.1.5.3 Sub-sequence - DMA Transmit Mode

**Table 23-806. Configure DMA Transmit Mode**

Step	Register / Bit Field / Programming Model	Value
Set the transfer source to memory port.	DMA_CCR_CSDP_[5:2] SRC	0x8
(Optional) Set the source burst enable.	DMA_CCR_CSDP_[8:7] SRC_BURST_EN	0x1
Set the transfer destination to peripheral port.	DMA_CCR_CSDP_[12:9] DST	0x9
(Optional) Set the destination burst enable to single access.	DMA_CCR_CSDP_[15:14] DST_BURST_EN	0x1
Set the source addressing mode to post-incremented address.	DMA_CCR_CSDP_[29:28] SRC_ADD_MODE	0x1
Set the destination addressing mode to constant address.	DMA_CCR_CSDP_[31:30] DST_ADD_MODE	0x0

**Table 23-806. Configure DMA Transmit Mode (continued)**

Step	Register / Bit Field / Programming Model	Value
Set the source start address.	DMA_CSSA_i[31:0] ADDR	0x-
Set the destination start address.	DMA_CDSA_i[31:0] ADDR	0x-
Set the number of elements in a block.	DMA_CEN_i[15:0] SIZE	0x-

#### 23.10.5.1.2.1.5.4 Sub-sequence - Enable DMA Interrupts

**Table 23-807. Enable DMA Interrupts**

Step	Register / Bit Field / Programming Model	Value
Enable the DMA channels that shall generate an interrupt to a processor (MPU and/or DSP).	HSI_DMA_M_IRQENABLE[15:0] DMA_EN_CHI and/or HSI_DMA_D_IRQENABLE[15:0] DMA_EN_CHI	0x-
Enable the DMA full block interrupt event.	DMA_CSR_CCIR_i[5] BLOCK_IE	0x1
Enable the DMA half block interrupt event.	DMA_CSR_CCIR_i[2] HALF_IE	0x1
Enable the DMA time-out overflow interrupt event.	DMA_CSR_CCIR_i[0] TOUT_IE	0x1

#### 23.10.5.1.2.1.5.5 Sub-sequence - DMA Interrupt Servicing

**Table 23-808. Event Servicing in DMA Transmit/Receive Mode**

Step	Register / Bit Field / Programming Model	Value
Identify which DMA channel has generated an interrupt.	HSI_DMA_M_IRQSTATUS[15:0] DMA_CHI and/or HSI_DMA_D_IRQSTATUS[15:0] DMA_CHI	0x-
Identify the interrupt event type.	DMA_CSR_CCIR_i[21] BLOCK_IS and/or DMA_CSR_CCIR_i[18] HALF_IS and/or DMA_CSR_CCIR_i[16] TOUT_IS	0x-
Acknowledge DMA global interrupt by writing 1 into the relevant bit.	HSI_DMA_M_IRQSTATUS[15:0] DMA_CHI and/or HSI_DMA_D_IRQSTATUS[15:0] DMA_CHI	0x-

#### 23.10.5.1.2.1.6 Main Sequence - HSI Error Reporting

**Table 23-809. Enable HSI Error Interrupts**

Step	Register / Bit Field / Programming Model	Value
Enable error detected interrupt.	HSI_Pp_M_IRQrU_ENABLE[24] HSR_ERROR and/or HSI_Pp_D_IRQrU_ENABLE[24] HSR_ERROR and/or HSI_Pp_M_IRQr_ENABLE[24] HSR_ERROR and/or HSI_Pp_D_IRQr_ENABLE[24] HSR_ERROR	0x1

**Table 23-810. Event Servicing Error**

Step	Register / Bit Field / Programming Model	Value
Read interrupt status register.	HSI_Pp_M_IRQrU_STATUS[24] HSR_ERROR and/or HSI_Pp_D_IRQrU_STATUS[24] HSR_ERROR and/or HSI_Pp_M_IRQr_STATUS[24] HSR_ERROR and/or HSI_Pp_D_IRQr_STATUS[24] HSR_ERROR	0x-
Identify the interrupt event type.	HSR_ERROR_Pp[0] SIG HSR_ERROR_Pp[1] FTE HSR_ERROR_Pp[4] FBE HSR_ERROR_Pp[7] RME HSR_ERROR_Pp[11] TME	0x-

**Table 23-810. Event Servicing Error (continued)**

Step	Register / Bit Field / Programming Model	Value
Clear the event by writing 1 into the relevant bit.	HSR_ERRORACK_Pp[0] SIG HSR_ERRORACK_Pp[1] FTE HSR_ERRORACK_Pp[4] FBE HSR_ERRORACK_Pp[7] RME HSR_ERRORACK_Pp[11] TME	0x1
Acknowledge the interrupt by writing 1 into the relevant bit.	HSI_Pp_M_IRQrU_STATUS[24] HSR_ERROR and/or HSI_Pp_D_IRQrU_STATUS[24] HSR_ERROR and/or HSI_Pp_M_IRQr_STATUS[24] HSR_ERROR and/or HSI_Pp_D_IRQr_STATUS[24] HSR_ERROR	0x1

## 23.10.6 HSI Register Manual

### 23.10.6.1 HSI Instance Summary

**Table 23-811. HSI Instance Summary**

Module Name	Module Base Address	Size
HSI_TOP	0x4A05 8000	5 KB
HSI_DMA_CHANNELS	0x4A05 9800	1 KB
HSI_PORTS	0x4A05 A000	8 KB

### 23.10.6.2 HSI\_TOP Registers

#### 23.10.6.2.1 HSI\_TOP Register Summary

**Table 23-812. HSI\_TOP Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	HSI_TOP Physical Address
HSI_REVISION	R	32	0x0000 0000	0x4A05 8000

## 23.11 High-Speed Multiport USB Host Subsystem

This section describes the high-speed (HS) universal serial bus (USB) host subsystem of the device.

### 23.11.1 High-Speed Multiport USB Host Subsystem Overview

---

**NOTE:** Copyright ©2004, 2005, 2006, 2007, 2008 Synopsys, Inc. All rights reserved. Used with permission.

---

The high-speed (HS) universal serial bus (USB) host subsystem consists of several ports and several modes per port. The modes are:

- UTMI+ low pin interface (ULPI)
- ULPI transceiverless link (TLL)
- High-speed interchip (HSIC)
- Serial
- Serial TLL

The HS USB host subsystem is composed of:

- HS multiport USB host controller module
- USBTLL module
- Two HSIC digital front end (DFE) modules

The HS USB host controller contains two quasi-independent host controllers that operate in parallel:

- The EHCI controller, based on the *Enhanced Host Controller Interface (EHCI) specification for USB Release 1.0*, is responsible for HS traffic (480 Mbps), over ULPI/USB 2.0 transceiver macrocell interface (UTMI)
- The OHCI controller, based on the *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*, is responsible for full-speed (FS)/low-speed (LS) traffic (12/1.5 Mbps, respectively), over a serial interface

Each of the two external ports of the HS USB host controller is owned by one of the controllers (EHCI or OHCI) at a given time. Each port can work in several modes:

- When the port is owned by the OHCI (FS) host, the 6-pin internal serial interface is used.
- When the port is owned by the EHCI (HS) host, ULPI or UTMI is used.

The current subsystem does not support all dynamic USB speed negotiations, as expected from a standard USB host port at the same time. It supports:

- HS-only (with external HS physical layer [PHY]/HS TLL mode HSIC) on the EHCI
- FS-/LS-only (with external FS PHY/FS TLL mode) on the OHCI

If an FS peripheral is connected to an HS-port (to an HS ULPI PHY), the HS host subsystem negotiates for FS but cannot transfer control to the FS/LS host controller - the PHY interface is not available.

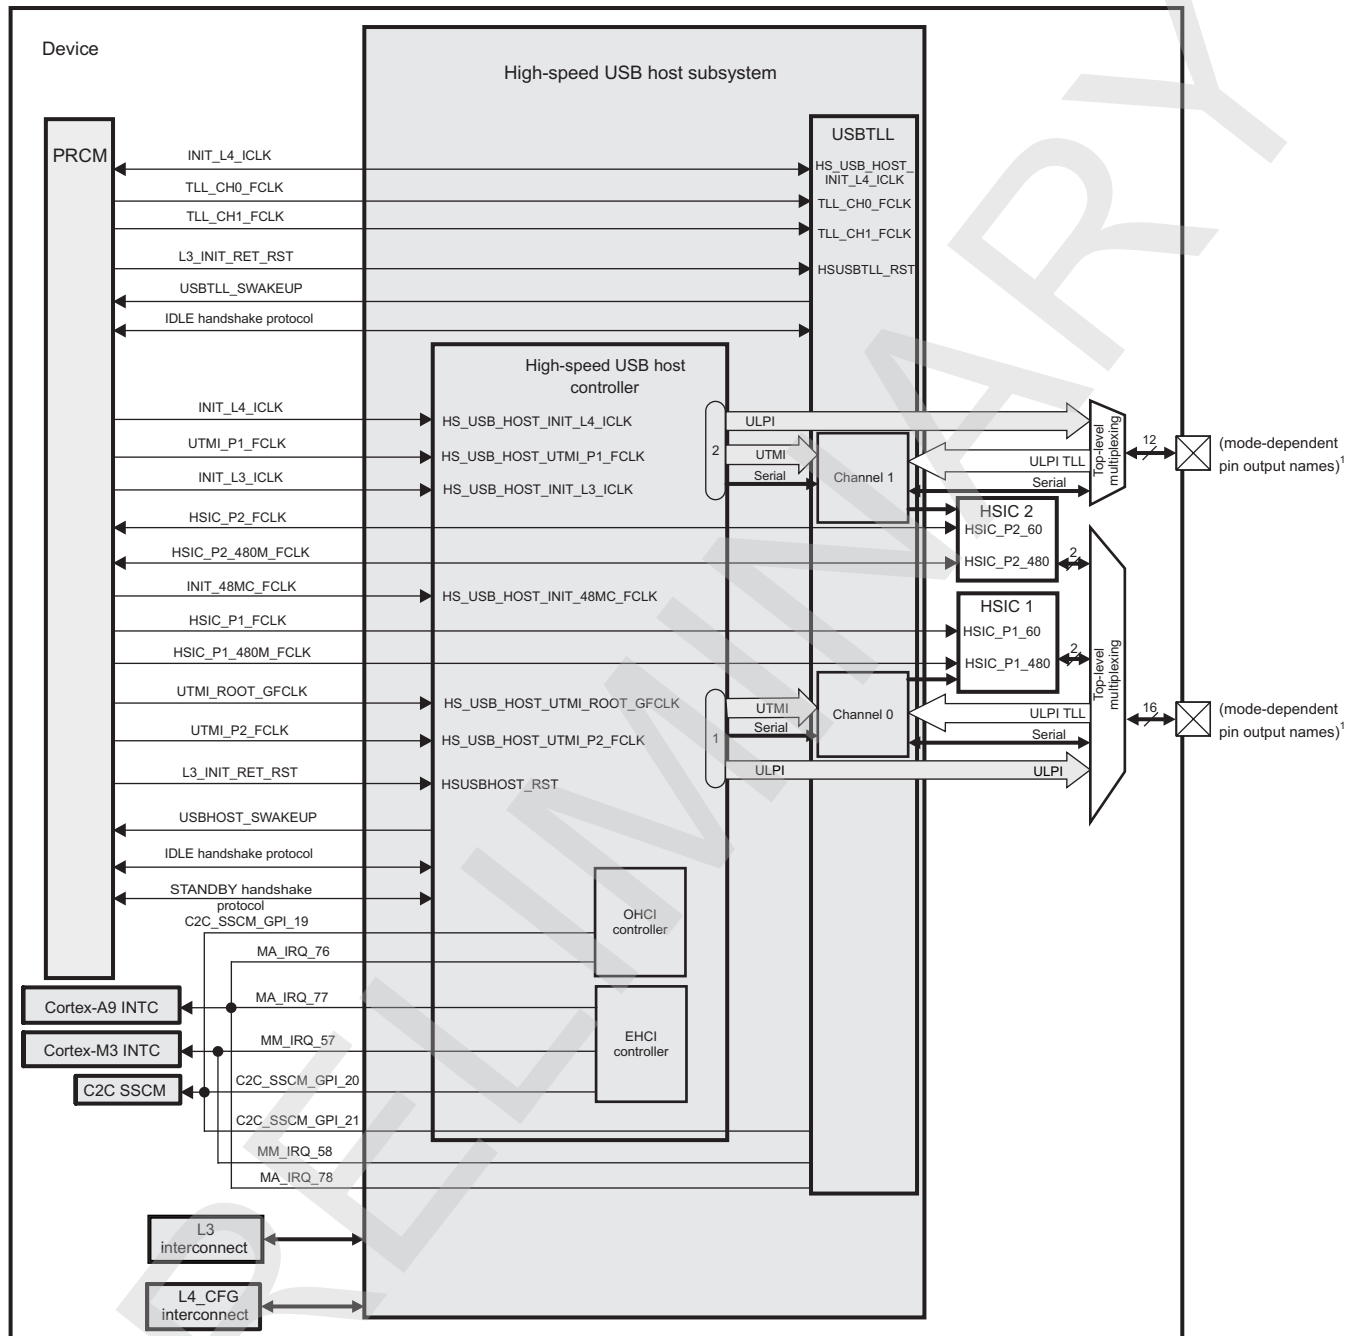

The USBTLL module is the adapter on the host ports. It consists of two channels that are seen as emulating a pair of back-to-back PHYs and has:

- UTMI port, connected to the host
- ULPI port, connected to a ULPI peripheral

The two HSIC DFE plugs into the UTMI port of the host and controls HSIC-capable bidirectional input/output (I/O) drivers driving the HSIC lines (strobe/data).

Figure 23-235 shows the HS USB host subsystem.

Figure 23-235. HS USB Host Controller

usb-006

(1) For more information about output pin names in different modes, see [Section 23.11.2.1, ULPIs](#); [Section 23.11.2.2, FS/LS Serial Interfaces](#); and [Section 23.11.2.3, HSIC Interface](#).

### 23.11.1.1 Main Features

The HS multiport USB host subsystem supports the following features:

- HS USB host controller:
  - One initiator on level 3 (L3)
  - One target on level 4 (L4)
  - Two interrupt requests (IRQs)

- No direct memory access (DMA) request
- Implements a USB 2.0 HS host controller:
  - HS (480 Mbps) communication with HS USB peripherals or hubs
  - FS (12 Mbps) communication with FS USB peripherals or hubs
  - LS (1.5 Mbps) communication with LS USB peripherals
- Support for suspend, resume, remote wakeup
- Two downstream ports (2-port root hub, with each port supporting UTMI, ULPI, and serial interface)
- Heterogeneous port configuration (that is, different HS/FS PHYs with different clocking methods on different ports, supported simultaneously)
- Single FS host controller, compliant with OHCI software application programming interface (API), per-port power switching support
- Interface with UTMI PHYs (transceivers) on all ports
  - 8-bit data path
  - Synchronous (on-chip) interface, independent clock input per port
  - HSIC front-end (after appropriate internal configuration)
- Interface with ULPI PHYs (transceivers) on all ports
  - 8-bit bidirectional data bus (SDR mode)
  - 12-pin interface
  - Independent clock input per port (from ULPI PHY)
  - Supports only HS data transactions

**CAUTION**

The HS USB host subsystem can only supports External Charge pump of PHY (no support of internal charge pump for ULPI PHY)

- Interconnect initiator for built-in DMA operation of EHCI/OHCI
- Interconnect target for configuration
- Link power management (LPM) support in OHCI and EHCI hosts
- Hardware save-and-restore (SAR) feature of the hardware context of the suspended host
- USBTLL module:
  - One interconnect target on L4
  - One IRQ
  - No DMA request
  - HS USB ports and each of them has four ports (A to D):
    - Port A: Host module UTMI+ port. Connected to the local link controller (host module). The UTMI "local" port is used in all configurations (that is, the entire channel can be seen as a protocol converted from that port to one of the other, "remote" ports. The port complies with UTMI+ version 1.0 and supports:
      - 8-data-bit, UTMI (HS/FS-capable)
      - UTMI+ L3 extensions
      - Vcontrol/Vstatus (from UTMI)
      - Serial FS 6-pin mode
    - Port B: Link-side UTMI+ port. Connected to HSIC front-end module.
    - Port C: PHY-side ULPI slave port. Connects to a remote (off-chip) ULPI link controller through I/O pads.
      - SDR ULPI mode (8-bit data width)
      - Supports optional input clocking mode
    - Port D: Serial multimode port.
      - Supports 6-pin unidirectional and 4-/3-/2-pin bidirectional modes
      - All modes are supported for TLL or PHY interface configuration, except 2-pin mode (that is,

TLL-only)

- Supports sideband signals (pullup/down control, speed/suspend enable, etc.)
- HSIC module: Converts UTMI into HSIC standard (2-wire TLL HS protocol)

### 23.11.2 HS Multiport USB Host Subsystem Environment

The HS USB host subsystem provides three kinds of interfaces for connection:

- ULPis for HS data transactions (up to 480 Mbps) (see [Section 23.11.2.1](#), *ULPIs*)
- Serial interfaces, using the USBTLL module, for FS and LS data transactions (up to 12 Mbps) (see [Section 23.11.2.2](#), *FS/LS Serial Interfaces*)
- HSIC interface to two HSIC lines over HSIC-capable I/O drivers (see [Section 23.11.2.3](#), *HSIC Interface*)

[Figure 23-236](#) is an overview of the environment of the HS USB host subsystem.

**Figure 23-236. HS Multiport USB Host Subsystem Environment**

usb\_swpu140-072

- (1) For more information about output pin names in different modes, see [Section 23.11.2.1](#), *ULPIs*; [Section 23.11.2.2](#), *FS/LS Serial Interfaces*; and [Section 23.11.2.3](#), *HSIC Interface*.

**NOTE:** The two ports are configured independently and can be in different modes.

For more information how the pins are multiplexed, see [Section 18.4.8](#), *PAD Functional Multiplexing and Configuration*.

#### 23.11.2.1 ULPIs

The HS USB host subsystem supports the following configurations with the ULPIs:

- External USB transceiver:
  - ULPIs: 12-pin/8-bit data SDR version
- TLL:
  - SDR ULPI mode (12-pin/8-bit data width)

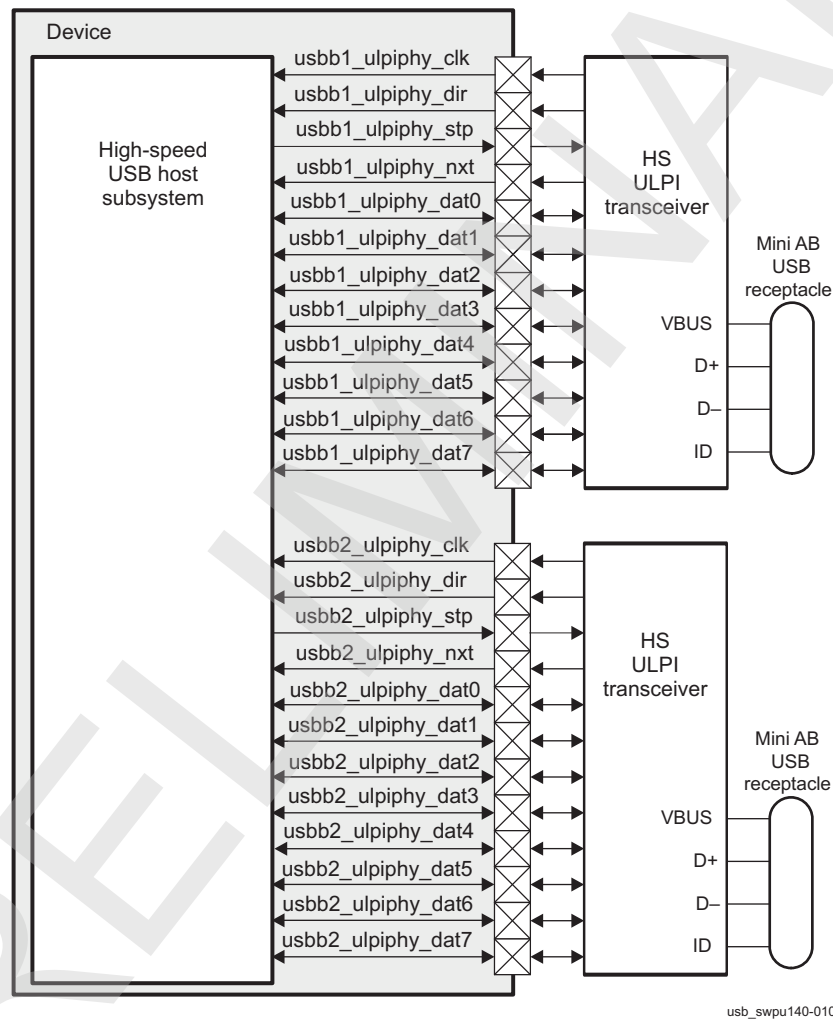

The HS USB host subsystem supports USB ports that use the ULPI mode to connect to an off-chip HS ULPI transceiver (12-pin/8-bit data SDR mode) for data transactions (up to 480 Mbps). FS and LS are not supported over the ULPI.

The device supports TLL logic interfaces on its ports in ULPI TLL interface mode. TLL modes enable glueless interconnect to another USB device port.

The external USB transceiver ULPIs and ULPI TLL interfaces cannot be used together on the same port. It is possible for one port to use ULPI and the other port to use ULPI TLL.

Figure 23-237 and Figure 23-238 show typical applications using the HS USB host subsystem with ULPI and the ULPI TLL interface, respectively.

Figure 23-237. External USB Transceiver ULPIs

**Figure 23-238. ULPI TLL Interfaces**

usb\_swpu140-032

The 12-pin ULPI uses an 8-bit data bus with data synchronous to the rising edge of the PHY (transceiver) clock (SDR mode).

#### 23.11.2.1.1 Transceiver Interface Configuration in ULPI Mode

The HS USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI mode.

[Figure 23-239](#) shows USB ports using the 12-pin/8-bit data SDR version of the ULPI mode.

Figure 23-239. ULPIs - 12-Pin/8-Bit Data SDR Version

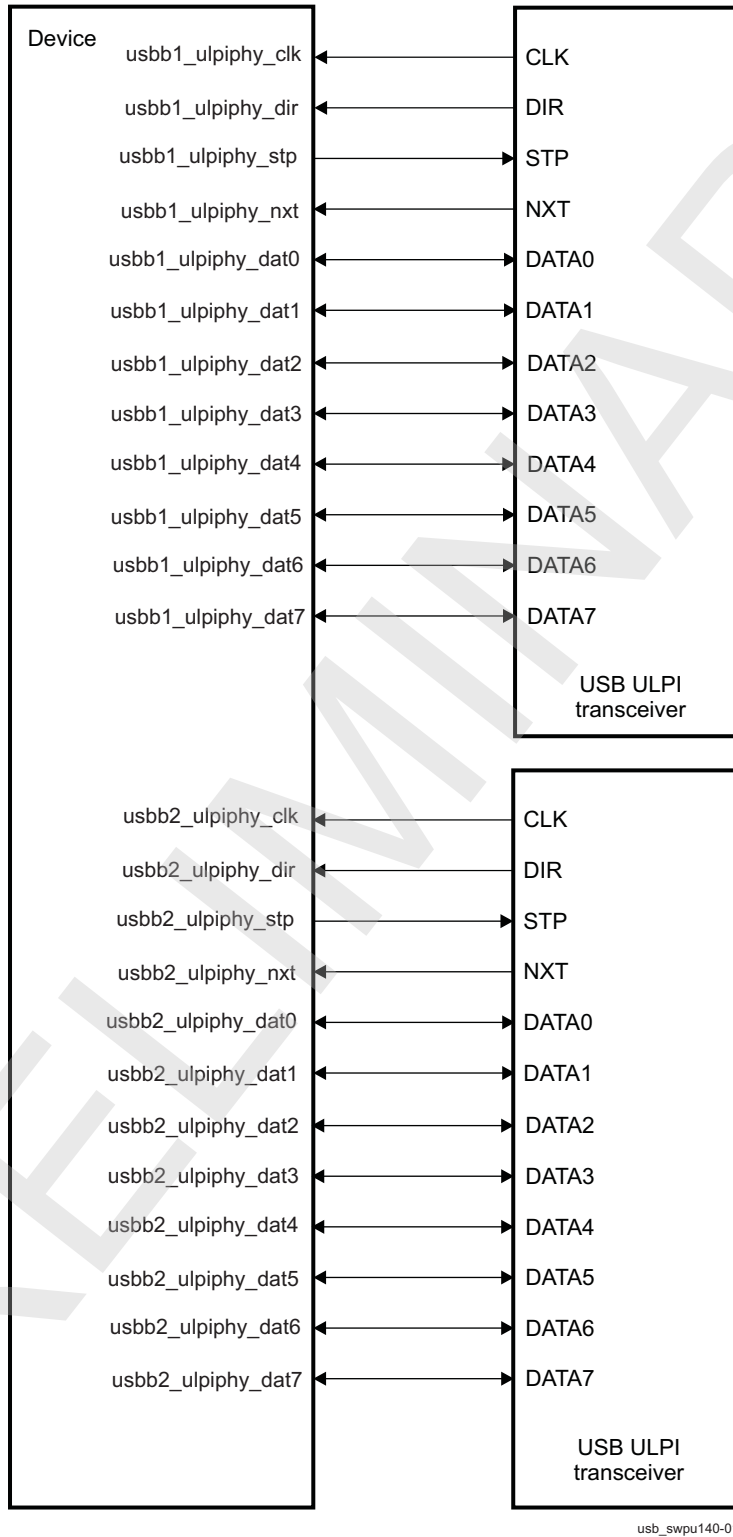

Table 23-927 describes the I/O pins of the USB ports using the 12-pin/8-bit data SDR version of the ULPI mode.

**Table 23-927. ULPI - 12-Pin/8-Bit Data SDR Version I/O Description**

<sup>(1)</sup> I = Input; O = Output

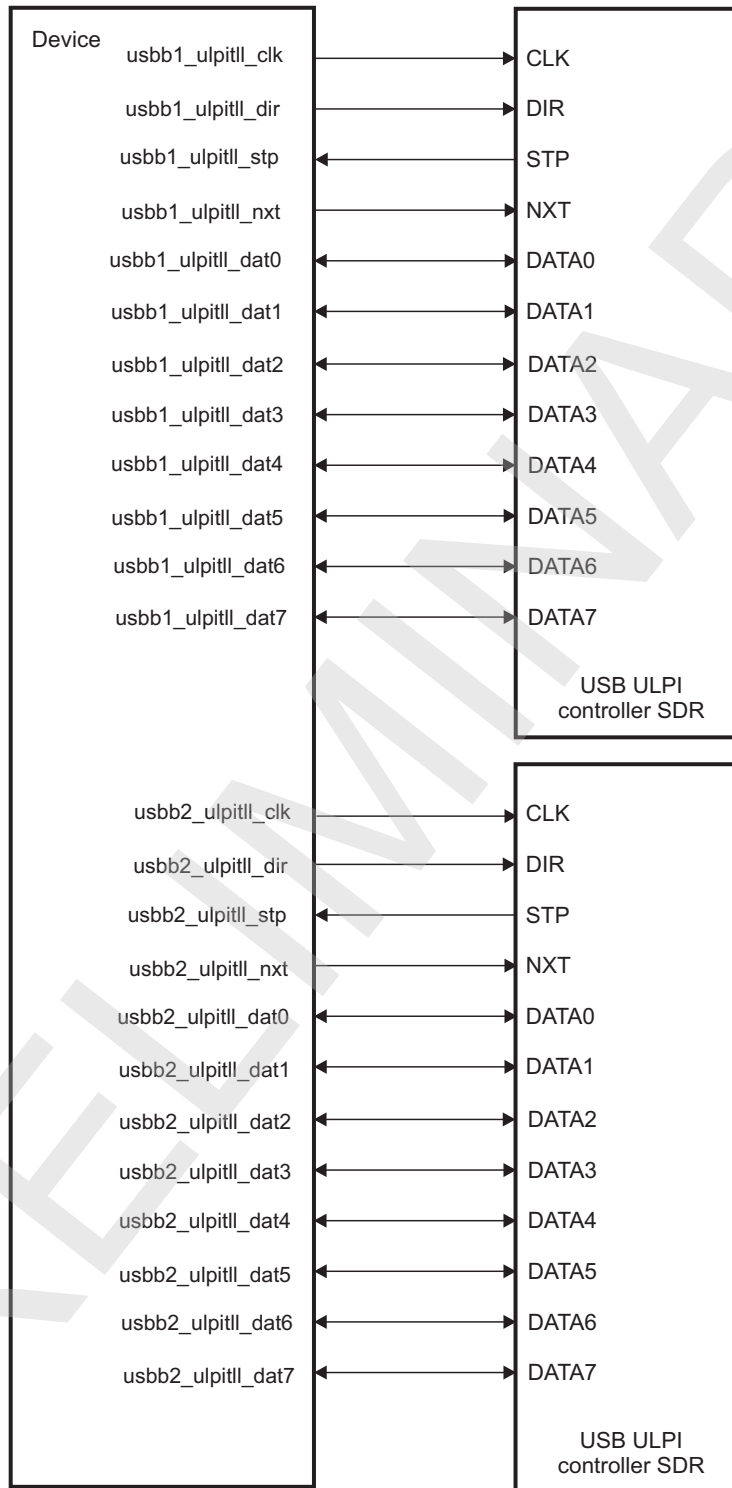

<sup>(2)</sup> This signal is also used as retiming input.

### 23.11.2.1.2 TLL Interface Configuration in ULPI Mode

The HS USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

Figure 23-240 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI TLL interface mode.

Figure 23-240. ULPI TLL Interfaces - 12-Pin/8-Bit Data SDR Version

usb\_swpu140-012

Table 23-928 describes the I/O pins of the USB ports using the 12-pin/8-bit data SDR version of the ULPI TLL interface mode.

**Table 23-928. ULPI TLL Interfaces - 12-Pin/8-Bit Data SDR Version I/O Description**

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
<b>HS USB TLL Port 1</b>			
usbb1_ulpitll_clk	O	Clock output to remote ULPI link controller <sup>(2)</sup>	0
usbb1_ulpitll_dir	O	Data direction control from remote ULPI link controller	0

usbb2_ulpitll_dat6	I/O	Bidirectional DATA6	0
usbb2_ulpitll_dat7	I/O	Bidirectional DATA7	0

<sup>(1)</sup> I = Input; O = Output

<sup>(2)</sup> This signal is also used as retiming input.

### 23.11.2.2 FS/LS Serial Interfaces

The HS USB host subsystem supports the following configurations with the serial interfaces:

- External USB transceiver (see [Section 23.11.2.2.3, External USB Transceiver Interface Configurations in Serial Modes](#))
  - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)
- TLL (see [Section 23.11.2.2.4, TLL Interface Configurations in Serial Modes](#))
  - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

#### CAUTION

Only FS and LS data transactions are possible in serial mode. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

Whether in TLL or external transceiver configuration, the serial interface follows the same principles: it is limited to FS/LS, and HS requires a parallel interface.

23.11.2.2.1 Encoding in Serial Mode

23.11.2.2.1.1 Unidirectional

When an external USB transceiver is connected to the device and is used in 6-pin unidirectional DAT/SE0 encoding mode, the encoding described in [Table 23-929](#) is used.

**Table 23-929. Signaling Between HS USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DAT/SE0 Signaling)**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
TXEN	Output	Input	When low, the USB transceiver drives D+ and D-.				
DAT and SE0	Output	Input	Controls the values output by the USB transceiver on D+ and D- when TXEN is low; ignored when TXEN is high.				
			TXEN	DAT	SE0	D+	D-
			0	0	0	0	1
			0	1	0	1	0
			0	X	1	0	0
1	X	X	Undriven	Undriven			
RCV	Input	Output	Output from transceiver differential receiver				
			D+	D-	RCV		
			0	0	X		
			0	1	0		
			1	0	1		
1	1	X					
DP	Input	Output	Output from transceiver single-ended D+ signal receiver				
			D+	DP			
			0	0			
1	1						
DM	Input	Output	Output from transceiver single-ended D- signal receiver				
			D-	DM			
			0	0			
1	1						

When an external USB transceiver is connected to the device and is used in 6-pin unidirectional DP/DM encoding mode, the encoding described in [Table 23-930](#) is used.

**Table 23-930. Signaling Between HS USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DP/DM Signaling)**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
TXEN	Output	Input	When low, the USB transceiver drives D+ and D-.				
DAT and SE0	Output	Input	Controls the values output by the USB transceiver on D+ and D- when TXEN is low; ignored when TXEN is high.				
			TXEN	DAT	SE0	D+	D-
			0	0	1	0	1
			0	1	0	1	0
			0	0	0	0	0
1	X	X	Undriven	Undriven			

**Table 23-930. Signaling Between HS USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DP/DM Signaling) (continued)**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description		
RCV	Input	Output	Output from transceiver differential receiver		
			D+	D-	RCV
			0	0	X
			0	1	0
			1	0	1
1	1	X			
DP	Input	Output	Output from transceiver single-ended D+ signal receiver		
			D+	DP	
			0	0	
1	1				
DM	Input	Output	Output from transceiver single-ended D-signal receiver		
			D-	DM	
			0	0	
			1	1	

### 23.11.2.2.1.2 Bidirectional

When an external USB or USB On-The-GO (OTG) transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 encoding mode, the encoding described in [Table 23-931](#) is used.

**Table 23-931. Signaling Between HS USB Host Subsystem and 3-Pin Bidirectional USB Transceiver Using DAT/SE0 Signaling**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
TXEN	Output	Input	When low, the USB transceiver drives D+ and D-.				
DAT and SE0	Output	Input	When TXEN is low, the device drives DAT and SE0 and the transceiver drives D+ and D- based on the values of DAT and SE0.				
			TXEN	DAT	SE0	D+	D-
			0	0	0	0	1
		1	0	1	0		
		X	1	0	0		
	Input	Output	TXEN	D+	D-	DAT	SE0
			1	0	0	0	1
				0	1	0	0
				1	0	1	0
			1	1	Undefined	0	

**NOTE:** The device does not support 3-wire bidirectional signaling using DP/DM signals.

When an external USB or USB OTG transceiver is connected to the device and is used in 4-pin bidirectional DP/DM encoding mode, the encoding described in [Table 23-932](#) is used.

**Table 23-932. Signaling Between HS USB Host Subsystem and 4-Pin Bidirectional USB Transceiver Using DP/DM Signaling**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description
TXEN	Output	Input	When low, the USB transceiver drives D+ and D-.

**Table 23-932. Signaling Between HS USB Host Subsystem and 4-Pin Bidirectional USB Transceiver Using DP/DM Signaling (continued)**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description		
DM	Output	Input	Value driven to or received from D-		
			TXEN	DM	D-
			0	0	0
	0	1	1		
	Input	Output	TXEN	D-	DM
			1	0	0
1			1	1	
DP	Output	Input	Value driven to or received from D+		
			TXEN	DP	D+
			0	0	0
	0	1	1		
	Input	Output	TXEN	D+	DP
			1	0	0
1			1	1	
RCV	Input	Output	Output from transceiver differential receiver		
			D+	D-	RCV
			0	0	X
			0	1	0
			1	0	1
			1	1	X

**23.11.2.2.2 Sideband Signals for Serial Modes**

Serial interfaces carry only the USB data information. Sideband control and status (respectively, to/from the transceiver/TLL or to the bus lines themselves) require additional signals, which are usually implemented in a case-by-case, ad hoc way.

- Sideband control examples: FS/LS (slew rate control), transceiver suspend, connect (D+/D- pullup), pulldown enable, VBUS drive, etc.
- Sideband status example: VBUS level (VBUS valid, session valid, session end, etc.)
- Sideband signal implementations: Dedicated lines (one per sideband information bit), serial bus + interrupt line with register-mapped control/status (inter-integrated circuit [I<sup>2</sup>C™], universal asynchronous receiver/transmitter [UART], etc.)

Figure 23-241 and Figure 23-242 show system integration for sideband signals for two logically identical USB connections: one in transceiver configuration and one in TLL configuration. Although the sideband (purple) arrows are oriented from the controller to the transceiver in the two figures, the sideband information flow is bidirectional (that is, it flows from the controller to the transceiver [control] and from the transceiver to the controller [status]).

Figure 23-241 shows the transceiver configuration, where each side connects the sideband signals to its own transceiver. On the device (containing the USBTLL module), the sideband is decoded/re-encoded. The sideband signals available at the device boundary (and the USBTLL module) are decoded from the standard UTMI+ interface.

- The software-driven VBUS reporting procedure is described in Section 23.11.4.2.6.1.1, *VBUS Management in Serial Transceiver Configurations*.

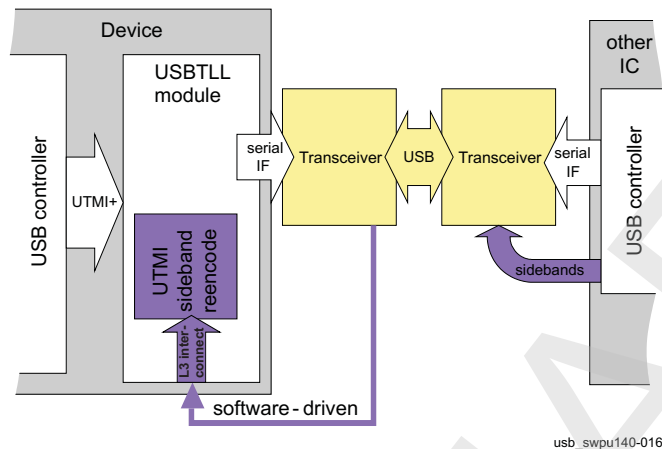

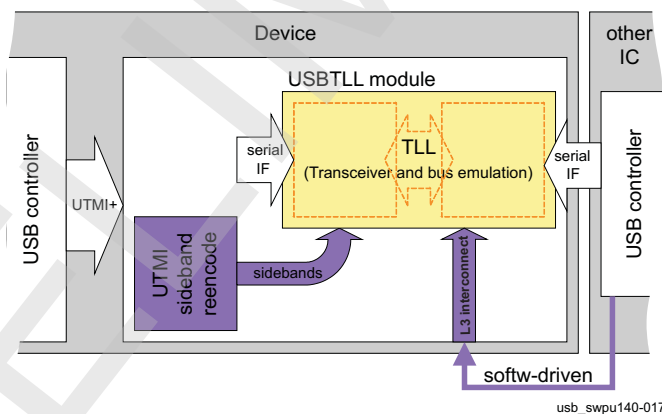

**Figure 23-241. Serial Interface Sideband Integration - Transceiver Configuration**

Figure 23-242 shows the TLL configuration, where both transceivers are emulated inside the USBTLL module.

- The transceiver of the local controller (left side of the figure) is working with the sideband information to/from the UTMI+ port. This is internal to the USBTLL module.
- The transceiver of the remote controller (right side of the figure) must communicate with its controller, which is on another IC. This is done in two ways:
  - The sideband input signals at the TLL module boundary (tlpven, tldrsvbus, tlsvbusvalid, etc.)
  - The software-driven VBUS control procedure described in [Section 23.11.4.2.6.2.2, VBUS Emulation in Serial TLL Modes](#))

**Figure 23-242. Serial Interface Sideband Integration - TLL Configuration**

### 23.11.2.2.3 External USB Transceiver Interface Configurations in Serial Modes

An external USB transceiver is required for each USB port used in the system. It converts between appropriate signaling for the HS USB host subsystem and appropriate signaling for the USB wire.

The serial interface mode of the HS USB host subsystem includes support for several types of USB transceivers. It provides signaling to up to two external USB transceivers.

Several types of external transceiver signaling are supported. Signaling between the HS USB subsystem in serial interface mode and the external USB transceiver for monitoring and controlling the differential USB signal can be done through a 6-, 4-, or 3-wire signaling interface, with two or more control signals provided by additional signals or through an I<sup>2</sup>C link.

The following subsections describe the transceiver interface modes supported by the HS USB host subsystem in the serial interface mode. In each case, the subsystem is connected to external transceivers, on the other side of the USB lines (D+/D-).

**23.11.2.2.3.1 Unidirectional Transceiver Interface Modes: 6-Pin**

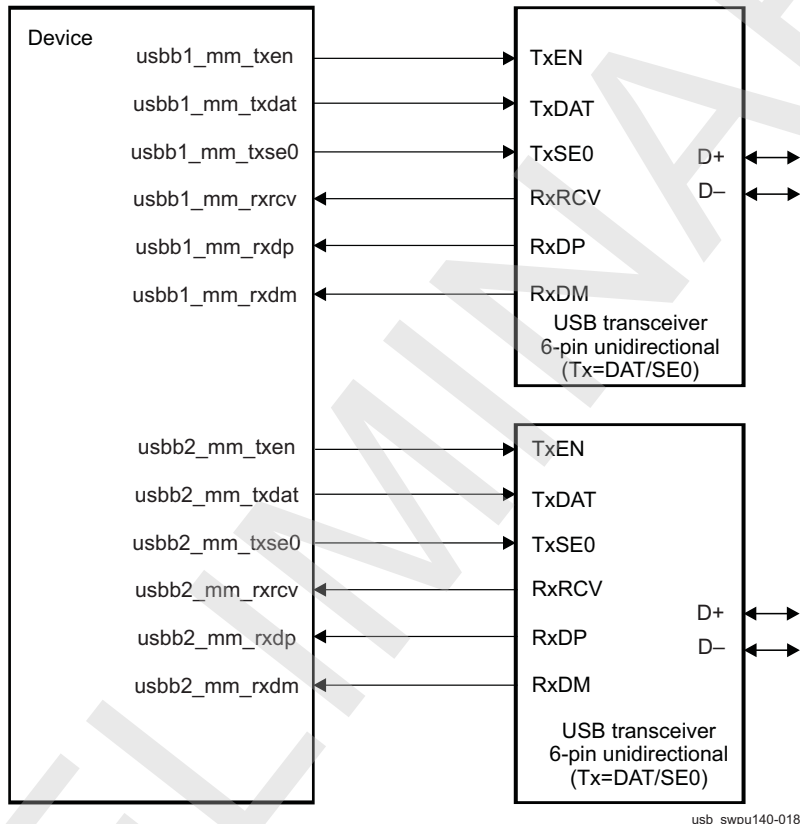

The 6-pin modes are the "natural" transceiver interface modes for the FS transceivers in the sense that they mirror the internal makeup of the transceivers.

Two encodings exist for TX: DAT/SE0 and DP/DM.

When an external USB is connected to the device and is used in 6-pin unidirectional DAT/SE0 signaling mode, the signaling described in [Table 23-929](#) is used.

[Figure 23-243](#) shows a USB port using DAT/SE0 encoding.

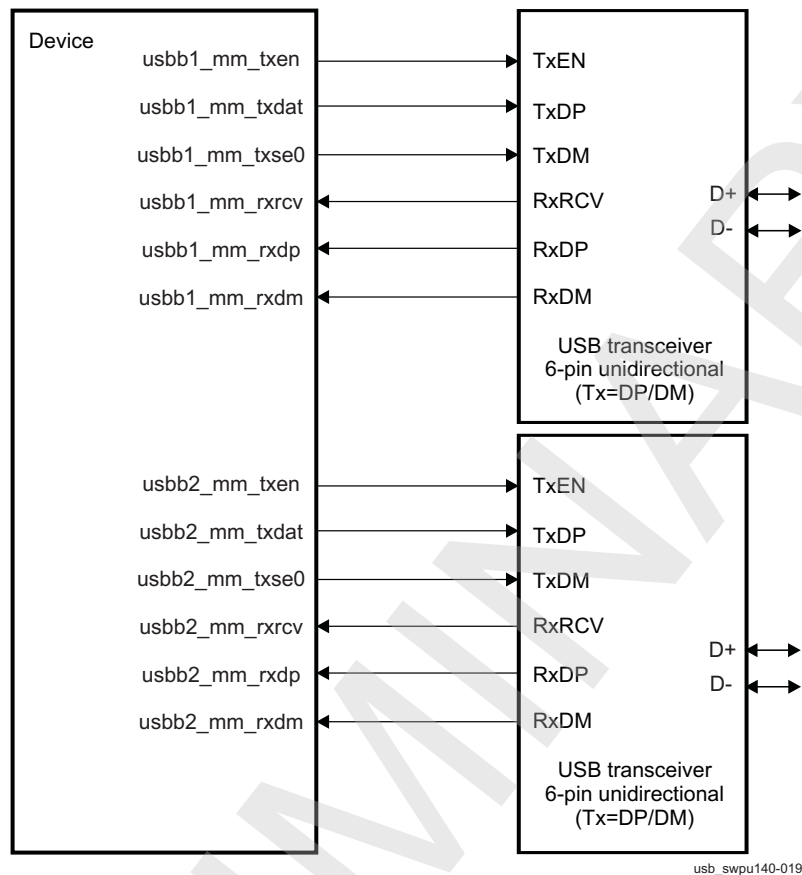

**Figure 23-243. 6-Pin Unidirectional Using DAT/SE0 Signaling**

usb\_swpu140-018

When a USB is connected to the device and is used in 6-pin unidirectional DP/DM signaling mode, the signaling described in [Table 23-930](#) is used.

[Figure 23-244](#) shows a USB port using DP/DM encoding.

**Figure 23-244. 6-Pin Unidirectional Using DP/DM Signaling**

### 23.11.2.2.3.2 Bidirectional Transceiver Interface Modes: 3-Pin, 4-Pin

The bidirectional transceiver interface modes are pin-count optimizations of the unidirectional modes. They take advantage of the fact that a USB port is sending or receiving at any given time, but never both. The TX and RX paths of the unidirectional mode can be multiplexed on bidirectional lines. To prevent glitches at TX/RX turnaround, the same encoding is used for both directions (DAT/SE0 or DP/DM).

The signaling listed in [Table 23-931](#) is used when a USB transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 signaling mode.

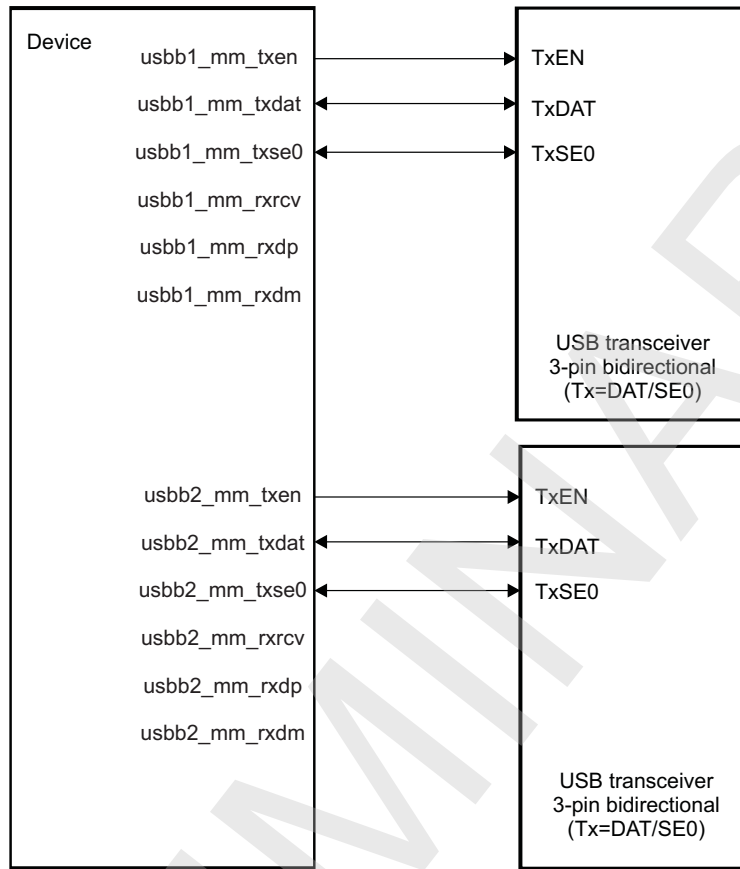

---

**NOTE:** The device does not support 3-wire bidirectional signaling using DP/DM signals.

---

[Figure 23-245](#) shows a USB port using DAT/SE0 encoding.

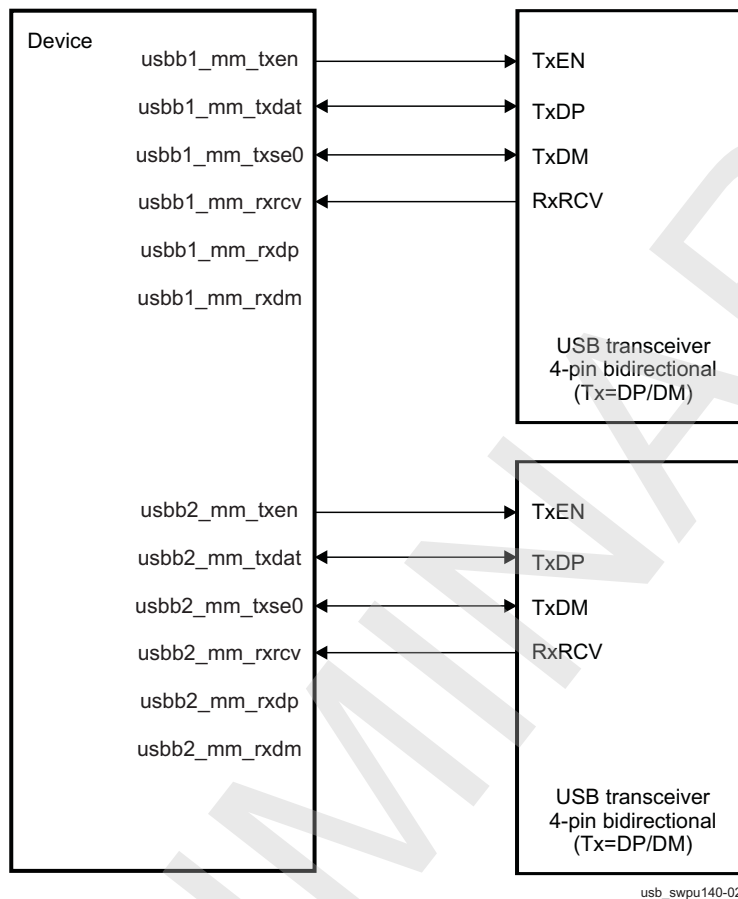

**Figure 23-245. 3-Pin Bidirectional Using DAT/SE0 Signaling**

usb\_swpu140-020

The signaling listed in [Table 23-932](#) is used when a USB transceiver is connected to the device and is used in 4-pin bidirectional DP/DM signaling mode.

[Figure 23-246](#) shows a USB port using DP/DM encoding.

**Figure 23-246. 4-Pin Bidirectional Using DP/DM Signaling**

#### 23.11.2.2.4 TLL Interface Configurations in Serial Modes

The HS USB host subsystem supports unidirectional and bidirectional TLL logic interfaces on its ports. The TLL modes enable glueless interconnect to the USB device port of another device without needing a costly transceiver.

Serial interface modes are FS or LS only. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

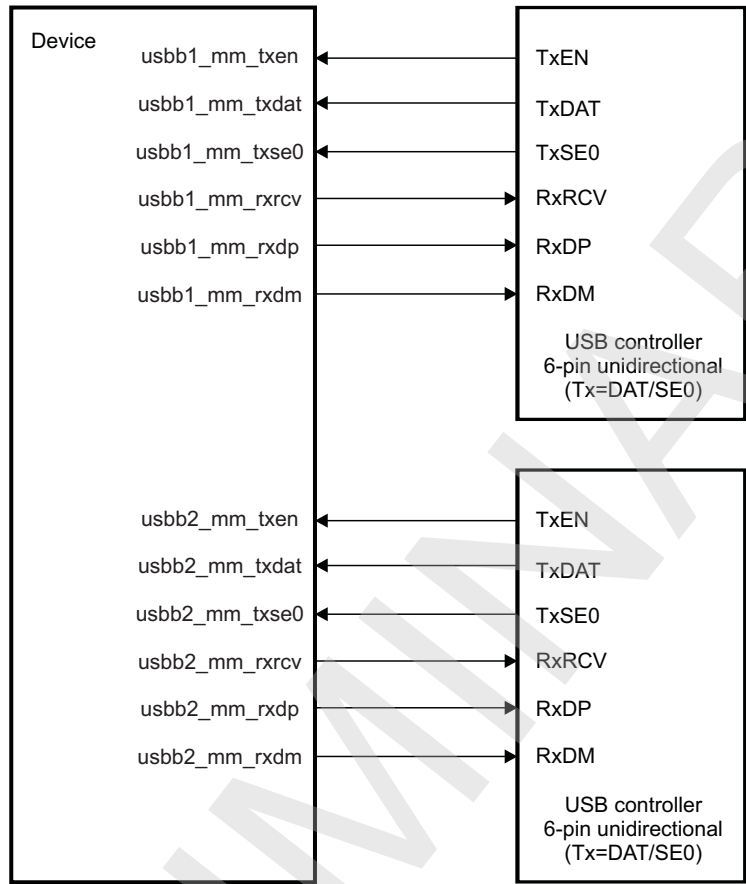

##### 23.11.2.2.4.1 Unidirectional TLL Serial Modes

The 6-pin TLL configurations are mirror images of the 6-pin transceiver configurations previously discussed. The same signals are mapped on the same physical pins, but in opposite directions.

Two possible modes exist, depending on the TX data encoding used by the external device.

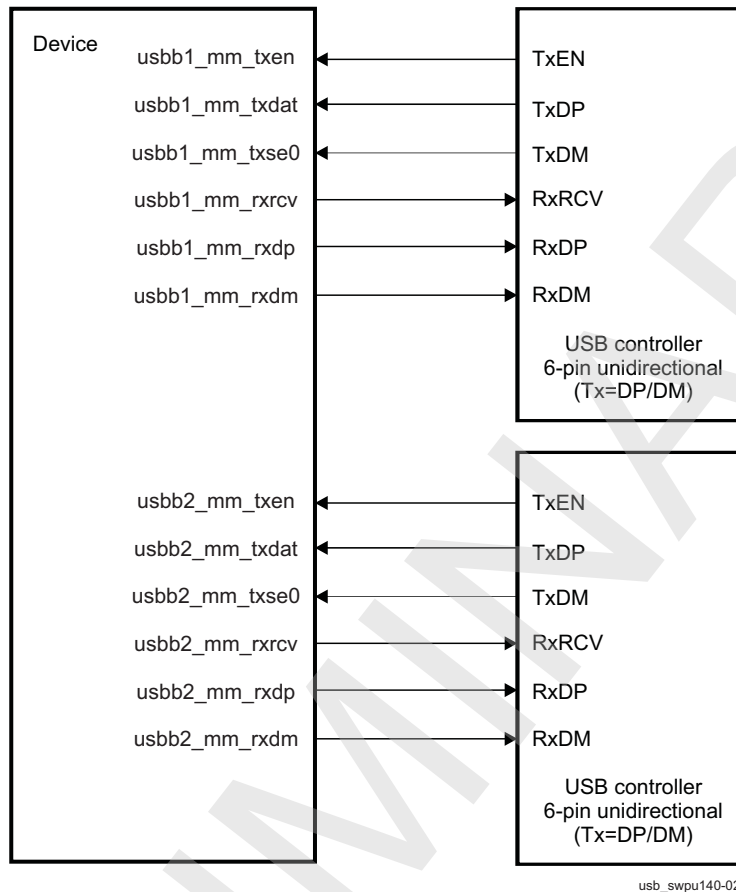

[Figure 23-247](#) shows an external device using DAT/SE0 encoding.

Figure 23-247. 6-Pin Unidirectional TLL Using DAT/SE0 Signaling

usb\_swpu140-022

Figure 23-248 shows an external device using DP/DM encoding.

**Figure 23-248. 6-Pin Unidirectional TLL Using DP/DM Signaling****23.11.2.2.4.2 Bidirectional TLL Serial Modes**

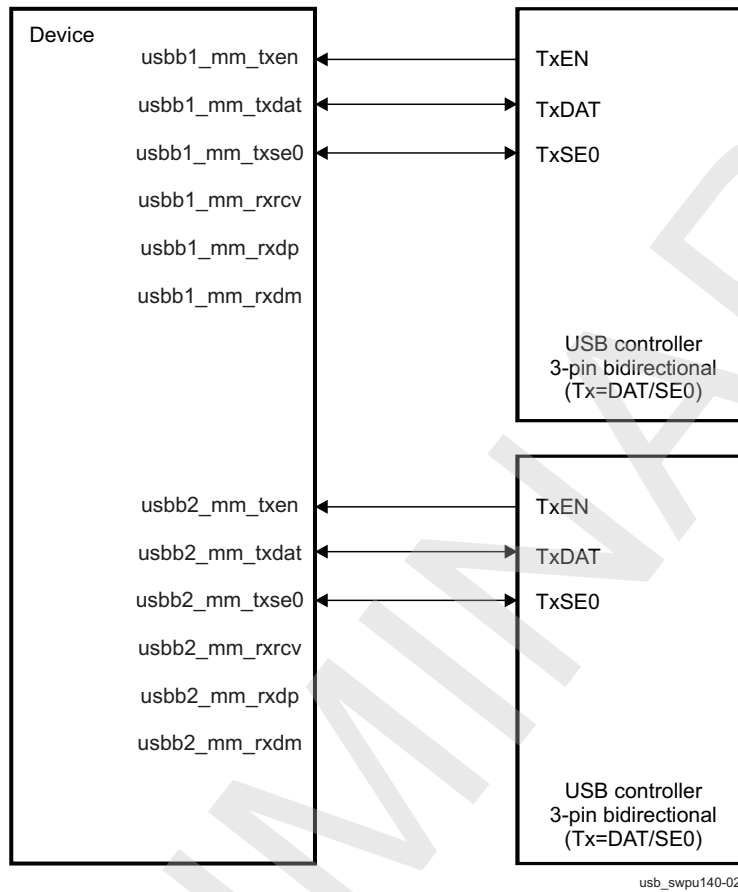

The 3-pin/4-pin TLL configurations are mirror images of the 3-pin/4-pin transceiver configurations previously discussed. The same signals are mapped on the same physical pins, but in opposite directions (bidirectional lines remain bidirectional).

Two possible modes exist, depending on the TX data encoding used by the external device.

[Figure 23-249](#) shows an external device using DAT/SE0 encoding.

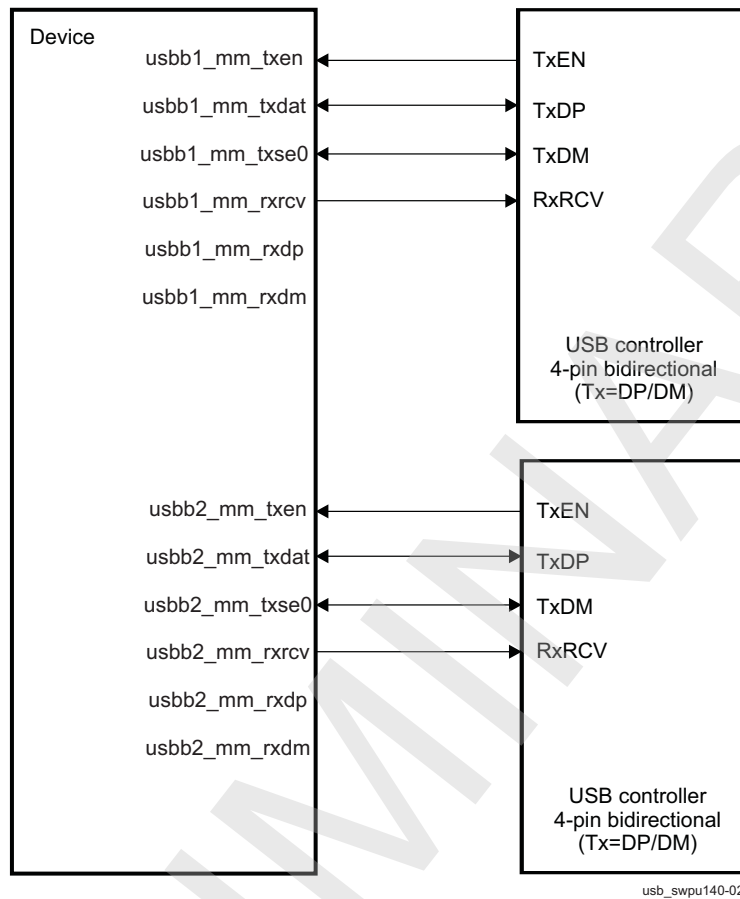

**Figure 23-249. 3-Pin Bidirectional TLL Using DAT/SE0 Signaling**

usb\_swpu140-024

Figure 23-250 shows an external device using DP/DM encoding.

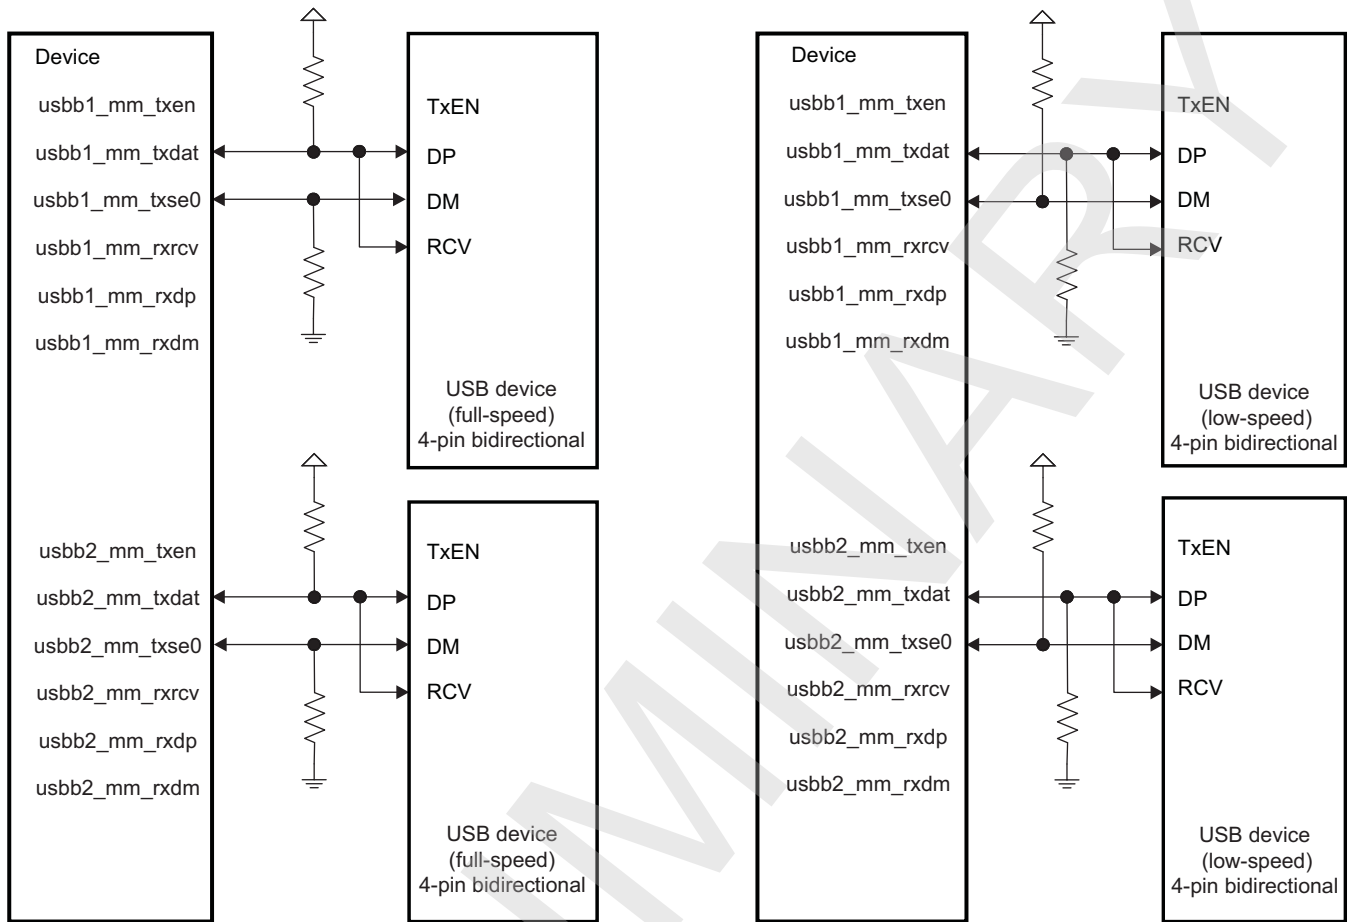

**Figure 23-250. 4-Pin Bidirectional TLL Using DP/DM Signaling**

The 2-pin TLL configurations have unique specifications:

- They require pullups/pulldowns to operate, because the bidirectional lines are not driven at all times like the other serial transceiver interfaces described previously. The connection of pull resistors depends on the speed of the controller.
- The module supports explicit 2-pin TLL modes, with DAT/SE0 or DP/DM encoding.
- Non-TLL modes (that is, transceiver configuration mode) can be used to implement the 2-pin functionality, using a specific connectivity.

Figure 23-251 shows a USB port using DP/DM encoding.

usbb2_mm_rxdm	I	Single-ended DM receiver signal input in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM or 2-pin bidirectional TLL modes)	Unknown
	O	Single-ended DM receiver signal output in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 2-pin bidirectional TLL modes)	

**NOTE:** ULPI (PHY) Interfaces and ULPI TLL Interfaces can not be used together: either the ULPI (PHY) Interfaces or the ULPI TLL Interfaces are selected

### 23.11.2.3 HSIC Interface

The HS USB host subsystem supports the configurations with the HSIC interfaces shown in [Figure 23-253](#).

**Figure 23-253. HSIC Interface**

[Table 23-936](#) describes the I/O of the HSIC interface of the HS USB host subsystem.

**Table 23-936. HSIC Interface**

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
<b>HSUSB HSIC1</b>			
usbb1_hsic_data	I/O	HS interchip data	Unknown

<sup>(1)</sup> I = Input; O = Output

**Table 23-936. HSIC Interface (continued)**

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
usbb1_hsic_strobe	I/O	HS interchip strobe	Unknown
<b>HSUSB HSIC2</b>			
usbb2_hsic_data	I/O	HS interchip data	Unknown
usbb2_hsic_strobe	I/O	HS interchip strobe	Unknown

### 23.11.3 HS Multiport USB Host Subsystem Integration

This section describes the integration of the HS USB host subsystem, including information about clocks, resets, and hardware requests.

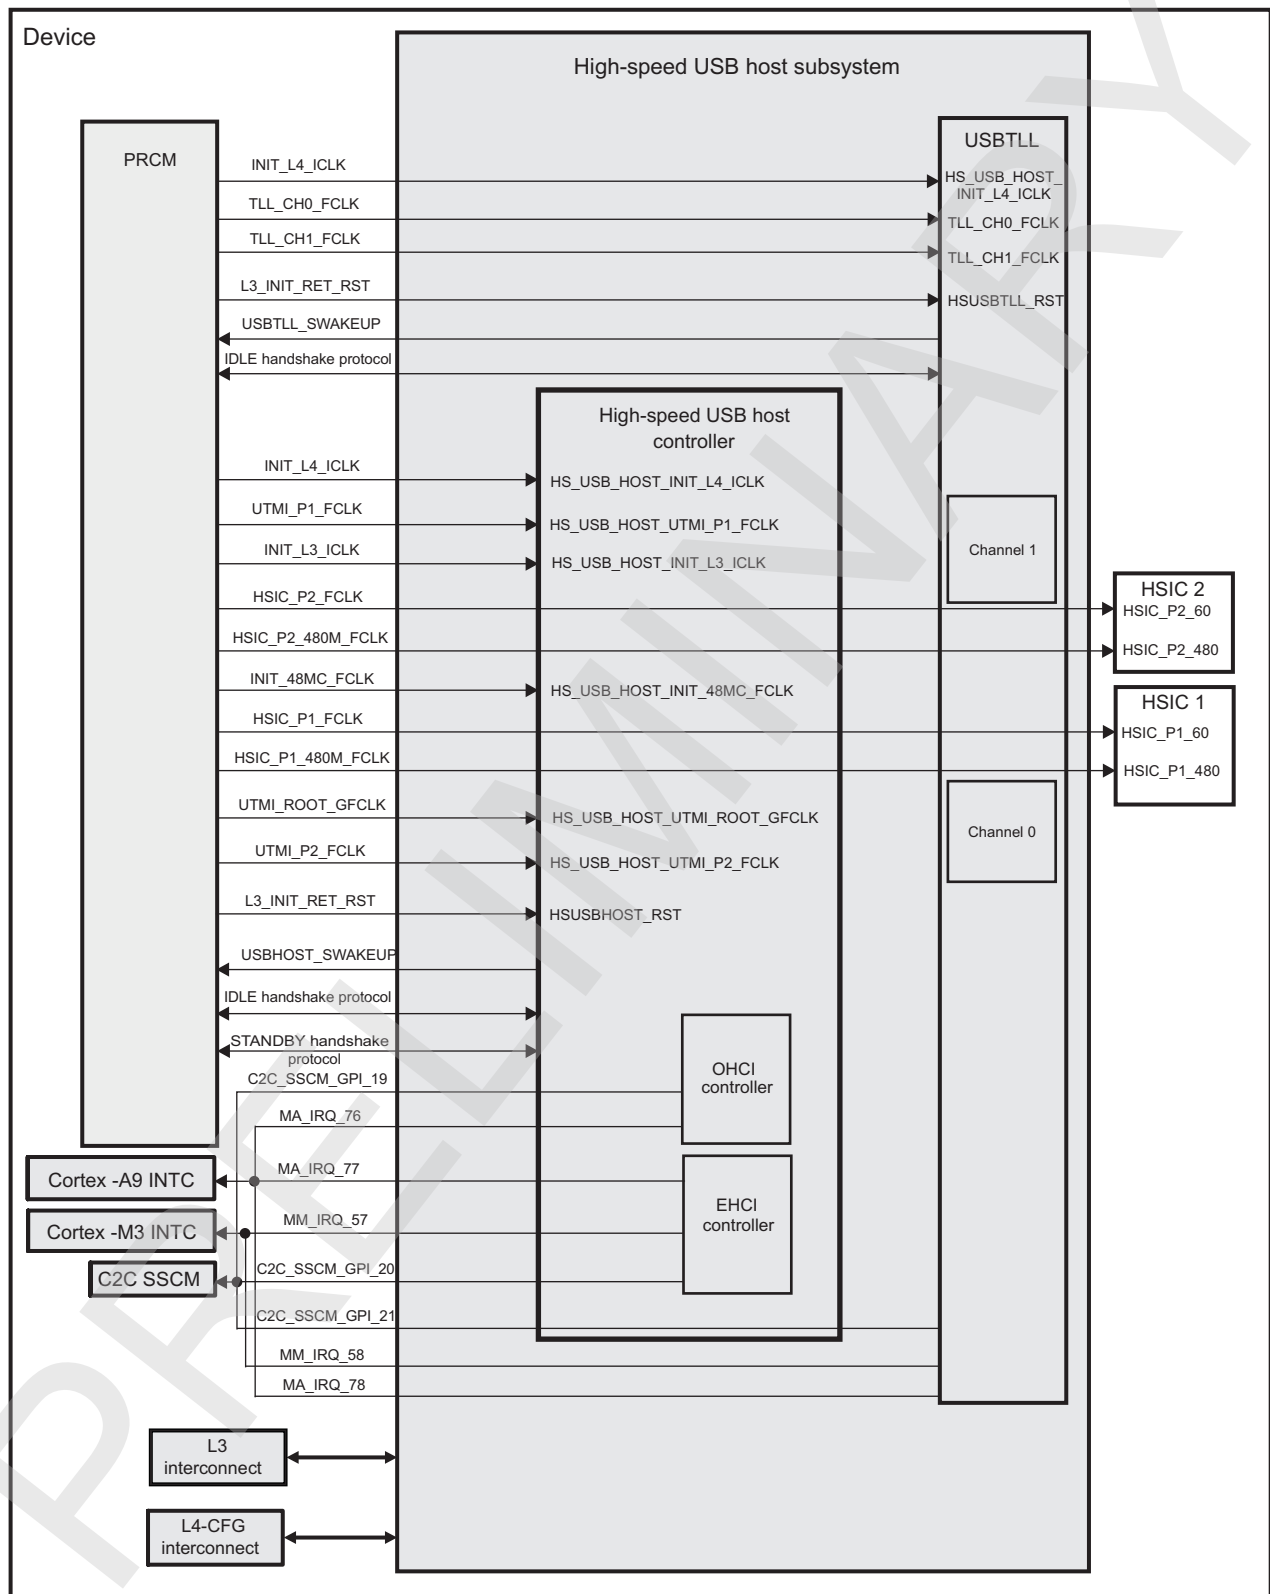

The USB host controller module includes other modules and additional logic attached to the UTMI/ULPI ports. The HS USB host controller is connected to the L3 interconnect master (initiator) and L4\_CFG interconnect slave (target) interfaces.

The elements of the USB HS host subsystem are:

- The multiport USB host controller. Each port uses one of the following modes:
  - ULPI, to a ULPI PHY (typically, off-chip)
  - UTMI, to a local UTMI (typically, on-chip) PHY or emulation of a PHY
- A local phase-locked loop (PLL), able to provide the USB-grade 48-, 60-, 480-MHz clocks
- Two TLL channels, bundled inside a USBTLL module. Each HS TLL channel can be seen as emulating a pair of back-to-back PHYs, and has:
  - A UTMI port, connected to a controller port (the host, in this case)
  - A ULPI port, connected to a (typically, off-chip) ULPI controller (peripheral, in this case)
- Two HSIC DFEs. The DFE plugs into the UTMI port of an HSIC-capable controller (the host, in this case), and controls HSIC-capable bidirectional I/O drivers driving the HSIC lines (strobe/data).

Figure 23-254 shows the HS USB subsystem integration.

Figure 23-254. HS USB Subsystem Integration

usb\_swpu140-028

Table 23-937 through Table 23-939 summarize the integration of the module in the device.

**Table 23-937. Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
HSUSBHOST	PD_L3_INIT	L3 L4_CFG
HSUSBTLL	PD_L3_INIT	

**Table 23-938. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
HSUSBHOST	HS_USB_HOST_INIT_L4_ICLK	INIT_L4_ICLK	PRCM	L4 interconnect enable signal for the slave interface on L4 (see <a href="#">Section 3.6.3.2</a> )
	HS_USB_HOST_INIT_L3_ICLK	INIT_L3_ICLK	PRCM	L3 interconnect clock, for the L3 master port interface (see <a href="#">Section 3.6.9</a> )
	HSIC_P2_480	HSIC_P2_480M_FCLK	PRCM	480-MHz clock for the USB HSIC (see <a href="#">Section 3.6.9</a> )
	HS_USB_HOST_UTMI_P1_FCLK	UTMI_P1_FCLK/usb1_ulpiphy_clk	PRCM/external PHY IC	Port 1 UTMI interface functional clock (see <a href="#">Section 3.6.9</a> and <a href="#">Section 3.6.3.2.2</a> )
	HSIC_P1_60	HSIC_P1_FCLK	PRCM	60-MHz clock for the USB HSIC (see <a href="#">Section 3.6.9</a> )
	HSIC_P1_480	HSIC_P1_480M_FCLK	PRCM	480-MHz clock for the USB HSIC (see <a href="#">Section 3.6.9</a> )
	HS_USB_HOST_INIT_48MC_FCLK	INIT_48MC_FCLK	PRCM	48-MHz functional clock for OHCI and EHCI (see <a href="#">Section 3.6.9</a> )
	HSIC_P2_60	HSIC_P2_FCLK	PRCM	60-MHz clock for the USB HSIC (see <a href="#">Section 3.6.9</a> )
	HS_USB_HOST_UTMI_ROOT_GFCLK	UTMI_ROOT_GFCLK	PRCM	60-MHz root hub clock (see <a href="#">Section 3.6.9</a> )
	HS_USB_HOST_UTMI_P2_FCLK	UTMI_P2_FCLK/usb2_ulpiphy_clk	PRCM/external PHY IC	Port 2 UTMI interface functional clock (see <a href="#">Section 3.6.9</a> and <a href="#">Section 3.6.3.2.2</a> )
HSUSBTLL	HS_USB_HOST_INIT_L4_ICLK	INIT_L4_ICLK	PRCM	L4 interconnect enable signal for the slave interface on L4 (see <a href="#">Section 3.6.3.2</a> )
	TLL_CH0_FCLK	TLL_CH0_FCLK	PRCM	Functional clock for channel 0 (see <a href="#">Section 3.6.9</a> )
	TLL_CH1_FCLK	TLL_CH1_FCLK	PRCM	Functional clock for channel 1 (see <a href="#">Section 3.6.9</a> )
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
HSUSBHOST	HSUSBHOST_RST	L3_INIT_RET_RST	PRCM	The signal resets the HSUSBHOST module.
HSUSBTLL	HSUSBTLL_RST	L3_INIT_RET_RST	PRCM	The signal resets the HSUSBTLL module.

**Table 23-939. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
HSUSBHOST	HSUSB_EHCI_IRQ	MA_IRQ_77	Cortex-A9 INTC	Destination is Cortex™-A9 interrupt controller (INTC).
	HSUSB_OHCI_IRQ	MA_IRQ_76	Cortex-A9 INTC	Destination is Cortex-A9 INTC.
	HSUSB_EHCI_IRQ	MM_IRQ_57	Cortex-M3 INTC	Destination is Cortex-M3 INTC.
	HSUSB_OHCI_IRQ	C2C_SSCM_GPI_19	C2C SSCM	Destination is C2C SSCM.
	HSUSB_EHCI_IRQ	C2C_SSCM_GPI_20	C2C SSCM	Destination is C2C SSCM.
HSUSBTLL	HSUSB_TLL_IRQ	MA_IRQ_78	Cortex-A9 INTC	Destination is Cortex-A9 INTC.

**Table 23-939. Hardware Requests (continued)**

	HSUSB_TLL_IRQ	MM_IRQ_58	Cortex-M3 INTC	Destination is Cortex-M3 INTC.
	HSUSB_TLL_IRQ	C2C_SSCM_GPI_21	C2C SSCM	Destination is C2C SSCM.

The HS USB host controller and TLL module are attached to the L3\_INIT\_RET\_RST reset domain. The L3\_INIT\_RET\_RST signal resets the HS USB host controller and TLL module (see [Chapter 3, Power, Reset, and Clock Management](#)).

### 23.11.4 HS Multiport USB Host Subsystem Functional Description

This section describes the functionality of the HS USB host subsystem by describing the HS USB host controller, USBTLL module.

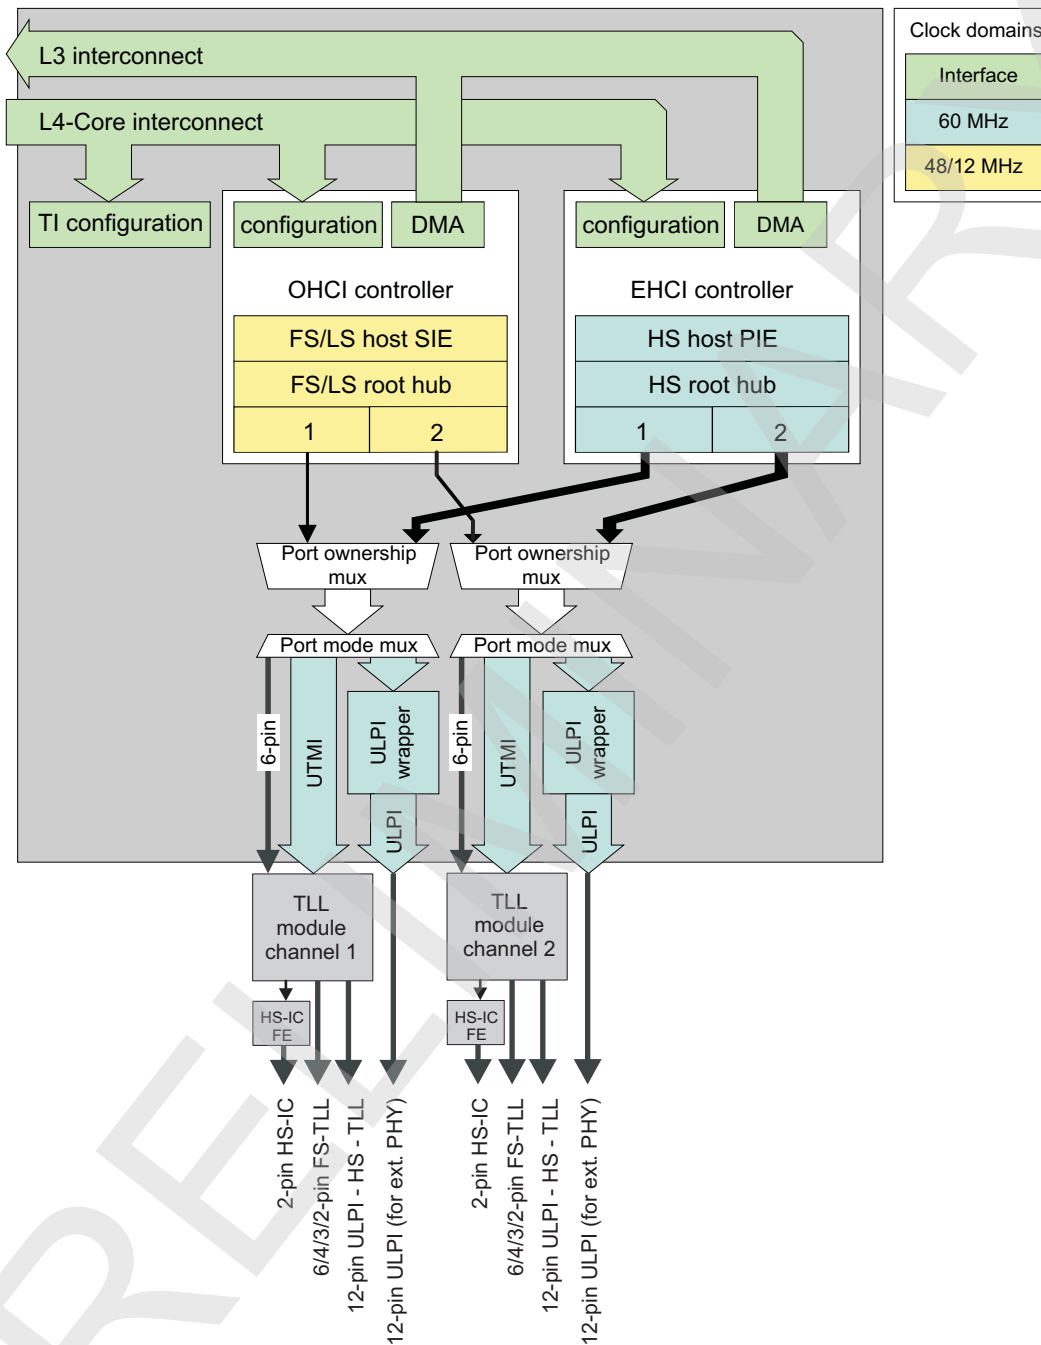

#### 23.11.4.1 USB Host Controller Functionality

The full details of the standard OHCI and EHCI host controller APIs (implemented by the current module) are not repeated here. For more information, see the following specifications:

- *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*
- *Enhanced Host Controller Interface (EHCI) specification for USB Release 1.0*

[Figure 23-255](#) is an overview of the HS USB host controller internal architecture. It contains two independent, 3-port host controllers (OHCI and EHCI) that operate in parallel; however, only two physical ports are mapped in the device processor.

Figure 23-255. HS USB Host Controller Architecture

usb\_swpu140-029

### 23.11.4.1.1 HS USB Host Controller Software Reset

The HS USB host controller has its own software-reset function through the `UHH_SYSCONFIG[0]` `SOFTRESET` bit. Writing 0x1 to this bit resets the HS USB host controller. The bit value of 0x1 remains until the reset completes. When the software reset completes, the `SOFTRESET` bit is automatically set to 0x0 and has the same effect as the hardware reset.

### 23.11.4.1.2 HS USB Host Controller Power Management

The USB protocol defines power-saving modes, where clocks can be shut down. The host asynchronously detects ULPI/UTMI events and asserts the wake-up output, which causes the clocks to restart.

To reduce dynamic power consumption, an efficient idle scheme in the device is based on:

- Efficient local autoclock gating for each module
- Implementation of control sideband signals between the power, reset, and clock management (PRCM) module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without complex software intervention. In both cases, the HS USB host controller power management is applied only to the interface clock domain.

The HS USB host controller has master (initiator) and slave (target) interfaces:

- As an initiator, the HS USB host controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the HS USB host controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

#### 23.11.4.1.2.1 Standby Handshake Protocol

The HS USB host controller can go into standby mode, in which case it stops generating transactions on the interconnect. To save power, the module standby leads the PRCM module to disable the USB clocks.

The HS USB host controller has an Mstandby/Mwait handshake mechanism with the PRCM module (see [Chapter 3, Power, Reset, and Clock Management](#)).

The module is ready to enter standby mode (indicated by the Mstandby signal to the PRCM module asserted) when there is no USB activity and the module is idle. It means:

- The module is committed not to start any new transaction on its master interface.
- The whole module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module go into standby mode based on the [UHH\\_SYSCONFIG\[5:4\] STANDBYMODE](#) bit field.

[Table 23-940](#) lists the settings of standby mode.

**Table 23-940. HS USB Host Controller Standby Mode Settings**

MIDLEMODE Value	Selected Mode	Description
0x0	Force-standby	The HS USB host controller enters standby mode unconditionally (Mstandby is asserted unconditionally).
0x1	No-standby	The HS USB host controller never enters standby mode (Mstandby is never asserted).
0x2	Smart-standby	The HS USB host controller is ready to enter standby mode (Mstandby is asserted) when there is no more activity on the USB master interface of the interconnect.
0x3	Smart-standby + wakeup	The HS USB host controller enters smart mode with asynchronous (master) wakeup enabled.

#### 23.11.4.1.2.2 IDLE Handshake Protocol

The PRCM module handles an IDLE handshake protocol for the HSUSB host controller. The IDLE handshake protocol lets the PRCM module requiring the HS USB host controller to enter idle mode. Although this handshake is completely hardware and out of any software control, the way in which the HS USB host controller acknowledges the PRCM IDLE request is configurable through the [UHH\\_SYSCONFIG\[3:2\] SIDLEMODE](#) bit field. [Table 23-941](#) lists the settings of SIDLEMODE and the related acknowledgment modes.

**Table 23-941. HS USB Host Controller SIDLEMODE Settings**

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The HS USB host controller acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. Because such a mode does not prevent the loss of data when the clock is switched off, the mode must be used carefully.
0x1	No-idle	The HS USB host controller never acknowledges any IDLE request from the PRCM module. This mode is safe from a module point of view because it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off, and thus the power domain to be set to a lower power state.
0x2	Smart-idle	The HS USB host controller acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for an efficient system power management.
0x3	Smart-idle + wakeup	The HS USB host controller enters smart mode with asynchronous (master) wakeup enabled.

#### 23.11.4.1.2.3 Wake-Up Request

The wake-up request signal USBHOST\_SWAKEUP is generated by the HS USB host controller to the PRCM module.

#### 23.11.4.1.3 HS USB Host Controller Save and Restore

The hardware context of the USB HS host can be frozen, saved, and restored.

The SAR mechanism extracts the hardware context of the HS USB host controller (after all USB activity is suspended) before switching off (saving), saves it to an external always-on memory, and reinjects it later after the module has been switched on again and reset (restored) seamlessly for the USB. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

#### 23.11.4.1.4 HS USB Host Controller Port Status

The USB port status is given through the [UHH\\_HOSTCONFIG\[10:8\]](#) bit field. The default value of the following bits is 0x1:

- [UHH\\_HOSTCONFIG\[8\]](#) P1\_CONNECT\_STATUS
- [UHH\\_HOSTCONFIG\[9\]](#) P2\_CONNECT\_STATUS

#### CAUTION

These bits show the port status as connected after power on even though no USB device is connected. The USB host controller has operational status registers (for example [HCRHPORTSTATUS\\_1](#) for the OHCI port 1) that indicate the correct port connect status. The USB driver software must read these status bits and check whether or not a port is connected. If the port is not connected the USB driver software must reprogram the [UHH\\_HOSTCONFIG](#) bits to indicate the correct port connect status.

#### 23.11.4.1.5 HS USB Host Controller Burst Control

To avoid buffer underflow, bursts must be enabled by writing 0x7 in the [UHH\\_HOSTCONFIG\[4:2\]](#) bit field, and the [UHH\\_HOSTCONFIG\[5\]](#) ENA\_INCR\_ALIGN bit must be set to 1.

#### 23.11.4.1.6 OHCI Implementation Specifications

Some features of the OHCI API are optional and/or implementation-specific. The choices made in the current implementation, the HS USB host controller, are described in the following list and are reflected in the register descriptions (see [Section 23.11.6.5, OHCI Registers](#)). For all standard features, see the *Open Host Controller Interface (OHCI) Specification for USB Release 1.0a*.

- **HCFMINTERVAL**[30:16] FSMPS bit field (FullSpeedMaxPacketSize) = 0x0000: The host stops scheduling new packets 0 bit times before the end of the frame (that is, by default, there is no scheduling overrun protection). To be updated by the software driver.
- **HCRHDESCRIPTORA**[7:0] NDP bit field (NumberDownstreamPorts) = 0x03 = three ports
- **HCRHDESCRIPTORA**[9] NPS bit (NoPowerSwitching) = 0: Ports are power-switched by default.
- **HCRHDESCRIPTORA**[8] PSM bit (PowerSwitchingMode) = 1: Per-port power switching is supported, although PPCM default setup has all ports controlled globally.
- **HCRHDESCRIPTORA**[31:24] POTPG bit field (PowerOnToPowerGood) = 0x0A = 10: Power ramp-up time is 10 x 2 ms = 20 ms.
- **HCRHDESCRIPTORB**[15:0] DR bit field (DeviceRemovable) = 0x0000: By default, no nonremovable devices (that is, devices attached to any of the ports) are removable.
- **HCRHDESCRIPTORB**[31:16] PPCM bit field (PortPowerControlMask) = 0x0000: By default, all ports are affected only by global power control.

#### 23.11.4.1.7 UTMI Interface

The host controller supports two ports. Each host controller port is configured to be in UTMI or ULPI mode (see the **UHH\_HOSTCONFIG**[21:16] P<sub>x</sub>\_MODE bit field).

In UTMI mode, a port has its UTMI signal set broadcasting the "outgoing" packets (from the host to the peripherals) and gathering the "incoming" ones (from the addressed peripheral to the host). ULPI signals for that port are undefined/don't care on all ports.

The UTMI ports between the HS USB host controller and the USBTLL module are on-chip and remain invisible.

UTMI transparent mode is used to connect with the HSIC, (see the **UHH\_HOSTCONFIG**[17:16] P1\_MODE or **UHH\_HOSTCONFIG**[17:16] P2\_MODE bit fields).

#### 23.11.4.1.8 ULPI Interface

The host supports two ports. Each host controller port is configured to be either in UTMI or in ULPI mode (see the **UHH\_HOSTCONFIG**[17:16] P1\_MODE or **UHH\_HOSTCONFIG**[17:16] P2\_MODE bit fields).

In ULPI mode, a port has its ULPI signal set broadcasting the outgoing packets (that is, from the host to the peripherals) and gathering the incoming packets (that is, from the addressed peripheral to the host). UTMI signal sets are undefined/don't care on all ports.

---

**NOTE:** The ULPI clock (part of the 12-wire ULPI interface) is expected to be routed by the system from the ULPI CLK input I/O pad to the clock input used by all HS modes (ULPI and UTMI) for the current port. [Section 3.6.3.2.2](#)

---

### 23.11.4.2 USBTLL Module Functionality

#### 23.11.4.2.1 USBTLL Software Reset

Writing 0x1 to the **USBTLL\_SYSCONFIG**[1] SOFTRESET bit resets the USBTLL module. The bit value of 0x1 remains until the reset completes. When the software reset completes, the SOFTRESET bit is automatically set to 0x0 and has the same effect as the hardware reset.

#### 23.11.4.2.2 USBTLL Power Management

The USB protocol defines power-saving modes, where clocks can be shut down.

##### 23.11.4.2.2.1 IDLE Handshake Protocol

The PRCM module handles an IDLE handshake protocol for the USBTLL module. The IDLE handshake protocol lets the PRCM module require the HS USBTLL module to enter idle mode.

The way in which the HS USBTLL module acknowledges the PRCM IDLE request is configurable through the [USBTLL\\_SYSCONFIG\[4:3\] SIDLEMODE](#) bit field. [Table 23-942](#) lists related acknowledgment modes.

**Table 23-942. HS USBTLL Module SIDLEMODE Settings**

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The HS USB host controller acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations.
0x1	No-idle	The HS USB host controller never acknowledges any IDLE request from the PRCM module.
0x2	Smart-idle	The HS USB host controller acknowledges the IDLE request, basing its decision on its internal activity.

### 23.11.4.2.3 USBTLL Save and Restore

The SAR mechanism extracts the hardware context of the USBTLL module (after all USB activity is suspended) before switching off (saving), save it to an external always-on memory, and reinjects it later after the module is switched on again and reset (restored) seamlessly for the USB.

Hardware context of the USBTLL module is accessed through the `USBTLL_SAR_CNTX_i[31:0]` CNTX bit field.

The PRCM module enables the SAR mechanism for the USBTLL module. When set, the PRM module initiates the save and/or the restore sequences at the appropriate time. When not set, the USB host is treated as a standard module, and the save/restore sequences do not occur.

For more information, see [Section 3.9.3](#).

[Table 23-943](#) lists the USBTLL registers affected by the SAR context.

---

**NOTE:** Because all addresses give access to the same physical register (that is, to the same piece of context), the ULPI registers with multiple accesses (write, set, clear) are listed only once in the table.

---

**Table 23-943. USBTLL Registers Affected by the SAR Context**

### 23.11.4.2.4 USBTLL Channels and Ports

Following the same convention as UTMI and ULPI, the current specification is consistently PHY-centric (that is, directions are always given with respect to the transceiver emulated here by the TLL, and not with respect to the link controller): An input goes from the link controller to the TLL (transceiver emulator) (that is, it is an input for the USBTLL module). Reciprocally, an output goes from TLL (transceiver) to the link controller (that is, it is an output for the USBTLL module).

By convention, the local link controller is the controller integrated on the same IC as the USBTLL module: This is the HS USB host controller in the device. The remote link controller is the other controller, located off-chip (that is, on another IC). One controller is always the USB host, the other is the USB peripheral, and they communicate through the USBTLL module.

A channel is defined as a independent USB path through the USBTLL module, which always converts the UTMI+ transceiver interface protocol coming from the local link controller (the HS USB host controller in the device). There are two channels of the USBTLL module in the device.

A USB port is a set of I/O signals that carry the data and control information from/to a USB line. Several port formats exist, with different capabilities. A channel has three ports. If the channel is active, two ports are active at a time, depending on the channel configuration. The mode remains static throughout the USB operation.

#### 23.11.4.2.5 USBTLL Channel Configuration

A channel configuration is a set of software settings that specifies the connection of two of the channel ports through the USBTLL module. USB data and control injected on one side (or port) comes out on the other side (or port) after a certain amount of processing, depending on the mode. [Table 23-944](#), lists the modes.

All configurations connect the PHY UTMI port (attached to the HS USB host controller) to one of the other two ports (attached to a variety of transceivers or controllers on the pad side).

[Table 23-944](#) describes the available modes and the software settings required for each. Channel *i* has the following settings:

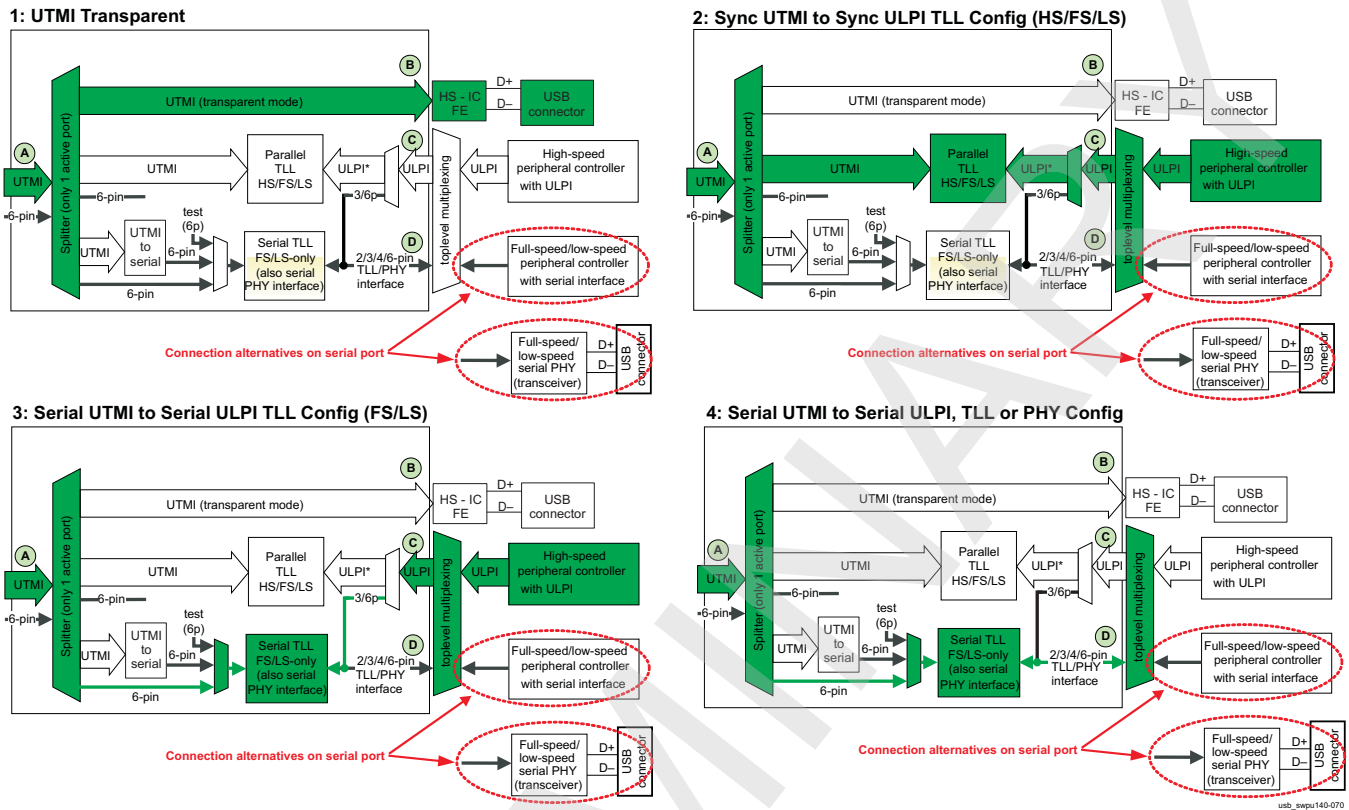

- CHANMODE: [TLL\\_CHANNEL\\_CONF\\_i\[2:1\]](#) CHANMODE bit field
- FLSMODE: [TLL\\_CHANNEL\\_CONF\\_i\[27:24\]](#) FLSMODE bit field
- FLSSEIRIALMODE\_3PIN/6PIN: Either the ULPI PHY-side [INTERFACE\\_CTRL\\_i\[1\]](#) FLSSEIRIALMODE\_3PIN bit or the [INTERFACE\\_CTRL\\_i\[0\]](#) FLSSEIRIALMODE\_6PIN bit (only one at a time can be set to 1)

**Table 23-944. USBTLL Channel Configuration**

Configuration	Mode	CHANMODE	FLSMODE	Other Settings	Ports	Speed	Remote Port Connection
1	UTMI transparent	0	N/A	-	A-B	-	UTMI transparent
2	ULPI synchronous TLL	0	N/A	FLSSEIRIALMODE_3PIN/6PIN = 0	A-C	HFL	ULPI link (peripheral controller)
3	Serial UTMI to serial ULPI TLL	0	N/A	FLSSEIRIALMODE_3PIN/6PIN = 1	A-C	FL	ULPI link (peripheral controller) supporting 3-/6-pin mode
4	Serial UTMI to serial TLL	1	0x4-0x7; 0xA-0xB	-	A-D	FL	Serial link (2-/3-/4-/6-pin)
4	Serial UTMI to serial PHY	1	0x0-0x3	-	A-D	FL	Serial transceiver (2-/3-/4-/6-pin)

Figure 23-256. Per-Configuration Data Path Through USBTLL

23.11.4.2.6 USBTLL VBUS Management and Emulations

In transceiver configurations, a USB cable is present, including a 5-V VBUS supply line. On the other hand, in TLL configurations, the physical USB lines are emulated and have no physical existence. This is especially true for the VBUS line, which distributes the 5-V power provided by the default host (or A-device) to the entire bus. VBUS is also used for signaling purposes, and those features must be emulated:

- A peripheral detects the presence of a host by detecting the presence of VBUS.
- USB OTG defines an elaborate voltage-sensing scheme to dynamically switch on and off VBUS (start and stop sessions). In the context of TLL, this brings no power savings compared to a simple suspend.
- In particular, USB OTG uses VBUS as a wake-up source (VBUS-pulsing SRP) for the default peripheral (or B-device).

For more information on how sideband controls are integrated, see Figure 23-241 and Figure 23-242 and the related explanations.

23.11.4.2.6.1 VBUS Control and Status for Transceiver (Non-TLL) Configurations

In non-TLL modes, VBUS exists, and the problem is to propagate control and status to and from the VBUS manager IC (typically, the transceiver).

Only serial transceiver configurations are concerned in the case of the HS USB host subsystem in the device.

23.11.4.2.6.1.1 VBUS Management in Serial Transceiver Configurations

VBUS management is not standardized in transceiver configurations. The chosen implementation is described in the following list (also see Figure 23-241).

- VBUS control required for host and OTG operation (VBUS drive, VBUS pullup "charge," VBUS pulldown "discharge") is assumed to be handled separately from the USBTLL module (that is, by software and straight to the power IC, which can be the transceiver, especially in OTG cases).
- VBUS status must be sampled by the appropriate hardware (again, most often the transceiver) and reported by software to the USBTLL module, using the [TLL\\_CHANNEL\\_CONF\\_i\[16\]](#) DRVVBUS and [TLL\\_CHANNEL\\_CONF\\_i \[15\]](#) CHRGVBUS bits, as indicated in [Table 23-945](#).

[Table 23-945](#) lists the values to write to the [TLL\\_CHANNEL\\_CONF\\_i](#) register depending on the VBUS status observed by the transceiver on the VBUS line. The same register fields are also used in TLL configuration, and have been named according to that second configuration. In transceiver configurations the actual signification of the fields is:

- DRVVBUS: Set to 1 to report a VBUS level greater than VBUS valid.
- CHRGVBUS: Set to 1 to report a VBUS level greater than session valid.

**Table 23-945. VBUS Level Software Reporting for Serial Transceiver Configuration**

VBUS Status	<a href="#">TLL_CHANNEL_CONF_i[16]</a> DRVVBUS	<a href="#">TLL_CHANNEL_CONF_i[15]</a> CHRGVBUS
VBUS valid	1	1
Session valid (A/B)	0	1
Session not valid	0	0
Session end	0	0

#### 23.11.4.2.6.2 VBUS Emulation for TLL Configurations

The TLL VBUS emulation sums up all actions on the VBUS line and obtains a voltage level, which is reported in the VBUS status bits following the protocol. The level depends on the immediate VBUS actions and has no memory of previous levels, whereas an actual VBUS line behaves like an RC circuit and takes time to charge and discharge. This causes the following differences:

- The TLL level always jumps abruptly from session valid to session end (and back) with no transient time in between (where session is neither valid nor ended) as in real life.
- The charge feature is used for VBUS-pulsing SRP and is enabled long enough to go over the session valid threshold, but without reaching VBUS valid. In the TLL, the transition to session valid is immediate, and VBUS valid is never reached even if the charge is intentionally kept active.
- The discharge feature is used in real life to accelerate the voltage drop of an undriven VBUS toward the session-end level. For TLL, therefore, this is useless (although the UTMI input/ULPI register bit does exist, for compatibility), and is always don't care.

#### 23.11.4.2.6.2.1 VBUS Emulation in ULPI TLL Modes

[Table 23-946](#) summarizes the VBUS emulation in ULPI TLL modes. VBUS controls are writable, static PHY-side registers on the ULPI side, and input signals on the ULPI ports (port A). VBUS status bits are read-only, volatile PHY-side registers on the ULPI, and output signals on the ULPI ports (port A).

**Table 23-946. Emulation of VBUS Levels for UTMI-to-ULPI TLL Mode**

VBUS Controls (Actions)			VBUS Level	VBUS Status		
<a href="#">OTG_CTRL_i[5]</a> DRVVBUS	<a href="#">OTG_CTRL_i[4]</a> CHRGVBUS	<a href="#">OTG_CTRL_i[3]</a> DISCHRGVBUS		<a href="#">USB_INT_STATU TUS_i[1]</a> VBUSVALID bit	<a href="#">USB_INT_STATU S_i[2]</a> SESSVALID bit	<a href="#">USB_INT_STATU S_i[3]</a> SESSSEND bit
1	X	X	VBUS valid	1	1	0
0	1	X	VBUS valid	0	1	0
0	0	X	Session end	0	0	1

### **23.11.4.2.6.2 VBUS Emulation in Serial TLL Modes**

In serial TLL modes, VBUS status and control is implemented with ad hoc sideband signals (see [Figure 23-242](#)).

VBUS control can be done in software, by writing to the following fields of the [TLL\\_CHANNEL\\_CONF\\_i](#) register:

- **DRVVBUS:** Set to 1 to drive VBUS to 5 V (for A-device or host)
- **CHRGVBUS:** Set to 1 to pull up VBUS (for SRP)
- There is no pulldown (discharge) control, because the emulated VBUS has no latency and VBUS level goes to the session-end level as soon as it is neither driven nor pulled up.

Alternatively, VBUS drive can also be hardware-controlled through a dedicated input. (The DRVVBUS bit and input signal are ORed internally.)

VBUS status is available on dedicated output signals. If those outputs are not available at the top level, a software alternative is to use the voltage status reported on the interface (through the standard UTMI+ sideband signals) of the local controller (the HS USB host controller in the device) and to pass it to the remote controller (a peripheral controller) by means of an ad hoc software-controller interface other than the USB. This is based on the fact that the level of VBUS is the same on both extremities of the bus (that is, it does not matter which side does the measurement).

### **23.11.4.2.7 USBTLL Multimode Serial Port**

The multimode serial port requires six bidirectional I/O pads to support all eight defined modes (selected in the [TLL\\_CHANNEL\\_CONF\\_i\[27:24\]](#) FLSMODE bit field when field CHANMODE = 0x1 = UTMI-to-serial). Those modes are FS/LS only (that is, HS is not supported over a serial interface).

The pads are named TXEN, TXDAT, TXSE0, RXRCV, RXDP, and RXDM after their functionality in standard 6-pin mode (mode 0). Each pad has an input, output, and output-enable signal associated with it on the USBTLL entity.

[Table 23-947](#) lists the functionality of each pad in each mode. USBTLL outputs are shown in yellow, inputs in blue, and bidirectional pads in green.

**Table 23-947. Serial Mode Description, Signal Functionality**

Usual Name	6-Pin Mode	6-Pin Mode (Alt)	3-Pin Mode	4-Pin Mode	6-Pin TLL Mode	6-Pin TLL (Alt) Mode	3-Pin TLL Mode	4-Pin TLL Mode	2-Pin TLL Mode	2-Pin TLL (Alt) Mode
<a href="#">TLL_CHANNEL_CONF_i</a> [27:24] FLSMODE field	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7	0xA	0xB
TX encoding	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM
RX encoding	DP/DM/RCV	DP/DM/RCV	DAT/SE0	DP/DM/RCV	DP/DM/RCV	DP/DM/RCV	DAT/SE0	DP/DM/RCV	DAT/SE0	DP/DM
Pin use	Unidirectional	Unidirectional	Bidirectional	Bidirectional	Unidirectional	Unidirectional	Bidirectional	Bidirectional	Bidirectional	Bidirectional
Pin count	6	6	3	4	6 or 5 <sup>(1)</sup>	6 or 5 <sup>(1)</sup>	3	4 or 3 <sup>(2)</sup>	2	2
<b>I/O Pad Function Per Mode</b>										
TXEN	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	N/C	N/C
TXDAT	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX SE Plus Data	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX SE Plus Data
TXSE0	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX SE Minus Data	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX force SE0	TX/RX force SE0	TX/RX SE Minus Data
RXRCV	RX Diff Data	RX Diff Data	N/C	RX Diff Data	RX Diff Data	RX Diff Data	N/C	RX Diff Data	N/C	N/C
RXDP	RX SE Plus Data	RX SE Plus Data	N/C	N/C	RX SE Plus Data	RX SE Plus Data	N/C	N/C	N/C	N/C
RXDP	RX SE Minus Data	RX SE Minus Data	N/C	N/C	RX SE Minus Data	RX SE Minus Data	N/C	N/C	N/C	N/C

<sup>(1)</sup> RXRCV and RXDP carry the same information: RXDP can drive both inputs of the remote controller, and RXRCV can be kept unused.

<sup>(2)</sup> Same remark for TXDAT (for outputs) and RXRCV: TXDAT only is enough.

**23.11.4.2.8 USBTLL Attach/Connect Emulation for Serial Modes**

This section applies to all serial TLL modes in the following circumstances:

- In UTMI-to-serial mode (`TLL_CHANNEL_CONF_i[2:1] CHANMODE = 0x1`) for all TLL values of the `TLL_CHANNEL_CONF_i[27:24] FLSMODE` bit field (0x4-0x7; 0xA-0xB)
- In UTMI-to-ULPI TLL mode (`TLL_CHANNEL_CONF_i[2:1] CHANMODE = 0x0`) when the ULPI bus is switched to 6-pin or 3-pin serial modes

In those modes, the USB bus lines are emulated by USBTLL internal logic and are never available on the outside. The pullup/pulldown actions described in the USB specification cannot be applied directly, and the USB cable cannot be physically attached.

Because serial modes do not specify a standard format for those sideband settings, a custom software-controlled one is implemented:

- The `TLL_CHANNEL_CONF_i[4]` TLLATTACH bit emulates the physical attachment of the two controllers through a TLL cable.
  - When this bit is cleared, the local controller RX path shows only the local controller (the HS USB host controller) actions on the bus: TX driving, pullups, pulldowns. The same thing applies for the remote controller RX path (except that test override is not available).
  - When the bit is set, the actions of both sides are applied to the same bus and are resolved, similar to a real bus. The RX path for both sides shows the same bus state.
- The `TLL_CHANNEL_CONF_i[5]` TLLCONNECT bit emulates the USB electrical connect (that is, the pullup by the USB peripheral of one of the two USB lines [by a 1.5 Kohm resistor]), which causes the line state to transition from SE0 to J, which is detected by the USB host. The register bit is ORed with a USBTLL module input signal; the connect control can be software (L4\_CFG interconnect write access) or hardware (input level). The speed of the connection is determined by the TLLFULLSPEED bit.
- The `TLL_CHANNEL_CONF_i[6]` TLLFULLSPEED bit determines the speed (full or low) of the USB connect to be emulated. The connect enable (controlled as previously defined) results in the pulling up of D+ (1 = full speed) or D- (0 = low speed) (see [Table 23-948](#)).
- The 15 Kohm pulldowns are implicit: Because they are supposed to be turned on at least on the host side of the bus, they do not require additional control.

**NOTE:** Sideband control and status actions such as pullups are included in parallel (that is, nonserial) standards (UTMI, ULPI), and do not require custom additions.

**Table 23-948. Pullup Enable Emulation in Serial TLL Modes**

TLL_CHANNEL_CONF_i Fields		Input Signal	Resulting TLL Pullup Emulation	
TLLFULLSPEED	TLLCONNECT	USB State	D+ Pullup	D- Pullup
1	0	Full-speed unconnected	Off	Off
1	1	Full-speed connected	On	Off
0	0	Low-speed unconnected	Off	Off
0	1	Low-speed connected	Off	On

### 23.11.5 HS Multiport USB Host Subsystem Low-Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the HS USB host subsystem.

#### 23.11.5.1 Global Initialization

##### 23.11.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the HS USB host subsystem is used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the HS USB host subsystem.

Table 23-949 describes the global initialization of surrounding modules.

**Table 23-949. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	All clocks must be enabled. See <a href="#">Section 3.6.3.2, CM Clock Source</a> .
Cortex-A9 MPU INTC or Cortex-M3 MPU INTC	The Cortex-A9 MPU or Cortex-M3 MPU INTC must be configured to enable the interrupt request generation to the Cortex-A9 MPU or Cortex-M3 MPU subsystem when interrupt requests are generated by the HS multiport USB host subsystem. See the respective functional description in <a href="#">Chapter 17 Interrupt Controller</a> for the MPUs.
Interconnect (L3 and L4)	For more information, see <a href="#">Section 13.2, L3 Interconnect</a> , and <a href="#">Section 13.3, L4 Interconnect</a> .

##### 23.11.5.1.2 HS Multiport USB Host Subsystem Global Initialization

This procedure in [Table 23-950](#) initializes the HS multiport USB host subsystem after a power-on or software reset.

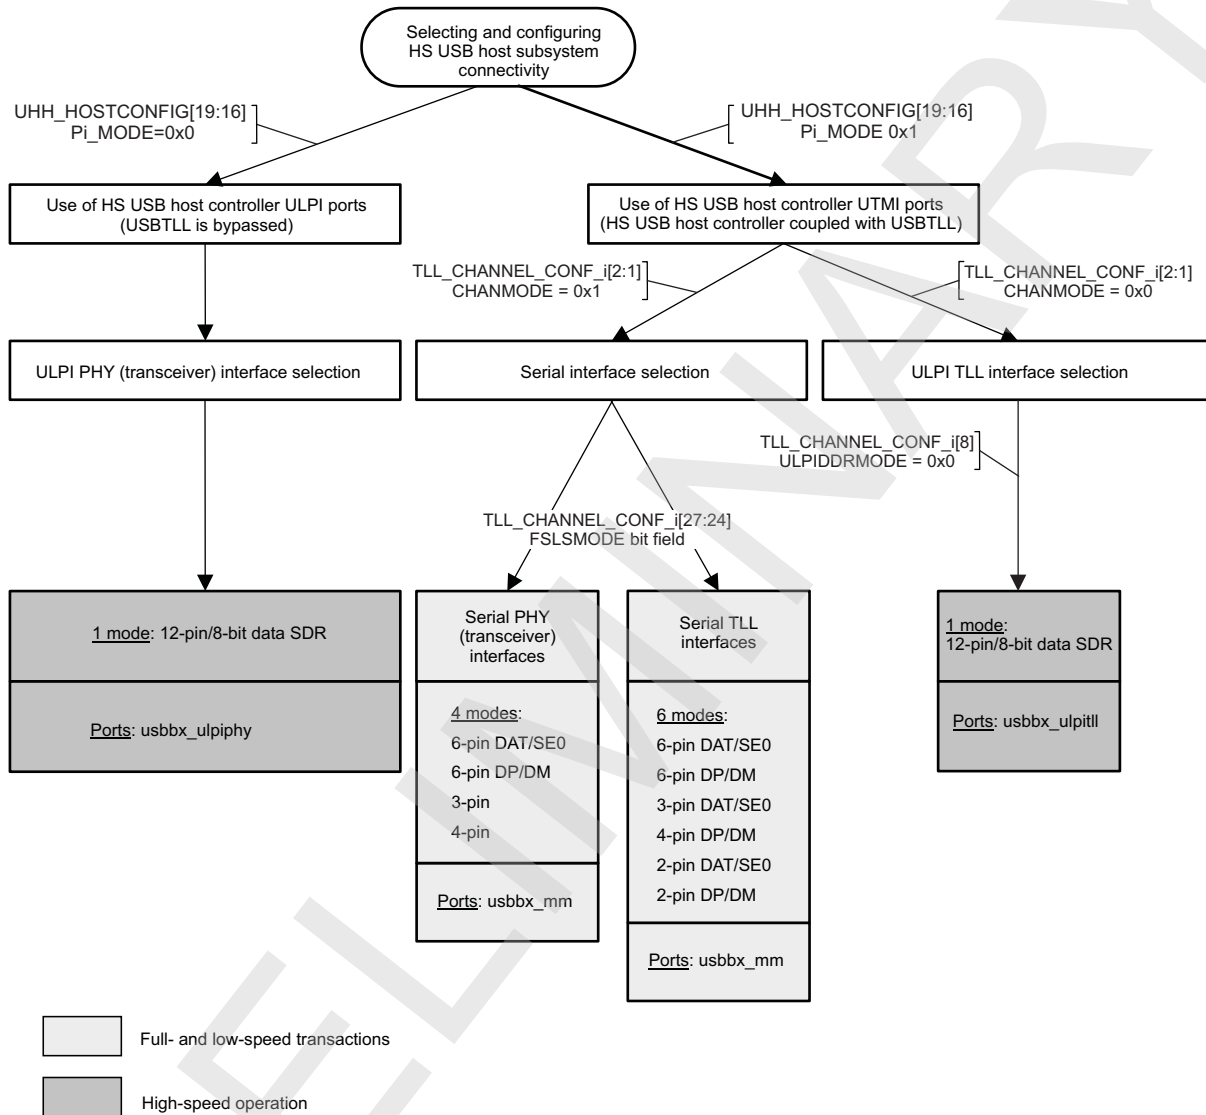

**Table 23-950. HS Multiport USB Host Subsystem Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Perform a software reset on the TLL module.	<a href="#">USBTLL_SYSCONFIG</a> [1] SOFTRESET	0x1
Wait until reset is finished.	<a href="#">USBTLL_SYSSTATUS</a> [0] RESETDONE	=0x1
Enable IRQ event for the TLL module.	<a href="#">USBTLL_IRQENABLE</a> [1] FCLK_END_EN	0x1
Enable IRQ event for the TLL module.	<a href="#">USBTLL_IRQENABLE</a> [0] FCLK_START_EN	=0x1
Perform a software reset on the HS USB controller.	<a href="#">UHH_SYSCONFIG</a> [0] SOFTRESET	0x1
Wait until the EHCI HS host is out of reset.	<a href="#">UHH_SYSSTATUS</a> [2] EHCI_RESETDONE	=0x0
Wait until the OHCI HS host is out of reset.	<a href="#">UHH_SYSSTATUS</a> [1] OHCI_RESETDONE	=0x0
Enable IRQ event for the OHCI HS host.	<a href="#">HCINTERRUPTENABLE</a> [31] MIE	0x1
Enable IRQ event for the EHCI HS host.	<a href="#">USBINTR</a> [0] USBIE	0x1

**23.11.5.2 Operational Modes Configuration (Selecting and Configuring USB Connectivity)**

Figure 23-257 shows how to select and configure the HS USB host subsystem connectivity.

**Figure 23-257. Selecting and Configuring HS USB Host Subsystem Connectivity**

usb\_swpu140-034

**Table 23-951. Register Call Summary for Selecting and Configuring High-Speed USB Host Subsystem Connectivity**

Register Name	
UHH_HOSTCONFIG	TLL_CHANNEL_CONF_i

**23.11.5.3 USBTLL Registers**

The USBTLL module contains two types of software-programmable registers.

**23.11.5.3.1 TLL Control and Status Registers**

These 32-bit registers configure the various channels. These registers are accessed by the MPU through the L4\_CFG interconnect. They are used primarily before USB activity starts. The registers are:

- OCP-standard registers for revision number, IRQ, clocking management, etc.

- TLL-specific registers

### 23.11.5.3.2 ULPI PHY-Side Registers

Each TLL channel emulates a ULPI transceiver and therefore contains this set of 8-bit PHY-side registers, per ULPI specification. The registers are:

- All ULPI-mandatory standard registers and fields
- A selection of ULPI-optional standard registers and fields, when relevant to the TLL context
- Vendor-specific registers, mapped at the addresses specified for that purpose in the ULPI specification

These registers are accessed by the external (that is, off-chip) link controller over the ULPI port of each channel, in the 0x100-byte ULPI address space, using the ULPI register access protocol.

They are accessible by the L4\_CFG interconnect: The ULPI register sets of all channels are mapped side by side in the upper part of the L4\_CFG interconnect address space, where they can be accessed through byte accesses. If a conflict occurs between the two access modes, access over ULPI has priority, but both accesses eventually complete correctly. For normal USB activity, all register accesses are expected to go over ULPI, and register changes caused by L4\_CFG interconnect accesses can compromise proper USB operation. The L4\_CFG interconnect access port is intended for:

- Miscellaneous test and debug
- Nonintrusive observation of ongoing USB operations (test)
- Context restore: During USB suspend periods, the USBTLL module can be switched off to save power. When the module is switched on again, the ULPI register contents, which have been lost, can be restored over the L4\_CFG interconnect before USB operations restart, provided they were saved elsewhere beforehand.

### 23.11.6 HS USB Host Subsystem Register Manual

This section provides the register description of the module.

#### 23.11.6.1 USB\_Host\_HS Instance Summary

Table 23-952 summarizes the USB\_Host\_HS instance.

Table 23-952. USB\_Host\_HS Instance Summary

Module Name	L4_CFG Base Address	Size
USBTLLHS_config	0x4A06 2000	2KB
USBTLLHS_ULPI	0x4A06 2800	2KB
HSUSBHOST	0x4A06 4000	2KB
OHCI	0x4A06 4800	1KB
EHCI	0x4A06 4C00	1KB

#### 23.11.6.2 USBTLLHS\_config Registers

##### 23.11.6.2.1 USBTLLHS\_config Register Summary

Table 23-953 summarizes the USBTLLHS\_config register mapping.

Table 23-953. USBTLLHS\_config Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
USBTLL_REVISION	R	32	0x0000 0000	0x4A06 2000
USBTLL_HWINFO	R	32	0x0000 0004	0x4A06 2004
USBTLL_SYSCONFIG	RW	32	0x0000 0010	0x4A06 2010
USBTLL_SYSSTATUS	R	32	0x0000 0014	0x4A06 2014
USBTLL_IRQSTATUS	RW	32	0x0000 0018	0x4A06 2018
USBTLL_IRQENABLE	RW	32	0x0000 001C	0x4A06 201C

TLL_CHANNEL_CONF_j <sup>(1)</sup>	RW	32	0x0000 0040 + (0x4 * i)	0x4A06 2040 + (0x4 * i)
USBTLL_SAR_CNTX_j <sup>(2)</sup>	RW	32	0x0000 0400 + (0x4 * j)	0x4A06 2400 + (0x4 * j)

<sup>(1)</sup> i = 0 to 2

<sup>(2)</sup> j = 0 to 6

#### CAUTION

The USBTLLHS\_config registers are limited to 32-bit data accesses; 16-bit and 8-bit accesses are not allowed and can corrupt register content.

##### 23.11.6.2.2 USBTLLHS\_config Register Description

through describe the USBTLLHS\_config registers.

18	TESTTXEN	<p>Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode)</p> <p>0x0: Drive Tx according to TestTxDat/Se0 0x1: Drive Tx Hiz (no drive: pullups determine line state)</p>	RW	0
17	TESTEN	<p>Enable manual test override for serial mode Tx path (from local controller's UTMI port)</p> <p>0x0: No override. Tx is from local link controller 0x1: Override enabled</p>	RW	0
16	DRVVBUS	<p>VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS drive * In PHY config, write 1 to report "VBUS valid" status (of actual VBUS) to UTMI controller</p> <p>0x0: VBUS not driven 0x1: VBUS driven to 5V</p>	RW	0
15	CHRGVBUS	<p>VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS charge/pullup (OTG) * In PHY config, write 1 to reports "session valid" status (of actual VBUS) to UTMI controller</p> <p>0x0: VBUS not charged, session not valid 0x1: VBUS charged, session valid</p>	RW	0
14:12	RESERVED		R	0x0
11	ULPINOBITSTUFF	<p>Disable bitstuff emulation in ULPI TLL for ULPI ChanMode</p> <p>0x0: Bitstuff enabled, following USB standard 0x1: No bitstuff or associated delays (nonstandard)</p>	RW	0

Bits	Field Name	Description	Type	Reset
10	ULPIAUTOIDLE	For ChanMode = ULPI TLL only. Allow the ULPI output clock to be stopped when ULPI goes into asynchronous mode (low-power, 3-pin serial, 6-pin serial). No effect in ULPI input clock mode.  0x0: ULPI output clock always-on 0x1: ULPI output clock stops during asynchronous ULPI modes	RW	1
9	UTMIAUTOIDLE	For ChanMode = ULPI TLL only. Allow the UTMI clock (output) to be stopped when UTMI goes to suspended mode (suspendm = 0)  0x0: UTMI clock output always on 0x1: UTMI clock output gated upon suspend	RW	1
8	RESERVED		R	0
7	ULPIOUTCLKMODE	ULPI clocking mode select for ULPI TLL ChanMode. Hardcoded, for legacy only.  Read 0x1: ULPI clock provided by PHY side (i.e. TLL, from functional clock). ULPI clock is output	R Rreturns 1s	1
6	TLLFULLSPEED	Sets PHY speed emulation in TLL (full/slow), which determines the line to pull up upon connect. The two connect source controls are: input m(N)_tlpuen, register field TIIConnect.  0x0: Connect is Low-speed: D- pullup 0x1: Connect is Full-Speed: D+ pullup	RW	1
5	TLLCONNECT	Emulation of Full/Low-Speed connect (i.e. D+ resp D-pullup) for serial TLL modes. Speed is determined by field TIIISpeed.  0x0: Unconnected 0x1: Connected	RW	0
4	TLLATTACH	Emulates cable attach/detach for all serial TLL modes: * ChanMode = serial, in TLL mode (FsLsMode) * ChanMode = ULPI, in serial mode (6pin/3pin TLL)  0x0: cable detach emulated on serial TLL 0x1: cable attach emulated on serial TLL	RW	1
3	UTMIISADEV	Select the cable end "seen" by UTMI side of TLL, i.e. the emulated USB cable's orientation. Note that host must always be on A side, Peripheral on B side. Reset value depends on generic DEFUTMIISHOST.  0x0: UTMI side is peripheral, ULPI side is host 0x1: UTMI side is host, ULPI side is peripheral	RW	1
2:1	CHANMODE	Main channel mode selection  0x0: UTMI-to-ULPI TLL mode (HS capable): to ULPI controller 0x1: UTMI-to-serial (FS/LS) mode: to serial controller (TLL) or serial PHY 0x2: Transparent UTMI mode: to UTMI PHY 0x3: No mode selected	RW	0x0
0	CHANEN	Active-high channel enable. A disabled channel is unlocked and kept under reset.  0x0: Channel #N disabled 0x1: Channel #N enabled	RW	0

<b>Physical Address</b>	See <a href="#">Table 23-972</a> .	<b>Instance</b>	USBLLHS_ULPI
<b>Description</b>	Part of nonstandard UTMI-to-ULPI mailbox system, implemented if HDL generic VCS_MAILBOX bit is 1. UTMI-standard Vcontrol vector byte is sent by the UTMI controller (other side of TLL) to its PHY (emulated here by the TLL). Alternatively, data can be also written directly into the register. Can contain any user-defined data. Vcontrol bit changes can be used to assert the ULPI ALT interrupt. Lowest VCS_CTRL_WIDTH (HDL generic) bits are implemented, others are always-0, read-only. (UTMI standard is 4-bit).

<b>Physical Address</b>	See <a href="#">Table 23-1053</a> .		
<b>Description</b>	Static configuration of the USB HS host		
<b>Type</b>	RW		

Bits	Field Name	Description	Type	Reset
31	APP_START_CLK	When the OHCI clocks are suspended, the system has to assert this signal to start the clocks (12 and 48 MHz). This must be deasserted after the clocks are started and before the host is suspended again. (Host is suspended means HCFS = SUSPEND or all the OHCI ports are suspended.)	RW	0
30:20	RESERVED		R	0X000
19:18	P2_MODE	Port 2 interface configuration. Each bit corresponds to an internal "strap" signal, and output: Bit 0 = ulpi_bypass Bit 1 = hsic_en  0x0: To external ULPI PHY, HS only 0x1: To UTMI PHY (or ULPI TLL), FS/LS capable 0x2: Forbidden 0x3: To HSIC digital front-end (DFE), HS only	RW	0x0

Bits	Field Name	Description	Type	Reset
17:16	P1_MODE	Port 1 interface configuration. Each bit corresponds to an internal "strap" signal, and output: Bit 0 = ulpi_bypass Bit 1 = hsic_en  0x0: To external ULPI PHY, HS only 0x1: To UTMI PHY (or ULPI TLL), FS/LS capable 0x2: Forbidden 0x3: To HSIC digital front-end (DFE), HS only	RW	0x0
15:10	RESERVED		R	0x00
9	P2_CONNECT_STATUS	Connection status for port 2 Note that reset value does not correspond, on purpose, to the default connection status.  Read 0x0: Disconnected Read 0x1: Peripheral connected and active on port	R	1
8	P1_CONNECT_STATUS	Connection status for port 1 Note that reset value does not correspond, on purpose, to the default connection status.  Read 0x0: Disconnected Read 0x1: Peripheral connected and active on port	R	1
7:6	RESERVED		R	0x0
5	ENA_INCR_ALIGN	Force alignment of bursts to the respective burst-size boundaries <sup>(1)</sup>  0x0: Disable burst type 0x1: Enable burst type	RW	0
4	ENA_INCR16	Control the use of INCR16-type bursts (in AHB sense)  0x0: Disable burst type 0x1: Enable burst type	RW	1
3	ENA_INCR8	Control the use of INCR8-type bursts (in AHB sense)  0x0: Disable burst type 0x1: Enable burst type	RW	1
2	ENA_INCR4	Control the use of INCR4-type bursts (in AHB sense)  0x0: Disable burst type 0x1: Enable burst type	RW	1
1	AUTOPPD_ON_OVERCUR_EN	Configure reaction upon port overcurrent condition. This function is not supported at the device level.  0x0: Port remains on upon overcurrent. 0x1: Port is powered down automatically upon overcurrent.	RW	0X0
0	RESERVED		R	0

<sup>(1)</sup> This bit must be set to 1 to avoid buffer underflow.

**CAUTION**

The high-speed USB registers are limited to 32-bit data accesses; 16-bit and 8-bit accesses are not allowed and can corrupt register content.

OHCI register descriptions conform to the OHCI USB standard: Open Host Controller Interface Specification for USB, Release 1.0a. For more information about these registers or for new specification releases, search OHCI on [www.usb.org](http://www.usb.org).

**23.11.6.5.2 OHCI Register Description**

through describe the OHCI registers.

Bits	Field Name	Description	Type	Reset
31:21	RESERVED	Reserved	R	0x000
20	PRSC	Port 1 reset status change. This bit is set when the Port 1 port reset status bit has changed. Write 0x0: No effect Write 0x1: Clears this bit	RW	0
19	RESERVED		R	0
18	PSSC	Port 1 suspendsstatus change. Set when the port leaves the suspend state, i.e. after the full resume sequence has completed. Write 0x0: No effect Read 0x0: No resume completed (since either the last SW clear, or the last port reset) Read 0x1: Resume completed on the port Write 0x1: Clears the bit	RW	0
17	PESC	Port 1 enable status change. This bit is set when the Port 1 port enable status has changed. Write 0x0: No effect Write 0x1: Clears this bit	RW	0

Bits	Field Name	Description	Type	Reset
16	CSC	Port 1 connect status change. This bit is set when the Port1 port current connect status has changed due to a connect or disconnect event. If current connect status is 0 when a set port reset, set port enable, or set port suspend write occurs, this bit is set. Write 0x0: No effect Write 0x1: Clears this bit Note: If the DR bit <a href="#">HCRHDESCRIPTORB[1]</a> is set, this bit is set only after a root hub reset to inform the system that the device is attached.	RW	0
15:10	RESERVED	Reserved	R	0x00
9	LSDA_CPP	Port 1 low-speed device attached/clear port power. This bit is valid only when port 1 current connect status is 1. Read 0x0: A full-speed device is attached to port 1. Read 0x1: A low-speed device is attached to port 1. Write 0x0: No effect Write 0x1: Clears the port 1 port power status	RW	0
8	PPS_SPP	Port 1 port power status/set port power. Read 0x0: Port 1 power is enabled. Read 0x1: Port 1 power is not enabled. Write 0x0: No effect Write 0x1: Sets the port 1 port power status bit	RW	0
7:5	RESERVED	Reserved	R	0x0
4	PRS_SPR	Port 1 port reset status/set port reset. Read 0x0: USB reset is not being sent to port 1. Read 0x1: Port 1 is signaling the USB reset. Write 0x0: No effect Write 0x1: Sets the port 1 port reset status bit and causes the USB host controller to begin signaling USB reset to port 1	RW	0
3	RESERVED		R	0
2	PSS_SPS	Port 1 port suspend status/set port suspend. This bit is cleared automatically at the end of the USB resume sequence and also at the end of the USB reset sequence. Write 0x0: No effect Read 0x0: Port 1 is not in the USB suspend state. Read 0x1: Port 1 is in the USB suspend state or is in the resume sequence. Write 0x1: If port 1 current connect status is 1, sets the port 1 port suspend status bit and places port 1 in USB suspend state. If current connect status is 0, sets instead connect status change to inform the USB host controller driver of an attempt to suspend a disconnected port.	RW	0
1	PES_SPE	Port 1 port enable status/set port enable. This bit is automatically set at completion of port 1 USB reset if it was not already set before the USB reset completed, and is automatically set at the end of a USB suspend if the port was not enabled when the USB resume completed. Read 0x0: Port 1 is not enabled. Read 0x1: Port 1 is enabled. Write 0x0: No effect Write 0x1: When port 1 current connect status is 1 sets the port 1 port enable status bit. When port 1 current status is 0 has no effect.	RW	0
0	CCS_CPE	Port 1 current connection status/clear port enable. Read 0x0: No USB device is attached to port 1. Read 0x1: Port 1 currently has a USB device attached. Write 0x0: No effect Write 0x1: Clears the port 1 port enable bit Note: This bit is set to 1 if the DR bit <a href="#">HCRHDESCRIPTORB[1]</a> is set to indicate a nonremovable device on port 1.	RW	0

18	PSSC	Port 2 suspend status change. Set when the port leaves the suspend state, i.e. after the full resume sequence has completed. Write 0x0: No effect Read 0x0: No resume completed (since either the last SW clear, or the last port reset) Read 0x1: Resume completed on the port Write 0x1: Clears the bit	RW	0
17	PESC	Port 2 enable status change. This bit is set when the Port 2 port enable status has changed. Write 0x0: No effect Write 0x1: Clears this bit	RW	0
16	CSC	Port 2 connect status change. This bit is set when the Port 2 port current connect status has changed due to a connect or disconnect event. If current connect status is 0 when a set port reset, set port enable, or set port suspend write occurs, this bit is set. Write 0x0: No effect Write 0x1: Clears this bit Note: If the DR bit <a href="#">HCRHDESCRIPTORB[1]</a> is set, this bit is set only after a root hub reset to inform the system that the device is attached.	RW	0
15:10	RESERVED	Reserved	R	0x00
9	LSDA_CPP	Port 2 low-speed device attached/clear port power. This bit is valid only when port 2 current connect status is 1. Read 0x0: A full-speed device is attached to port 2. Read 0x1: A low-speed device is attached to port 2. Write 0x0: No effect Write 0x1: Clears the port 2 port power status	RW	0

Bits	Field Name	Description	Type	Reset
8	PPS_SPP	Port 2 port power status/set port power. Read 0x0: Port 2 power is enabled. Read 0x1: Port 2 power is not enabled. Write 0x0: No effect Write 0x1: Sets the port 2 port power status bit	RW	0
7:5	RESERVED	Reserved	R	0x0
4	PRS_SPR	Port 2 port reset status/set port reset. Read 0x0: USB reset is not being sent to port 2. Read 0x1: Port 2 is signaling the USB reset. Write 0x0: No effect Write 0x1: Sets the port 2 port reset status bit and causes the USB host controller to begin signaling USB reset to port 2	RW	0
3	RESERVED		RW	0
2	PSS_SPS	Port 2 port suspend status/set port suspend. This bit is cleared automatically at the end of the USB resume sequence and also at the end of the USB reset sequence. Write 0x0: No effect Read 0x0: Port 2 is not in the USB suspend state. Read 0x1: Port 2 is in the USB suspend state or is in the resume sequence. Write 0x1: If port 2 current connect status is 1, sets the port 2 port suspend status bit and places port 2 in USB suspend state. If current connect status is 0, sets instead connect status change to inform the USB host controller driver of an attempt to suspend a disconnected port.	RW	0
1	PES_SPE	Port 2 port enable status/set port enable. This bit is automatically set at completion of port 2 USB reset if it was not already set before the USB reset completed, and is automatically set at the end of a USB suspend if the port was not enabled when the USB resume completed. Read 0x0: Port 2 is not enabled. Read 0x1: Port 2 is enabled. Write 0x0: No effect Write 0x1: When port 2 current connect status is 1 sets the port 2 port enable status bit. When port 2 current status is 0 has no effect.	RW	0
0	CCS_CPE	Port 2 current connection status/clear port enable. Read 0x0: No USB device is attached to port 2. Read 0x1: Port 2 currently has a USB device attached. Write 0x0: No effect Write 0x1: Clears the port 2 port enable bit Note: This bit is set to 1 if the DR bit <a href="#">HCRHDESCRIPTORB[1]</a> is set to indicate a nonremovable device on port 2.	RW	0

<sup>(1)</sup> i = 0 to 2**CAUTION**

The high-speed USB registers are limited to 32-bit data accesses; 16-bit and 8-bit accesses are not allowed and can corrupt register content.

EHCI register descriptions conform to the EHCI USB standard: Enhanced Host controller Interface (EHCI) specification for USB, Release 1.0. For more information about these registers or for new specification releases, search EHCI on [www.usb.org](http://www.usb.org).

**23.11.6.6.2 EHCI Register Description**

through describe the EHCI registers.

**Table 23-1116. HCCAPBASE**

**Table 23-1118. HCSPARAMS**

<b>Address Offset</b>	0x0000 0004	<b>Instance</b>	EHCI
<b>Physical Address</b>	See <a href="#">Table 23-1115</a> .		
<b>Description</b>	Host Controller Structural Parameters		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								RESERVED		P_INDICATOR		N_CC				N_PCC				PRR	RESERVED		PPC	N_PORTS							

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	Reserved	R	0x000
19:17	RESERVED	Reserved	R	0x0
16	P_INDICATOR	Port indicator support indication  This bit indicates whether the ports support port indicator control.  0x1: The port status and control registers include a read/write field for controlling the state of the port indicator.	R	0
15:12	N_CC	Number of Companion Controllers  This field indicates the number of companion controllers associated with this USB 2.0 host controller.  0x0: There are no companion host controllers. Port-ownership hand-off is not supported. Only high-speed devices are supported on the host controller root ports.  Others: there are companion USB 1.1 host controller(s). Port-ownership hand-off is supported. High-, full-, and low-speed devices are supported on the host controller root ports.	R	0x1
11:8	N_PCC	Number of Ports per Companion Controller  This field indicates the number of ports supported per companion host controller. It is used to indicate the port routing configuration to system software.  For example, if N_PORTS has a value of 6 and N_CC has a value of 2, then N_PCC can have a value of 3.  The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc.  The number in this field must be consistent with N_PORTS and N_CC.	R	0x3
7	PRR	Port Routing Rules	R	0

Bits	Field Name	Description	Type	Reset
		The first N_PCC ports are routed to the lowest-numbered function companion host controller, the next N_PCC ports are routed to the next lowest-function companion controller, and so on.		
6:5	RESERVED	Reserved	R	0x0
4	PPC	Port Power control  This field indicates whether the host controller implementation includes port power control. 0x0: The ports do not have port power switches. 0x1: The ports have port power switches.	R	1
3:0	N_PORTS	Number of downstream ports  This field specifies the number of physical downstream ports implemented on this host controller.	R	0x3

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Reserved	R	0x0
27:24	HIRD	<p>Host-initiated resume duration.</p> <p>If LPM is enabled, this field is RW; otherwise, it is R.</p> <p>The minimum for K-state during resume from LPM:</p> <p>0x0: 50 μs</p> <p>Each increment adds 75 μs.</p>	RW	0x0
23:16	ITC	<p>Interrupt Threshold Control</p> <p>This field is used by the system software to select the maximum rate at which the host controller issues interrupts. The only valid values are defined below. If software writes an invalid value to this register, the results are undefined.</p> <p>0x00: Reserved</p> <p>0x01: 1 microframe</p> <p>0x02: 2 microframes</p> <p>0x04: 4 microframes</p>	RW	0x08

Bits	Field Name	Description	Type	Reset
		0x08: 8 microframes (default, equates to 1 ms) 0x10: 16 microframes (2 ms) 0x20: 32 microframes (4 ms) 0x40: 64 microframes (8 ms) Others: Undefined		
15:12	RESERVED	Reserved	R	0x0
11	ASPME	Asynchronous Schedule Park Mode Enable 0x0: Park mode is disabled. 0x1: Park mode is enabled.	RW	1
10	RESERVED	Reserved	R	0
9:8	ASPMC	Asynchronous Schedule Park Mode Count  It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the asynchronous schedule before continuing traversal of the asynchronous schedule.  Valid values are 0x1 to 0x3. The software must not write a 0 to this bit when Park Mode Enable is a 1 as this may result in undefined behavior.	RW	0x3
7	LHCR	Light Host Controller Reset  It allows the driver to reset the EHCI controller without affecting the state of the ports or the relationship to the companion host controllers.  Read 0x0: Light host controller reset is complete and it is safe for host software to reinitialize the host controller. Read 0x1: Light host controller reset is still ongoing.	RW	0
6	IAAD	Interrupt on Async Advance Doorbell  This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule.  Write 0x1: Ring the doorbell.  Software should not write a 1 to this bit when the asynchronous schedule is disabled. Doing so may yield undefined results.	RW	0
5	ASE	Asynchronous Schedule Enable  This bit controls whether the host controller skips processing the asynchronous schedule. 0x0: Do not process the asynchronous schedule 0x1: Use the USBHOST. <a href="#">ASYNCLISTADDR</a> register to access the asynchronous schedule.	RW	0
4	PSE	Periodic Schedule Enable  This bit controls whether the host controller skips processing the periodic schedule. 0x0: Do not process the periodic schedule 0x1: Use the USBHOST. <a href="#">PERIODICLISTBASE</a> register to access the periodic schedule.	RW	0
3:2	FLS	Frame List Size  This field specifies the size of the frame list. The size of the frame list controls which bits in the frame index register should be used for the frame list current index. 0x0: 1024 elements (4096 bytes) 0x1: 512 elements (2048 bytes) 0x2: 256 elements (1024 bytes), for resource-constrained environments 0x3: Reserved	RW	0

Bits	Field Name	Description	Type	Reset
1	HCR	Host Controller Reset  This control bit is used by software to reset the host controller. Write  0x1: Reset the host controller, the PCI configuration registers are not affected by this reset and all operational registers are set to their initial values.  This bit is set to 0 by the host controller when the reset process is complete.	W	0
0	RS	Run/stop  0x1: Run, the host controller proceeds with execution of the schedule. The host controller continues execution as long as this bit is set to 1.  0x0: Stop, the host controller completes the current and any actively pipelined transactions on the USB and then halts.	RW	0

RESERVED																ASS	PSS	REC	HCH	RESERVED				IAA	HSE	FLR	PCD	USBEI	USBI		

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0000
15	ASS	Asynchronous Schedule Status  The bit reports the current real status of the asynchronous schedule.  0x0: The status of the asynchronous schedule is disabled.  0x1: The status of the asynchronous schedule is enabled.	R	0
14	PSS	Periodic Schedule Status  The bit reports the current real status of the periodic schedule.  0x0: The status of the periodic schedule is disabled.  0x1: The status of the periodic schedule is enabled.	R	0
13	REC	Reclamation  It is used to detect an empty asynchronous schedule.	R	0
12	HCH	Host Controller Halted  This bit is a 0 whenever the USBHOST.USBCMD[0] RS bit is a 1. The host controller sets this bit to 1 after it has stopped executing as a result of the RS bit being set to 0, either by software or by the host controller hardware.	R	1
11:6	RESERVED	Reserved	R	0x00

Bits	Field Name	Description	Type	Reset
5	IAA	Interrupt on Async Advance  System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a 1 in the USBHOST.USBCMD[6] IAAD bit. This status bit indicates the assertion of that interrupt source.	RW	0
4	HSE	Host System Error  The host controller sets this bit to 1 when a serious error occurs during a host system access involving the host controller module.	RW	0
3	FLR	Frame List Rollover  The host controller sets this bit to 1 when the USBHOST.FRINDEX rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size.	RW	0
2	PCD	Port Change Detect  The host controller sets this bit to 1 when any port for which the USBHOST.PORTSC_i[13] PO bit is set to 0 has a change bit transition from a 0 to a 1 or a USBHOST.PORTSC_i[6] FPR bit transition from a 0 to a 1.  This bit is also set as a result of the USBHOST.PORTSC_i[1] CSC bit being set to 1 after system software has relinquished ownership of a connected port by writing a 1 to a USBHOST.PORTSC_i[13] PO bit.	RW	0
1	USBEI	USB Error Interrupt  The host controller sets this bit to 1 when completion of a USB transaction results in an error condition.	RW	0
0	USBI	USB Interrupt  The host controller sets this bit to 1 on completion of a USB transaction, which results in the retirement of a transfer descriptor that had its IOC bit set.  The host controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes).	RW	0

## 23.12 High-Speed USB OTG Controller

This section describes the high-speed USB On-The-Go (OTG) controller of the device.

---

**NOTE:** The high-speed USB OTG controller is an instantiation of the MUSBMHDC from Mentor Graphics Corporation.

This document contains materials that are ©2003-2007 Mentor Graphics Corporation.

---

### 23.12.1 High-Speed USB OTG Controller Overview

The High-Speed USB controller is a high-speed, USB OTG dual-role-device (DRD) link controller supporting the following modes:

- USB 2.0 peripheral (function controller) in high/full speed (480/12 Mbps, respectively)
- USB 2.0 host in high/full/low speed (480/12/1.5 Mbps, respectively), with one downstream port but multipoint capability when a hub is connected to it (split transaction support, etc.)
- USB 2.0 OTG DRD in high/full speed, with HNP (OTG1.3) and SRP support.

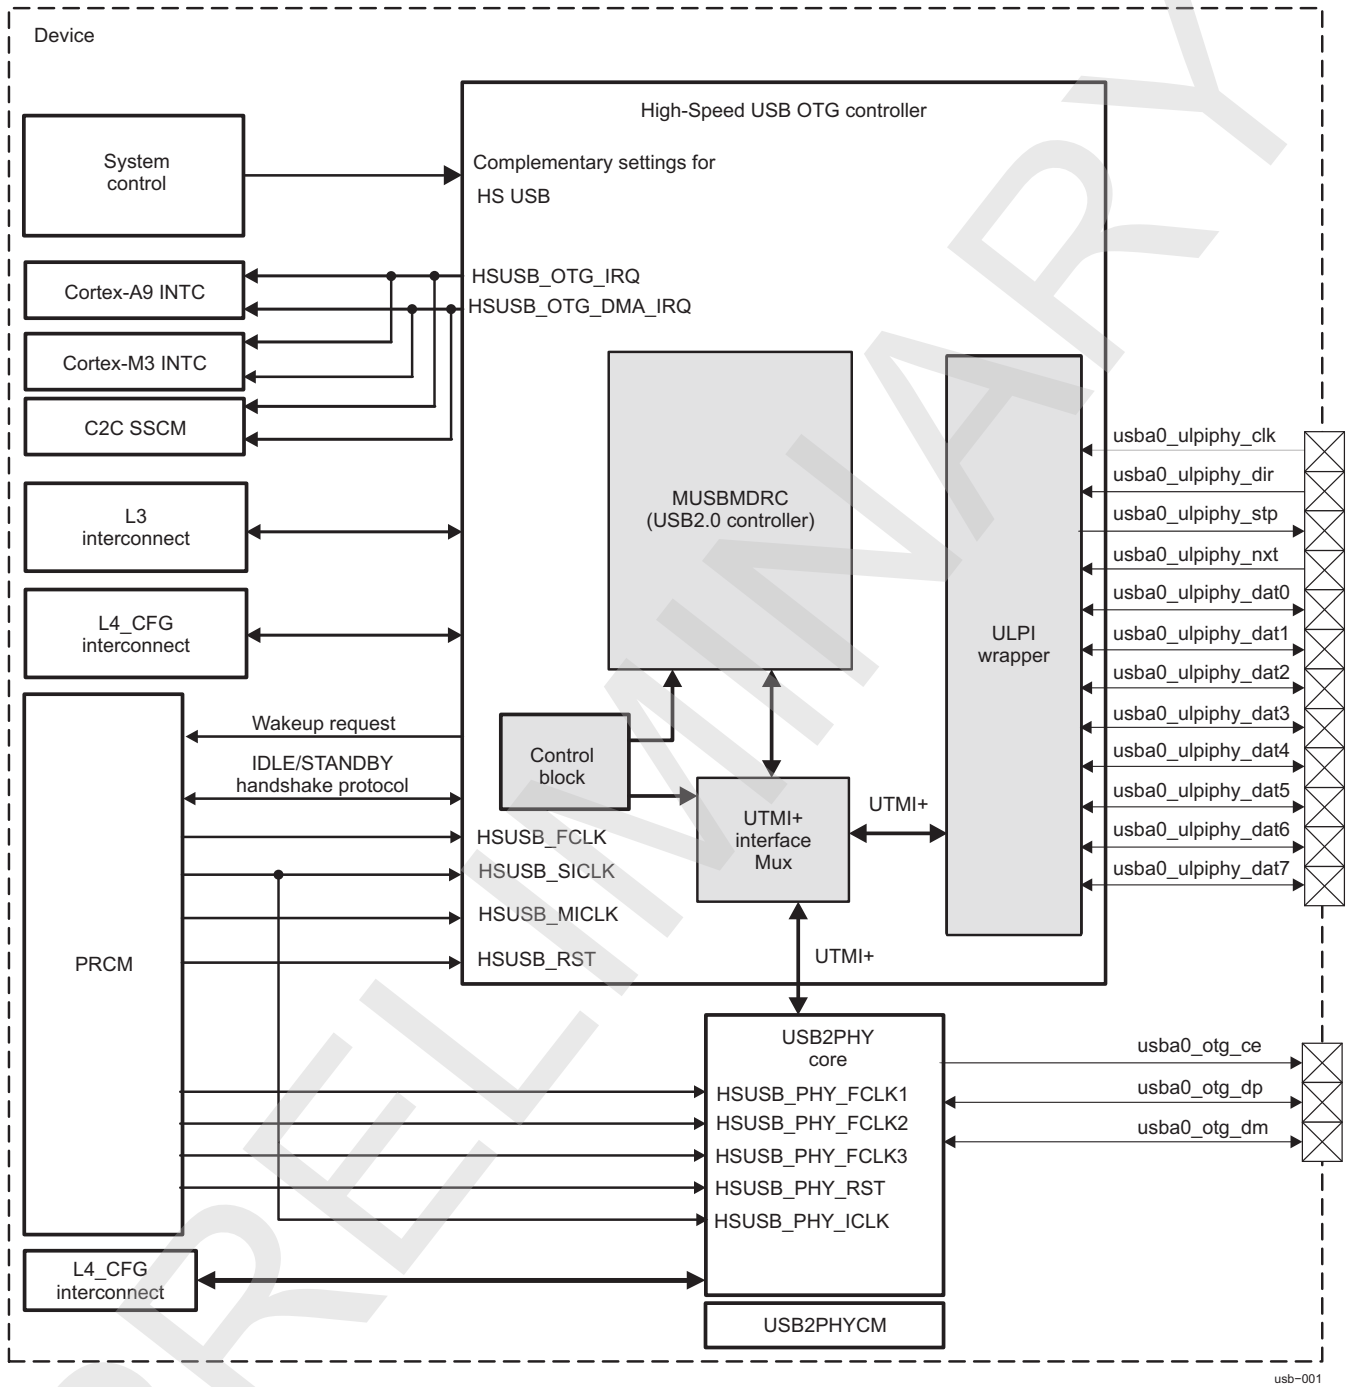

The high-speed USB OTG controller supports a single USB port, which uses the ULPI interface mode, to connect to an off-chip transceiver (12-pin/8-bit data SDR mode) and to connect on D+/D- (+ID) USB bus thanks to an embedded USB-HS OTG PHY.

It is connected to L3 master and L4 slave interfaces. It is clocked from independent functional clock from a PHY. This module operates either as the function controller of a high-/full-speed USB peripheral or as the host/peripheral in point-to-point or multi-point communications with other USB functions.

[Figure 23-258](#) highlights the high-speed USB controller.

Figure 23-258. High-Speed USB OTG Controller Highlight

### 23.12.1.1 Main Features

The high-speed USB controller features:

- L3 (master) interface supports:
  - 32-bit data bus width
  - 8/16/32 bit access supported
  - 32-bit address bus width
  - Burst supported
  - WNP not supported
- L4 (slave) interface supports:
  - 32-bit data bus width
  - 16/32 bit access supported
  - 12-bit address bus width
  - Burst not supported
  - WNP supported
- Complies with USB2.0 standard for high-speed (480 Mb/s) functions and with the OTG 1.3 (On-The-Go) supplement. Implement Link Power Management
- Contains embedded HS PHY with battery charger detection
- Contains PHY (physical layer) interface: ULPI interface (12-bit version)
- 15 transmit endpoints and 15 receive endpoints in addition to control endpoint 0
- Supports OTG communications with one or more high/full/low speed devices.
- Supports packet splitting / combining for bulk transfers
- Soft connect/disconnect option
- Performs all transaction scheduling in hardware
- Each endpoint can be configured for types (interrupt, bulk or isochronous), for size and double buffering operation within a limit of a 8KB of data and total RAM size of 16KB.
- Supports high-bandwidth isochronous and interrupt transfers.
- Supports suspend/resume and remote wake-up.
- Two interrupt lines.
- DMA access to endpoint FIFOs with internal DMA controller supporting 8 channels
- Supports host negotiation and session request protocols (HNP (OTG1.3) and SRP)
- CarKit feature implementation

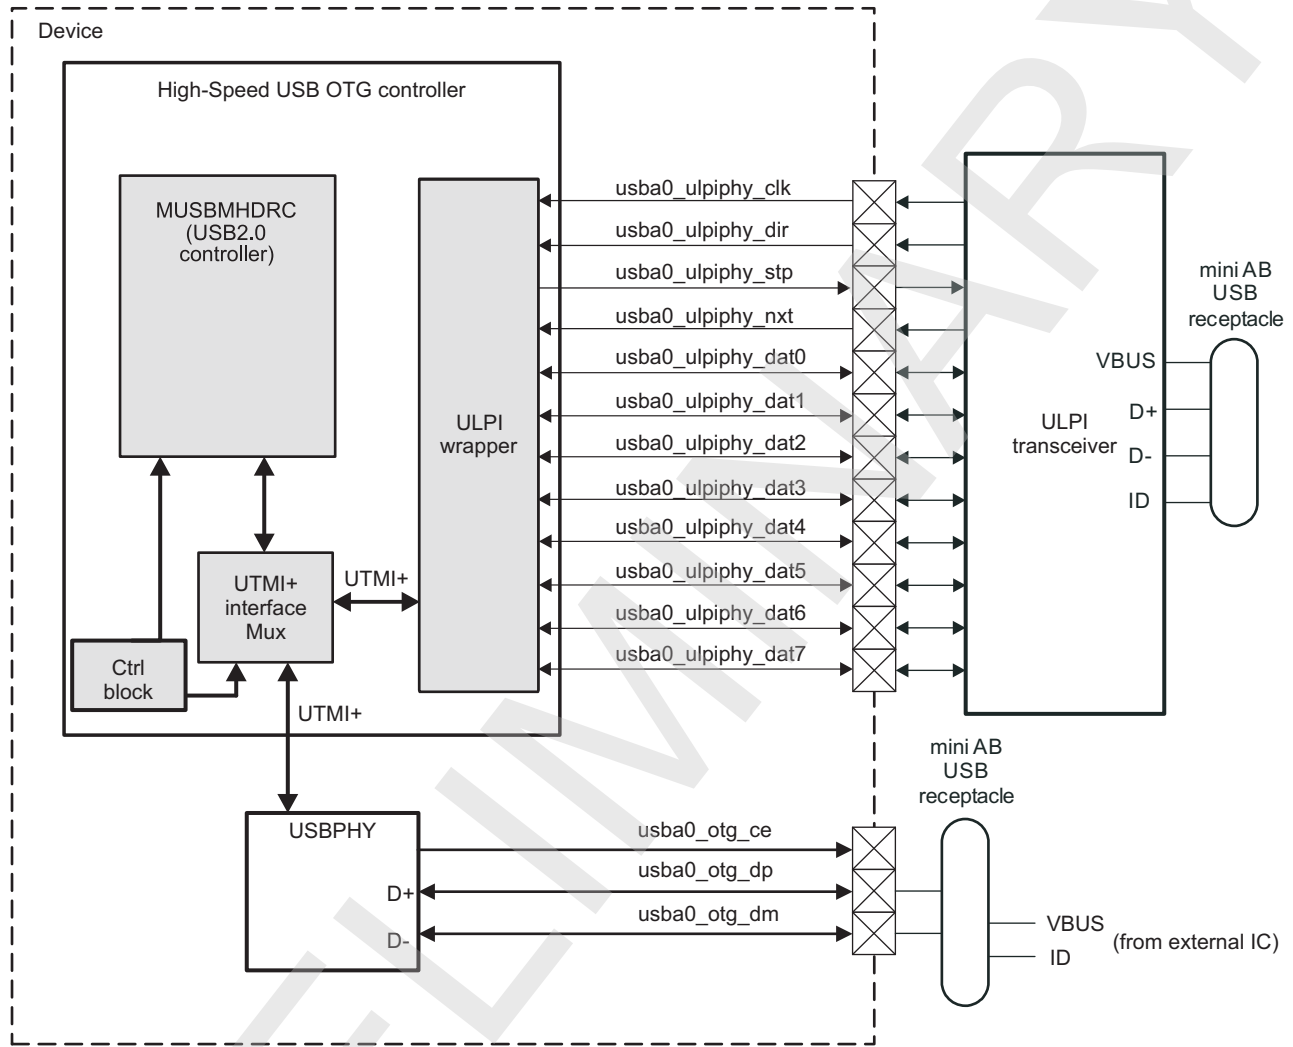

USB-HS OTG PHY (USBPHY). This embedded PHY is composed of two modules:

- USB2PHYCORE contains the USB functions, drivers, receivers and pads for correct D+/D– signalling and the battery charger detection (supporting dead-battery mode). Delivers a 3.3-V output signal (charger enable) to control external battery charger.
- USB2PHYCM contains LDO and bandgap for providing voltage reference to USB2PHYCORE module.

### 23.12.2 High-Speed USB OTG Controller Environment

Figure 23-259 shows a typical application using the high-speed USB controller.

Figure 23-259. High-Speed USB Controller Typical Application System

usb-002

**NOTE:** Only one interface can be active at a time.

The high-speed USB OTG controller supports a single USB port, which uses the ULPI interface mode, to connect to an off-chip transceiver (12-pin/8-bit data SDR mode). A mini A-B external receptacle allows the connection of an external device.

The 12-pin ULPI interface uses an 8-bit data bus with data synchronous to the rising edge of the PHY clock (SDR mode); the 8-pin ULPI uses a 4-bit data bus with data generated on both the rising and falling clock edge (DDR mode).

The current implementation of high-speed USB controller supports only the 12-pin, 8-bit version ULPI interface. The 12-pin/8-bit data SDR ULPI interface is selected through the `OTG_INTERFSEL[2:0]` PHYSEL field and must be set to 0x1.

Embedded PHY interface is 8-bit, UTMI+ and is selected through setting `OTG_INTERFSEL [2:0]` PHYSEL field to 0x0.

### 23.12.2.1 High-Speed USB OTG Controller Functional Interfaces

Table 23-1160 describes the I/O signals of the high-speed USB controller interfaces shown in Figure 23-259

**Table 23-1160. Input/Output Description**

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
usba0_ulpiphy_clk	I	Clock input from external transceiver <sup>(2)</sup>	HiZ
usba0_ulpiphy_dir	I	Data direction control from external transceiver	HiZ
usba0_ulpiphy_stp	O	Output to external transceiver to stop data stream	1
usba0_ulpiphy_next	I	Next signal control from external transceiver	HiZ
usba0_ulpiphy_dat0	I/O	Data 0 to/from external transceiver	HiZ
usba0_ulpiphy_dat1	I/O	Data 1 to/from external transceiver	HiZ
usba0_ulpiphy_dat2	I/O	Data 2 to/from external transceiver	HiZ
usba0_ulpiphy_dat3	I/O	Data 3 to/from external transceiver	HiZ
usba0_ulpiphy_dat4	I/O	Data 4 to/from external transceiver	HiZ
usba0_ulpiphy_dat5	I/O	Data 5 to/from external transceiver	HiZ
usba0_ulpiphy_dat6	I/O	Data 6 to/from external transceiver	HiZ
usba0_ulpiphy_dat7	I/O	Data 7 to/from external transceiver	HiZ
usba0_otg_ce	O	Charging Enable signal	0
usba0_otg_dp	I/O	USB Data +	HiZ
usba0_otg_dm	I/O	USB Data -	HiZ

<sup>(1)</sup> I = Input; O = Output

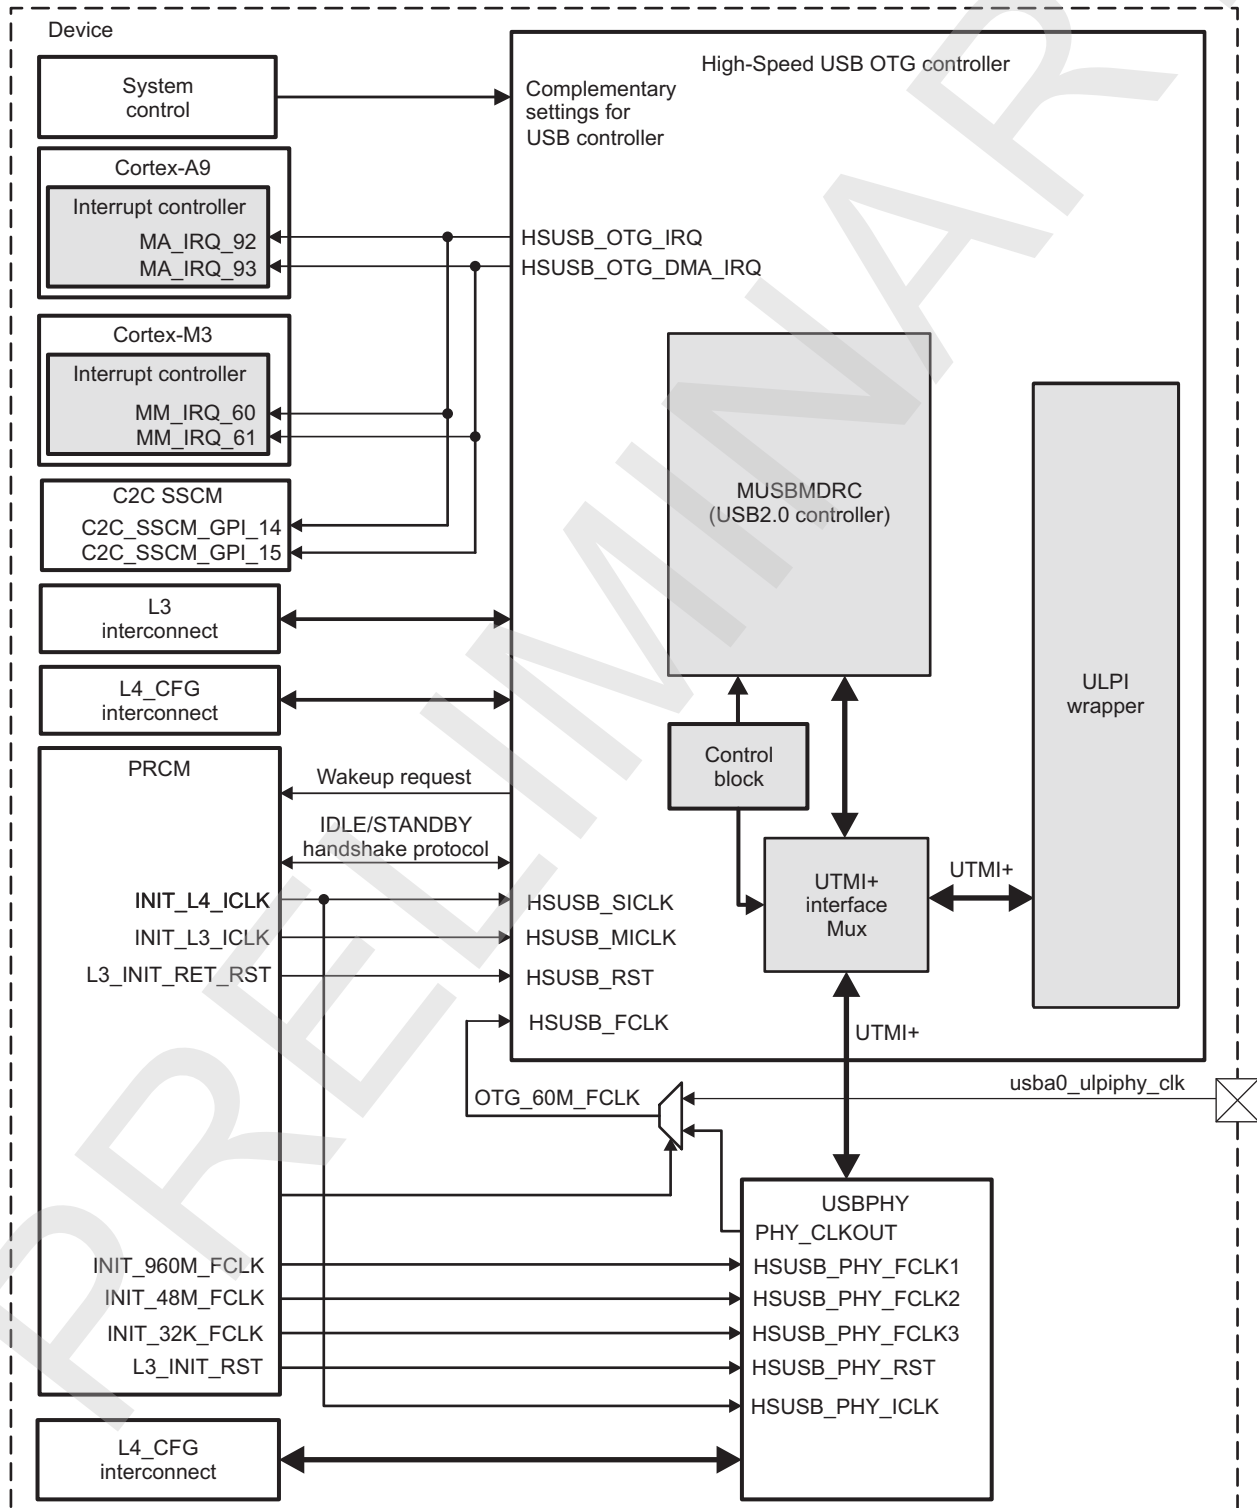

<sup>(2)</sup> This signal is also used as re-timing input.

### 23.12.3 High-Speed USB OTG Controller Integration

The L3 (master) interconnect generates data traffic within the device. The L4(slave) interconnect is a configuration port for register setting.

Figure 23-260 shows the high-speed USB controller integration in the device.

Figure 23-260. High-Speed USB Controller Integration

usb-003

Table 23-1161 through Table 23-1163 summarize the integration of the module in the device.

**Table 23-1161. Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
HSUSBOTG	PD_L3_INIT	L3 L4_CFG
USBPHY	PD_L3_INIT	L4_CFG

Three clocks are provided to the high-speed USB controller, as listed in Table 23-1162

**Table 23-1162. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
HSUSBOTG	HSUSB_FCLK	OTG_60M_FCLK	usb0_ulpiphy_clk/ USBPHY	Functional clock. Source is selected between external and embedded PHY. Section 3.6.3.2, <i>CM Clock Source</i> , in Chapter 3, <i>Power, Reset, and Clock Management</i> .
	HSUSB_SICLK	INIT_L4_ICLK	PRCM	L4 interconnect enable signal for the slave interface on L4 Section 3.6.3.2, <i>CM Clock Source</i> in Chapter 3, <i>Power, Reset and Clock Management</i>
	HSUSB_MICLK	INIT_L3_ICLK	PRCM	L3 interconnect clock, for the L3 master port interface Section 3.6.9, <i>CD_L3_INIT Clock Domain</i> in Chapter 3, <i>Power, Reset and Clock Management</i> .
USBPHY	HSUSB_PHY_FCLK1	INIT_960M_FCLK	PRCM	Functional clock
	HSUSB_PHY_FCLK2	INIT_48M_FCLK	PRCM	Optional functional clock
	HSUSB_PHY_FCLK3	INIT_32K_FCLK	PRCM	Optional functional clock
	HSUSB_PHY_ICLK	INIT_L4_ICLK	PRCM	Interface clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
HSUSBOTG	HSUSB_RST	L3_INIT_RET_RST	PRCM	HSUSBOTG controller hardware reset
USBPHY	HSUSB_PHY_RST	L3_INIT_RST	PRCM	USBPHY module hardware reset

Table 23-1163 lists the interrupt lines that are driven out from the high-speed USB controller.

**Table 23-1163. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
HSUSBOTG	HSUSB_OTG_IRQ	MA_IRQ_92	Cortex™-A9 INTC	HSUSBOTG interrupt request

## **23.12.4 High-Speed USB OTG Controller Functional Description**

### **23.12.4.1 Software Reset**

The high-speed USB controller has a software reset through the [OTG\\_SYSCONFIG\[1\] SOFTRESET](#) bit. Writing 0x1 to this bit initiates reset of the module. The bit value 0x1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically cleared to 0x0 and has the same effect as the hardware reset. The status of the reset can be observed through the [OTG\\_SYSSTATUS\[0\] RESETDONE](#) bit.

### **23.12.4.2 Power Management**

#### **23.12.4.2.1 Overview**

To save dynamic power consumption, an efficient idle scheme in the device is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated/deactivated safely without complex software intervention. In both cases, the high-speed USB controller power management is applied only to the interface clock domain. The USB OTG functional clock, HSUSB\_FCLK, is controlled by the transceiver and is responsible only for a very small percentage of the module overall power consumption.

The high-speed USB controller has both master (initiator) and slave (target) interfaces.

- As an initiator, the high-speed USB OTG controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the high-speed USB OTG controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

#### **23.12.4.2.2 System Power Management**

##### **23.12.4.2.2.1 Standby Handshake Protocol**

The high-speed USB OTG controller can choose to go to standby mode, in which case it stops generating transactions on the interconnect. The module standby leads the PRCM to disable the USB clocks to save power.

The high-speed USB OTG controller has a MSTANDBY handshake mechanism with the PRCM module

The module is ready to enter standby mode (indicated by the MSTANDBY signal to the PRCM asserted) when the USB is in suspend mode and the module is idle. It means the following:

- The module is committed not to start any new transaction on its master interface.
- The module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module to go to standby state based on the [OTG\\_SYSCONFIG\[13:12\] MIDDLEMODE](#) field.

- Smart-standby

The high-speed USB controller is configured in smart-standby mode ([OTG\\_SYSCONFIG\[13:12\] MIDDLEMODE](#) field = 0x2). The module is ready to enter standby mode (MSTANDBY is asserted) when there is no more activity on the USB master interface of the interconnect. MSTANDBY is asserted when the module is idle and deasserted when the module is activated by either an external USB event or an appropriate register access. The module then waits for MWAIT deassertion before a DMA transfer is started.

- Force-standby

– When the high-speed USB controller operates as a host: The USBOTG.POWER[1] SUSPENDMODE bit is set to 0x1 to bring the module to low-power mode (suspend mode). After this setting, the high-speed USB controller waits for its idle state. Software must set

**OTG\_SYSCONFIG**[13:12] MIDDLEMODE = 0x0. Hardware then asserts MSTANDBY. Similarly, to release the MSTANDBY signal, an appropriate register access must be applied, which can be either of the following two cases:

- Remote wakeup causes a RESUME interrupt
  - Set the USBOTG.POWER[3] RESET bit to 0x1
  - Write 0x2 to the **OTG\_SYSCONFIG**[13:12] MIDDLEMODE.  
OR
  - Set the USBOTG.POWER[3] RESET bit to 0x1
  - Write 0x2 to the **OTG\_SYSCONFIG**[13:12] MIDDLEMODE.
- When the high-speed USB controller operates as a peripheral: When the USB bus is idle for 3 ms, a SUSPEND interrupt is generated by the high-speed USB controller. Software must set **OTG\_SYSCONFIG**[13:12] MIDDLEMODE = 0x0. Hardware then asserts MSTANDBY. The high-speed USB controller then asserts MSTANDBY. Similarly, to release the MSTANDBY signal, an appropriate register access must be applied, which can be either of the following two cases:
- Set the USBOTG.POWER[2] RESUME bit to 0x1.
  - Write 0x2 to the **OTG\_SYSCONFIG**[13:12] MIDDLEMODE.  
OR
  - RESET interrupt is generated by the high-speed USB controller.
  - Write 0x2 to the **OTG\_SYSCONFIG**[13:12] MIDDLEMODE.

When MSTANDBY is deasserted as a consequence of the previous register access, the module waits for MWAIT deassertion before a DMA transfer is started.

- No-standby

The high-speed USB controller is configured in no-standby mode (**OTG\_SYSCONFIG**[13:12] MIDDLEMODE field = 0x1). The module never enters standby mode (that is, MSTANDBY is never asserted).

[Table 23-1164](#) describes the high-speed USB standby mode settings.

**Table 23-1164. HSUSBOTG Host Controller STANDBYMODE Settings**

<b>OTG_SYSCONFIG</b> [13:12] MIDDLEMODE Value	Selected Mode	Description
0x0	Force-standby	The HSUSBOTG host controller enters standby mode unconditionally
0x1	No-standby	The HSUSBOTG host controller never enters standby mode
0x2	Smart-standby	The HSUSBOTG host controller is ready to enter standby mode when there is no more activity on the USB master interface of the interconnect.

#### 23.12.4.2.2.2 IDLE Handshake Protocol

The high-speed USB controller can be configured through the **OTG\_SYSCONFIG**[4:3] SIDLEMODE field as one of the following acknowledgment modes:

- Smart-idle mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock INIT\_L3\_ICLK is disabled, see [Section 3.6.9, CD\\_L3\\_INIT Clock Domain](#)
- L4 interface clock idle transitions:

Configured in smart-idle mode (**OTG\_SYSCONFIG**[4:3] SIDLEMODE field = 0x2), the high-speed USB controller checks for no ongoing activity. The idle acknowledge then is asserted and the module waits for active system clock gating by the PRCM module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).

Once in smart idle mode (when the PRCM module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the module is ready to issue a wake-up request. If a wake-up condition occurs, the high-speed USB controller exits from smart idle mode if the **OTG\_SYSCONFIG**[2] ENABLEWAKEUP bit is set to 0x1 (wake-up capability enabled).

- Smart-idle wake-up mode  
The high-speed USB OTG controller is configured in smart-idle wake-up mode (**OTG\_SYSCONFIG**[4:3] Smart Idle Wkp field = 0x3). The functionality of this mode is the same as smart-idle mode, additionally Wake up feature is enabled.
- Force-idle mode  
When the high-speed USB controller receives an IDLE request from the PRCM module:
  - The interface clock INIT\_L3\_ICLK is disabled, see [Section 3.6.9, CD\\_L3\\_INIT Clock Domain](#)
  - The L4 interface clock idle transitions:  
Configured in force-idle mode (**OTG\_SYSCONFIG**[4:3] SIDLEMODE field = 0x0), the high-speed USB controller waits unconditionally for active system clock gating by the PRCM module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).  
Once in idle mode (when the PRCM module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the wake-up feature is totally inhibited.
- No-idle mode  
When the high-speed USB controller receives an IDLE request from the PRCM module:
  - The interface clock INIT\_L3\_ICLK is disabled [Section 3.6.9, CD\\_L3\\_INIT Clock Domain](#)
  - L4 interface clock idle transitions  
Configured in no-idle mode (**OTG\_SYSCONFIG**[4:3] SIDLEMODE bit field = 0x1), the high-speed USB controller module does not go to idle mode and the idle acknowledge is never sent.

[Table 23-1165](#) describes the high-speed USB sidle mode settings. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

**Table 23-1165. HSUSBOTG Host Controller SIDLEMODE Settings**

<b>OTG_SYSCONFIG</b> [4:3] <b>SIDLEMODE Value</b>	<b>Selected Mode</b>	<b>Description</b>
0x0	Force-idle	The HSUSBOTG host controller acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations.
0x1	No-idle	The HSUSBOTG host controller never acknowledges any IDLE request from the PRCM.
0x2	Smart-idle	The HSUSBOTG host controller acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated.
0x3	Smart-idle wake-up	The HSUSBOTG host controller enters smart mode with wakeup enabled.

#### 23.12.4.2.2.3 Wake-Up Request

Wake-up request is enabled by setting **OTG\_SYSCONFIG**[2] ENABLEWAKEUP to 0x1. The enable wake-up feature works only when smart-idle wakeup is enabled.

#### 23.12.4.2.3 Local Power Management

The high-speed USB OTG controller has local power management by internal clock gating features:

- Internal interface clock autogating: Clock for the L3 interconnect logic can be gated when the module is not accessed, if the **OTG\_SYSCONFIG**[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock. This bit is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

#### 23.12.4.3 Inventra MUSBMHDC

The core functionality of the module is provided by a third-party IP, the Inventra™ MUSBMHDC from Mentor Graphics® Corporation.

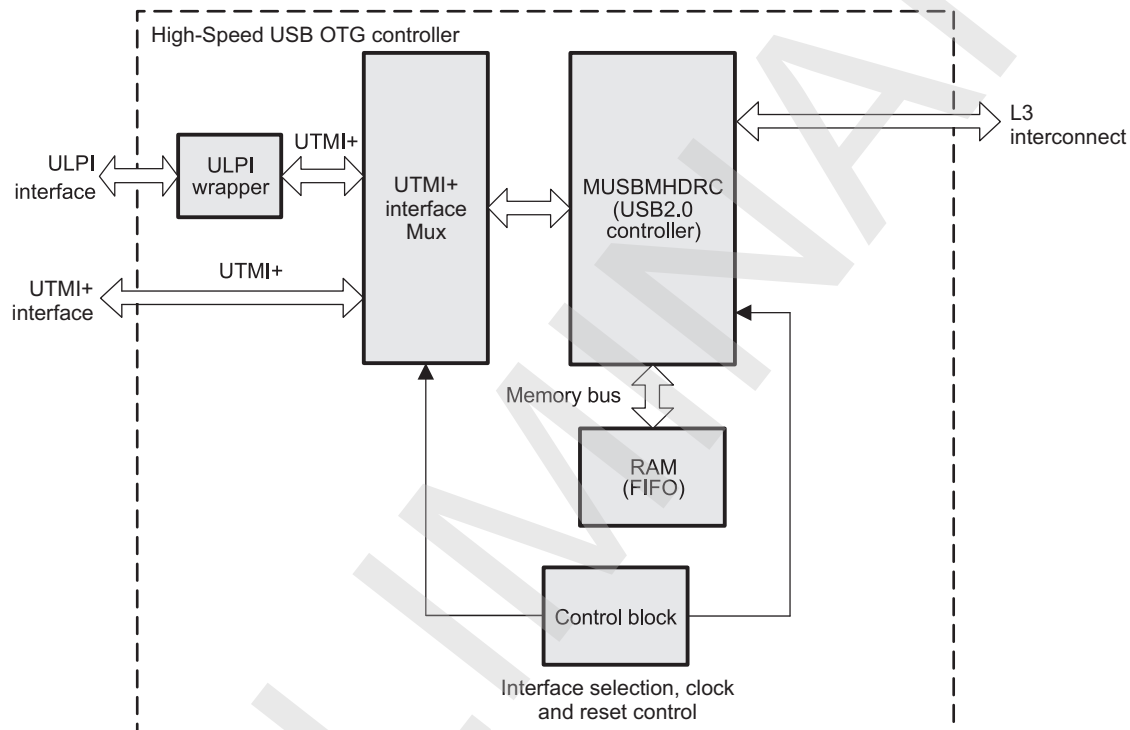

The high-speed USB OTG controller is basically the appropriate adaptation/integration of this IP to comply with TI requirements.

The high-speed USB OTG controller includes the following:

- MUSBMHDRC (USB 2.0 controller)
- Master and slave bridges for conversion AHB to L3 interconnect and L3 interconnect to AHB
- Built-in self-test (BIST) controller
- Two memories (total of 16KB; available for various endpoints)
- Reset and clock generation
- DFT compliance with regards to latest specs

Figure 23-261 shows the high-speed USB controller.

**Figure 23-261. High-Speed USB OTG Controller**

usb-004

#### 23.12.4.4 Configuration

The following options are implemented in the TI high-speed USB OTG controller:

- 8-bit internal data path processing width (mandated by the use of ULPI)
- 32-bit vcontrol/vstatus support
- External charge pump: Hacked
- Software connect/disconnect supported
- Little-endian and big-endian byte ordering
- Eight DMA channels (with internal DMA initiator implemented)
- Dynamic FIFO sizing enabled
- 16-KB RAM buffer
- 15 IN/OUT endpoints in addition to control endpoint 0
- IN/OUT bulk packet splitting enabled
- High-bandwidth IN/OUT isochronous support enabled (see *Universal Serial Bus Specification Revision 2.0*)

#### 23.12.4.5 Basic Operation

This section provides an overview of the module basic operation.

To implement the most time-critical functions in hardware, the module provides all of the encoding, decoding, and checking required to send and receive USB packets, interrupting the MPU only when endpoint data is successfully transferred. Generally, the following steps are performed.

##### 23.12.4.5.1 Module Initialization

First, the firmware must do the overall initialization of the module by configuring the interrupts, DMA controller, and individual endpoints.

The specific items of a configuration for each endpoint are:

- Direction TX/RX
- Speed: High/full/low
- Special host settings when used in host mode (function address/hub parameters, etc.)
- Transaction protocol: Control/isochronous/bulk/interrupt
- Maximum packet size, that can be transferred through the endpoint
- Whether DMA is required (DMA enable)
- DMA mode
- Start address of the endpoint FIFO within the RAM block
- Maximum packet size allowed
- Whether double-buffering is required. This and the previous option define the amount of space that must be allocated to the FIFO. In the case of double-buffering, the FIFO size is doubled; therefore, the maximum supported size is 8196 bytes for the endpoint FIFOs.

---

**NOTE:** On the system level, it must be ensured that the reset and the interface are selected before the functional clock (OTG\_60M\_FCLK) is applied to the module. Correct functionality is not ensured if a reset deassertion or a change in the interface selection occurs when the functional clock OTG\_60M\_FCLK is already running.

---

##### 23.12.4.5.2 Transaction Handling

Depending on whether the module is in the host or peripheral mode, an RX endpoint is assigned to IN or OUT transactions, respectively. Similarly, a TX endpoint is used for IN transactions in the peripheral mode and for OUT transactions in the host mode. When a transaction is complete, the appropriate endpoint interrupt is generated (if enabled).

When a transaction is handled through an RX endpoint, the received packet is placed in the RX FIFO, and

the appropriate RX endpoint interrupt is generated. The packet can then be unloaded from the FIFO either manually (that is, by the MPU) or by the DMA. Although an RX endpoint is always active for a peripheral, in host mode the transaction must first be initiated by setting the appropriate request flag (REQPKT). This indicates to the transaction scheduler that there is an active transaction on this endpoint, which requires an IN token to be sent to the target function.

When a transaction is handled through a TX endpoint, the packet to send is loaded into the TX FIFO either manually (that is, by the MPU) or by the DMA. The transaction then must be initiated by setting the appropriate ready flag (TXPKTRDY) to indicate the availability of the new packet. When the packet is successfully sent (scheduled according to the protocol rules), the appropriate TX interrupt is generated.

### 23.12.4.6 Optional Features

This section gives a quick overview of the optional features that are available, depending on the endpoint configuration.

#### 23.12.4.6.1 Double Packet Buffering

When double packet buffering is enabled (by setting the MSB of the FIFOSZ register) two data packets can be stored in the FIFO. This option can be set for both the TX and RX endpoints in both the peripheral and host mode. For a TX endpoint, double-buffering means that up to two packets can be loaded into the FIFO awaiting transmission; for an RX endpoint, one packet can be received while another is being read. Double packet buffering is especially advisable for isochronous transactions to avoid underrun or overrun errors.

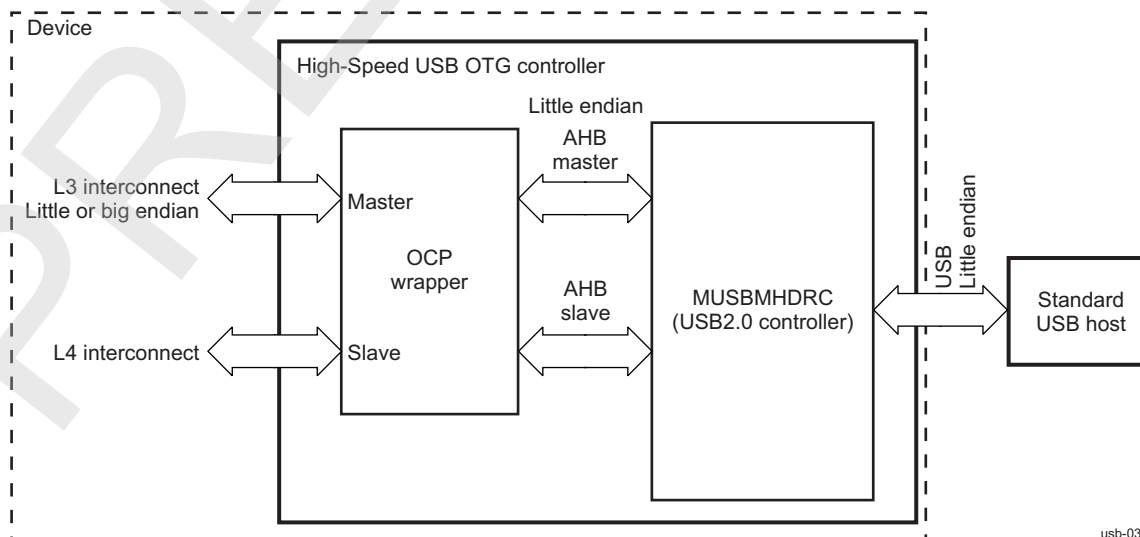

The high-speed USB controller provides dynamic FIFO sizing with an overall RAM size of 16KB, which can then be allocated to the different endpoints when the module is initialized. The maximum size of an endpoint FIFO is 4096 bytes for single packet buffering and 8192 bytes for double packet buffering. The firmware must ensure that a block of RAM is properly assigned to all TX and RX endpoints, considering the total RAM size and the maximum packet size set for the endpoint.

#### 23.12.4.6.2 USBOTGHS Support for Big Endian

In the example in [Figure 23-262](#), the high-speed USB OTG controller module is configured as a USB device and is connected to a standard USB host. The two interconnect interfaces of the high-speed USB OTG controller connect it to the system bus. The register read/write is performed through the interconnect slave interface (control path). The data transfer to/from system memory takes place through the interconnect master interface (data path).

The data transfer on USB is always in little-endian mode, but on interconnect it can be in little- or big-endian mode, as shown in [Figure 23-262](#).

**Figure 23-262. High-Speed USB OTG Controller Endianness**

usb-036

Big-endian support in the high-speed USB OTG controller may or may not require byte-swapping in the data path. Byte-swapping is performed based on the unit size of data. For example, if multiple bytes are packed into a single 32-bit word, these bytes must be swapped in a big-endian interconnect. On the other hand, if the data is simply a 32-bit word (for example, a 32-bit descriptor pointer in a memory buffer), the bytes in the word must not be swapped in big-endian mode.

In the high-speed USB OTG controller, the unit size of descriptors/descriptor pointers is 32 bits, and the unit size of USB data is 8 bits. Four 8-bit USB data are packed to form a 32-bit word. This 32-bit data requires byte-swapping, whereas the descriptors/descriptor pointers do not require byte-swapping.

---

**NOTE:** Byte-swapping is not required in the control path (slave interface).

---

The interconnect master interface (a submodule within the interconnect wrapper) supports big-endian conversion by setting the `OTG_BIGENDIAN[0]` `BIG_ENDIAN` bit to 0x1.

For interconnect write transactions, the data word is swapped, as shown in [Table 23-1166](#), before its output on the interconnect master interface. In case of an interconnect read transaction, the received data is swapped before its output on the AHB master interface of the MUSBMHDCR core. The interconnect `MByteEn` is swapped before the command is issued on the interconnect master interface. The interconnect `MAddr` is always aligned to the size of the interconnect data (32 bits). Hence, the interconnect `MAddr` is always word-aligned.

**Table 23-1166. Interconnect Data and MByteEn in Little- and Big-Endian Modes**

Unit Size of Data	AHB Size (of Packed/Nonpacked Data)	AHB Start Address Offset (Always in Little-Endian Mode)	Interconnect MByteEn in Little-Endian Mode	Interconnect MByteEn in Big-Endian Mode	Interconnect Data in Little-Endian Mode	Interconnect Data in Big-Endian Mode
Byte	Byte	0	0001	1000	xxx <b>b</b> 0	b0xxx
Byte	Byte	1	0010	0100	xxb0x	xb0xx
Byte	Byte	2	0100	0010	xb0xx	xxb0x
Byte	Byte	3	1000	0001	b0xxx	xxx <b>b</b> 0
Byte	Half-word	0	0011	1100	xxb1b0	b0b1xx
Byte	Half-word	2	1100	0011	b1b0xx	xxb0b1
Byte	Word	0	1111	1111	b3b2b1b0	b0b1b2b3
Half-word	Half-word <sup>(1)</sup>	0	0011	1100	xxb1b0	b1b0xx
Half-word	Half-word <sup>(1)</sup>	2	1100	0011	b1b0xx	xxb1b0
Half-word	Word <sup>(1)</sup>	0	1111	1111	b3b2b1b0	b1b0b3b2
Word	Word <sup>(2)</sup>	0	1111	1111	b3b2b1b0	b3b2b1b0

<sup>(1)</sup> Not a likely scenario for high-speed USB OTG controller

<sup>(2)</sup> Corresponds to descriptor and descriptor pointer. No bytes are packed to form a word; hence, no byte-swapping is done in this case.

### 23.12.4.6.3 DMA

The high-speed USB controller has an internal DMA controller for efficient loading/unloading of the endpoint FIFOs. The DMA controller is configured for 8 channels and it has its own block of control registers and its own interrupt controller

If the DMA is enabled for a TX endpoint, a DMA transfer occurs whenever the endpoint can accept another packet in its FIFO (that is, the DMA controller loads the packets into the FIFO without processor intervention).

If the DMA is enabled for an RX endpoint, a DMA transfer occurs whenever the endpoint has a packet in its FIFO (that is, the DMA CONTROLLER unloads the packets from the FIFO without processor intervention).

The high-speed USB controller supports two DMA request modes, which also affects the generation of endpoint interrupts.

- DMA request mode 0 is especially advisable for isochronous transfers but can also be used for bulk and interrupt transfers.
- DMA request mode 1 is mainly valuable for bulk transfers, where typically a large block of data is split into a series of packets of the maximum size.

#### 23.12.4.6.3.1 DMA Request Mode 0

For RX endpoints, the DMA transfer is initiated when a data packet is available in the endpoint FIFO. The appropriate endpoint interrupt is also generated after the packets are received.

For TX endpoints, the DMA transfer is initiated when the endpoint FIFO can accept a data packet. The appropriate endpoint interrupt is also generated to prompt the loading of the packets.

#### 23.12.4.6.3.2 DMA Request Mode 1

For RX endpoints the DMA transfer is initiated only when the received packet is the maximum packet size (as set in the RXMAXP register for the corresponding endpoint). The appropriate endpoint interrupt is generated only when the received packet is a short packet (that is, one less than the maximum packet size); otherwise, it is suppressed.

For TX endpoints, the DMA transfer is initiated when the endpoint FIFO can accept a data packet. The appropriate endpoint interrupt is suppressed.

#### 23.12.4.6.3.3 Internal DMA Controller

The high-speed USB controller has an internal DMA controller to perform DMA transfers acting as host on the L3 interconnect. The DMA controller has eight channels, which can be independently programmed based on the following configuration options:

- DMA enable
- Direction (DMA write/DMA read)
- DMA mode (transfer one or more packets)
- Interrupt enable
- Endpoint number
- L3 interconnect memory address (32 bits)
- Byte count

The DMA controller can issue single accesses (8-bit, 16-bit, or 32-bit) and also bursts (4 × 32-bit, 8 × 32-bit, or 16 × 32-bit) on the L3 interconnect. The start address provided to the DMA controller must be 32-bit aligned.

#### 23.12.4.7 Automatic Packet Splitting/Combining for Bulk Transfers

The high-speed USB controller offers the facility for bulk endpoints to store larger amounts of data in their FIFOs than can be transferred in a single USB operation. In other words, the module includes a configuration option that, if selected, allows larger data packets to be written to bulk TX endpoints, which are then split into packets of an appropriate size for transfer across the USB. A similar option exists for bulk RX endpoints, which, if selected, causes the module to combine the packet received across the USB into larger data packets before being read by the application software.

The firmware can enable these options by setting the corresponding bits (MPRXE and MPTXE) in the CONFIGDATA register. The necessary packet size information contains the payload size for one transaction and a multiplier defining the maximum number of USB packets. The payload is required to be either 8, 16, 32, 64, or (in case of high-speed transfers) 512 bytes; the multiplier can be any value up to 32.

#### 23.12.4.8 High-Bandwidth Isochronous Endpoints

In the high-speed mode, isochronous endpoints can transfer up to three USB packets in any microframe with a payload of up to 1024 bytes in each packet, corresponding to a data transfer rate of up to 3072 bytes per microframe (see *Universal Serial Bus Specification Revision 2.0*).

For TX endpoints, the high-speed USB controller supports this by allowing loading data packets of up to 3072 bytes (that is,  $3 \times 1024$  bytes) into the associated endpoint FIFO, which is then automatically split into USB packets of the maximum payload, or smaller to be transmitted in one microframe.

For RX endpoints, the module automatically combines all the USB packets received during a microframe into a single packet of up to 3072 bytes (that is,  $3 \times 1024$  bytes) within the RX FIFO.

The number of USB packets transferred per microframe and the maximum payload in each packet is defined through the appropriate registers (RXMAXP and TXMAXP).

#### 23.12.4.9 Carkit Implementation

Carkit feature implementation:

UART3 RX/TX muxing on the `usba0_ulpiphy_dat0` and `usba0_ulpiphy_dat1`. To support carkit interrupt through `USB0HS.DATA3`, three different methods can be used:

- External PHY interrupt if provided: `IRQ_SYS` interrupt
- UART3 interrupt: CTS edge detection
- GPIO interrupt: Edge detection on GPIO associated to `usba0_ulpiphy_dat3` line

#### 23.12.4.10 USB PHY

The device-embedded USB PHY is composed of the following modules:

- **USB2PHYCORE**: Contains the USB functions, drivers, receivers, and pads for correct D+/D– signaling, and the battery charger detection (supporting dead-battery mode). Delivers a 3.3-V output signal (charger enable [pin `usba0_otg_ce`]) to control an external battery charger.
- **USB2PHYCM**: Contains LDO and bandgap to provide voltage reference to the **USB2PHYCORE** module

The embedded PHY does not support the OTG features of USB-OTG standards (that is, ID pin detection and VBUS detection). This function is exported to an external companion chip (for example, the TWL6030). Software must retrieve the OTG HNP and SRP status from the TWL6030 (using the I2C1 interface) and configure the bits inside the control module that drive the related USBOTGHS UTMI+ interface signals. It must also read back the UTMI+ signals needed to configure the TWL6030 OTG module.

These signals are:

- Inputs of the USB controller driven by the control module:
  - `Avalid`: Indicates whether VBUS is above the A-Device session valid threshold
  - `Bvalid` (currently not used)
  - `Vbusvalid`: Indicates whether VBUS is above the threshold for normal operation
  - `Sessend`: Indicates whether VBUS is below the B-Device session end threshold
  - `Iddig`: Indicates the value of the ID pin of the USB connector
- Outputs of the USB controller readable in the control module:
  - `Idpullup`: Enables sampling of the ID pin of the USB connector
  - `Drv vbus`: Controls the driving of 5-V power on VBUS
  - `Chrg vbus`: Controls the charging of VBUS for initiating SRP
  - `Dischrg vbus`: Controls the discharging of VBUS for completing SRP

See the `CONTROL_USBOTGHS_CONTROL` register in [Chapter 18, Control Module](#), and the TWL6030 TRM.

The following UTMI signals are not connected:

- `Txbitstufferable` (no bit-stuffing out from the USB controller)
- `Txbitstufferableh` (because only 8 bits are used)

The following USBPHY signals are routed internally to the GPIO6 module pins to generate interrupts when any of the following events occur:

- **CHGDETECTED**: This signal indicates the output of the charger detection protocol.  
0: Charger not detected

1: Charger detected

The value is latched until the charger protocol is reset.

- **DPDM5VSHORT:** This signal is asserted high if a short-circuit-to-VBUS condition is detected on the USB DP or DM pins. This signal is valid only if all power supplies are present. The short is detected if any or even none of the supplies are present.

0: No short

1: VBUS short on DP or DM detected

For information about how to enable these interrupts, see [Chapter 25, General-Purpose Interface](#).

### 23.12.5 High-Speed USB OTG Controller Basic Programming Model

This section describes the low-level hardware programming sequences for configuration and use of the high-speed USB OTG controller.

#### 23.12.5.1 Global Initialization

##### 23.12.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the high-speed USB OTG controller is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the high-speed USB OTG controller.

**Table 23-1167. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	All required clocks must be enabled, see <a href="#">Table 23-1162</a> . Do not apply OTG_60M_FCLK clock before the interface is selected. Refer to the <a href="#">Section 3.6.3.2</a>
Cortex-A9 MPU INTC or Cortex-M3 MPU INTC	Cortex-A9 MPU or Cortex-M3 MPU interrupt controller must be configured to enable the interrupt request generation to the Cortex-A9 MPU or Cortex-M3 MPU subsystem when interrupt requests are generated by the High-Speed Multiport USB Host Subsystem. See the respective Functional Description in the Interrupt Controller chapter for the MPUs.
Interconnect (L3 and L4)	See <a href="#">Section 13.2, L3 Interconnect</a> , and <a href="#">Section 13.3, L4 Interconnect</a> , for more information.

##### 23.12.5.1.2 High-Speed USB OTG Controller Global Initialization

This procedure initializes the high-speed multiport USB host subsystem after a power-on or software reset. The module USBPHY is reset through boundary reset signal L3\_INIT\_RST coming from PRCM module.

**Table 23-1168. High-Speed USB OTG Software Reset**

Step	Register/Bit Field/Programming Model	Value
Perform a software reset on the USB OTG controller	OTG_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is finished	OTG_SYSSTATUS[0] RESETDONE	=0x1

**Table 23-1169. Power Management Configuration**

Step	Register/Bit Field/Programming Model	Value
Select master interface standby mode	OTG_SYSCONFIG[13:12] MIDLemode	0x-
Select slave interface idle mode	OTG_SYSCONFIG[4:3] SIDLemode	0x-
Set clock autogating	OTG_SYSCONFIG[0] AUTOIDLE	0x-

### 23.12.5.2 High-Speed USB OTG Controller Interface Modes

This procedure describes TI high-speed USB controller interface selection:

**Table 23-1170. High-Speed USB Controller Interface Selection**

Step	Register/Bit Field/Programming Model	Value
Select between embedded and external PHY interface	<a href="#">OTG_INTERFSEL</a> [2:0] PHYSEL	0x-
Enable functional PHY clock (OTG_60M_FCLK)	Refer to <a href="#">Section 3.6.3.2</a>	-

### 23.12.5.3 High-Speed USB OTG Controller Power Management Configuration

This section describes the settings for optimal high-speed USB controller power management, depending on the use of this module in the application.

#### 23.12.5.3.1 No Application Mode

The optimal configuration when the high-speed USB controller is not used by the application is as follows:

**Table 23-1171. Power Management Configuration - No Application Mode**

Step	Register/Bit Field/Programming Model	Value
Switch master interface to force standby mode	<a href="#">OTG_SYSCONFIG</a> [13:12] MIDDLEMODE	0x0
Switch slave interface to force-idle mode	<a href="#">OTG_SYSCONFIG</a> [4:3] SIDLEMODE	0x0
Set the clock to smart mode - clock is cut-off if no activity on the interface	<a href="#">OTG_SYSCONFIG</a> [0] AUTOIDLE	0x1

#### 23.12.5.3.2 Host or Peripheral Mode

When used as a host or in peripheral mode, the high-speed USB controller must be programmed as follows:

**Table 23-1172. Power Management Configuration - Host or Peripheral Mode**

Step	Register/Bit Field/Programming Model	Value
Switch Master interface to smart standby mode	<a href="#">OTG_SYSCONFIG</a> [13:12] MIDDLEMODE	0x2
Switch Slave interface to smart-idle mode	<a href="#">OTG_SYSCONFIG</a> [4:3] SIDLEMODE	0x2
Set the clock to smart mode - clock is cut-off if no activity on the interface	<a href="#">OTG_SYSCONFIG</a> [0] AUTOIDLE	0x1

#### 23.12.5.3.3 Switching Between Host and Peripheral Mode

When used as a host/peripheral, the high-speed USB OTG controller must be programmed as follows:

**Table 23-1173. Power Management Configuration - Switching Between Host and Peripheral Mode**

Step	Register/Bit Field/Programming Model	Value
Switch Master interface to force standby mode	<a href="#">OTG_SYSCONFIG</a> [13:12] MIDDLEMODE	0x0
Switch Slave interface to smart-idle mode	<a href="#">OTG_SYSCONFIG</a> [4:3] SIDLEMODE	0x2
Set the clock to smart mode - clock is cut-off if no activity on the interface	<a href="#">OTG_SYSCONFIG</a> [0] AUTOIDLE	0x1

### 23.12.6 High-Speed USB OTG Controller Register Manual

This section presents only the TI-specific registers of the high-speed USB controller.

[Table 23-1174](#) lists the base address and address space for the high-speed USB controller.

**Table 23-1174. High-Speed USB OTG Controller Instance Summary**

Module Name	Base Address	Size
HSUSBOTG	0x4A0A B000	4KB
USBPHY	0x4A0A D000	4KB

**CAUTION**

The high-speed USB registers are limited to 32-bit data accesses; 16-bit and 8-bit accesses are not allowed and can corrupt register content.

<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESTART_HSRX_CAL	USE_HS_OFF_REG	HS_OFF_CODE						HSRX_COMP_OUT	HSRX_CAL_DONE	USE_SQ_OFF_DAC1	SQ_OFF_CODE_DAC1						USE_SQ_OFF_DAC2	SQ_OFF_CODE_DAC2						USE_SQ_OFF_DAC3	SQ_OFF_CODE_DAC3						SQ_COMP_OUT	SQ_CAL_DONE	RESTART_SQ_CAL

Bits	Field Name	Description	Type	Reset
31	RESTART_HSRX_CAL	Restart the HSRX calibration state machine when this bit goes from 0 to 1.	RW	0
30	USE_HS_OFF_REG	Override HS offset correction with HS_OFF_CODE when set to 1	RW	0
29:24	HS_OFF_CODE	HS offset code, this code is forced when bit 30 is 1. Code is updated from calibration logic when bit 30 = 0.	RW	0x00
23	HSRX_COMP_OUT	The output of the HSRX comparator. Read value is valid only if VDDLDO is on.	R	0
22	HSRX_CAL_DONE	Signal that indicates that the HSRX calibration is done. This gets reset at every restart. Read value is valid only if VDDLDO is on.	R	0
21	USE_SQ_OFF_DAC1	Override Squelch offset DAC1 code when '1'	RW	0
20:15	SQ_OFF_CODE_DAC1	When read returns current Sq offset code for DAC1, if VDDLDO is on. When written this is used as Sq offset code for DAC1 when USE_SQ_OFF_DAC1 = 1	RW	0x00
14	USE_SQ_OFF_DAC2	Override Squelch offset DAC2 code when '1'	RW	0
13:9	SQ_OFF_CODE_DAC2	When read returns current Sq offset code for DAC2, if VDDLDO is on. When written this is used as Sq offset code for DAC2 when USE_SQ_OFF_DAC2 = 1	RW	0x00
8	USE_SQ_OFF_DAC3	Override Squelch offset DAC3 code when 1	RW	0

Bits	Field Name	Description	Type	Reset
7:3	SQ_OFF_CODE_DAC3	When read returns current Sq offset code for DAC3, if VDDLDO is on. When written this is used as Sq offset code for DAC3 when USE_SQ_OFF_DAC3 = 1	RW	0x00
2	SQ_COMP_OUT	Sq comp output. Read value is valid only if VDDLDO is on.	R	0
1	SQ_CAL_DONE	Sq calibration is done when this bit = 1. See RESTART_SQ_CAL for more description. Read value is valid only if VDDLDO is on.	R	0
0	RESTART_SQ_CAL	The squelch calibration continuously goes through restart cycles when this bit is 1.	RW	0

## 23.13 Full-Speed USB Host Controller

This section describes the full-speed universal serial bus (FSUSB) host controller for the device

### 23.13.1 FSUSB Host Controller Overview

**NOTE:** Copyright ©2004, 2005, 2006, 2007, 2008 Synopsys, Inc. All rights reserved. Used with permission.

This module is a full-speed universal serial bus (FSUSB) host controller which complies with the USB 2.0 standard for full-speed functions. The FSUSB host controller supports a single universal serial bus (USB) host port with a USB interchip to interface with a multimedia subscriber-identity module (SIM) card, using 2-/4-pin bidirectional mode (host mode).

The FSUSB host controller has level 3 (L3) and level 4 (L4) interfaces with an independent functional clock.

**Figure 23-263. FSUSB Host Controller Overview**

fsusb-001

#### 23.13.1.1 Main Features

The main features of the FSUSB host controller include:

- USB host
  - Compatible with OHCI Rev 1.0

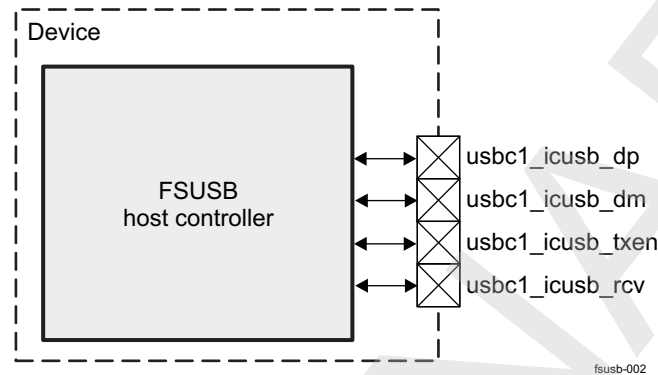

- USB 2.0 low-speed (1.5 Mbps) and full-speed (12 Mbps) operations
- Single port
- USB port signal pins interface:
  - Only supports the 2-/4-pin (bidirectional) mode
- Slave interface (L4) supporting:
  - 32-bit data bus width
  - 32-bit access
  - 32-bit address bus width
  - Wireless network portability (WNP)
  - Burst is not supported
- Master interface (L3) supporting:
  - 32-bit data bus width
  - 8-/32-bit access
  - 32-bit address bus width
  - Write nonposted (WRPN) interconnect transaction

### 23.13.2 FSUSB Host Controller Environment

This section describes the FSUSB host controller application fields from an environment point of view (external connections). It discusses FSUSB host controller connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

Figure 23-264 shows the output pins of the FSUSB host controller.

**Figure 23-264. Overview of FSUSB Host Controller Environment**

#### 23.13.2.1 FSUSB Host Controller Functional Interfaces Description

Table 23-1235 and Table 23-1236 list the input/output (I/O) signals.

**Table 23-1235. Pin List for FS USB-Host (USB-Interchip Mode)**

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
usbc1_icusb_dp	I/O	Interchip FSUSB host controller D plus	Unknown
usbc1_icusb_dm	I/O	Interchip FSUSB host controller D minus	Unknown

<sup>(1)</sup> I = Input, O = Output

**Table 23-1236. 4-Pin Mode Delivered on Pin (for External Transceiver Connection)**

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
usbc1_icusb_dp	I/O	FSUSB host controller D plus	Unknown
usbc1_icusb_dm	I/O	FSUSB host controller D minus	Unknown
usbc1_icusb_txen	O	FSUSB host controller transmit enable	Unknown
usbc1_icusb_rcv	I	FSUSB host controller receive	Unknown

<sup>(1)</sup> I = Input, O = Output

### 23.13.3 FSUSB Host Controller Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 23-265 shows the integration of the FSUSB host controller in the device.

Figure 23-265. FSUSB Host Controller Integration

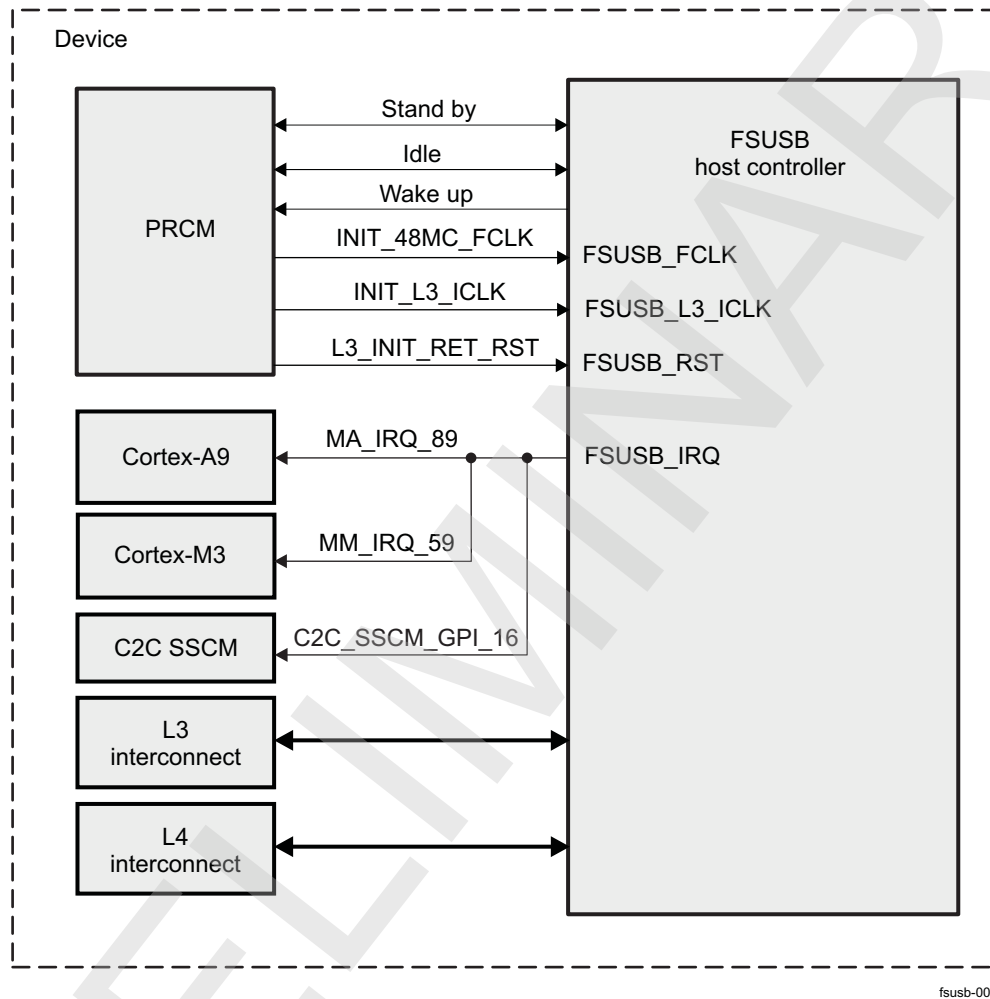

Table 23-1237 through Table 23-1239 summarize the integration of the module in the device.

Table 23-1237. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
FSUSB host controller	PD_L3_INIT	L3 L4_CFG

Table 23-1238. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
FSUSB host controller	FSUSB_FCLK	INIT_48MC_FCLK	PRCM	Functional clock (see Section 3.6.9, CD_L3_INIT Clock Domain in Chapter 3, Power, Reset, and Clock Management).

**Table 23-1238. Clocks and Resets (continued)**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
	FSUSB_L3_ICLK	INIT_L3_ICLK	PRCM	L3 interconnect clock for the L3 master port interface (see <a href="#">Section 3.6.9, CD_L3_INIT Clock Domain</a> in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
	FSUSB_L4_ICLK	INIT_L4_ICLK	PRCM	L4 interconnect-enable signal for the slave interface on L4 (see <a href="#">Section 3.6.3.2, CM Clock Source</a> in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
Resets				
FSUSB host controller	FSUSB_RST	L3_INIT_RET_RST	PRCM	This signal resets the FSUSB host controller module.

**Table 23-1239. Hardware Requests**

Interrupt Requests					
Module Instance		Source Signal Name	Destination Signal Name	Destination	Description
FSUSB controller	host	FSUSB_IRQ	MA_IRQ_89	Cortex-A9 INTC	Destination is Cortex-A9 interrupt controller (INTC)
		FSUSB_IRQ	MM_IRQ_59	Cortex-M3 INTC	Destination is Cortex-M3 INTC
		FSUSB_IRQ	C2C_SSCM_GPI_16	C2C INTC	Destination is C2C INTC

**NOTE:** For interrupt source information, see [Section 23.13.5.1.2, Interrupt Requests](#).

## 23.13.4 FSUSB Host Controller Functional Description

### 23.13.4.1 Resets

The different software reset functions of the FSUSB host controller are controlled by the following register bits:

- **HCOCPYSYS[1] SOFT\_RESET** bit: Writing 0x1 to this bit resets the entire module, except IDLE, STANDBY, and DISCONNECT logic. The bit value of 0x1 remains until the reset completes. When the software reset completes, the SOFT\_RESET bit is automatically set to 0x0.
- **HCCOMMANDSTATUS[0] HCR** bit: Writing 0x1 resets most of the open host controller interface (OHCI) registers of the FSUSB host controller. It is useful for error handling only. OHCI register accesses must not be attempted until a read of this register returns 0x0.

### 23.13.4.2 Power Management

#### 23.13.4.2.1 Features

The power management module has the following features:

- The FSUSB host controller has one instance of IDLE and standby interface.
- There are separate disconnect interfaces for master and slave ports.
- The PRCM module uses IDLE protocol to put the FSUSB host controller asynchronous into idle mode.
- The FSUSB host controller uses standby protocol for USB suspend event.
- Clock gating is done externally for IDLE and standby protocol.
- The IDLE and STANDBY interfaces are synchronous to the PRCM clock.

#### 23.13.4.2.2 IDLE Protocol

The IDLE protocol has the following features:

- There is one IDLE protocol for the FSUSB host controller.
- The **HCOCPYSYS[3:2] IDLE\_MODE** bit field controls the way USBFSHOST handles the IDLE protocol.
- The FSUSB host controller WakeupEnable mode is enabled by setting the **HCOCPYSYS[3:2] IDLE\_MODE** bit field to 0x11.
- Wakeup is generated asynchronously in the FSUSB host controller. To detect the USB remote wakeup, the FSUSB host controller should always be powered up (that is, the clocks can be off, but the power is needed for a wake-up detection to work).
- The FSUSB host controller interface asserts wakeup from suspend when the wake-up conditions occur (such as remote signaling on port, device connect/disconnect) and the FSUSB host controller is in idle mode. The FSUSB host controller interface deasserts the wake-up signal when the PRCM module has serviced the event (usually at completion of a resume sequence on the USB) and IDLE request is 0.
- The FSUSB host controller interface acknowledges and goes into IDLE only if the host controller is in suspend mode, or if force-idle mode is enabled.

Table 23-1240 lists the FSUSB host controller idle mode settings.

**Table 23-1240. FSUSB Host Controller Idle Mode Settings**

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The high-speed USB host controller unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations.
0x1	Not supported (no-idle)	
0x2	Smart-idle	The high-speed USB host controller acknowledges the IDLE request, basing its decision on its internal activity. Namely, the acknowledged signal is asserted only when all pending transactions, IRQs, or DMA requests are treated.
0x3	Smart-idle wakeup	The high-speed USB host controller enters smart mode with asynchronous wakeup enabled.

### 23.13.4.2.3 Standby Protocol

The Standby protocol is associated with FSUSB host controller suspend. Standby assertion is linked with Suspend, and Wakeup assertion is linked with remote wakeup. When the application wants to resume the USB, the power manager must initiate the wakeup using the Standby protocol.

- There is one Standby protocol for the FSUSB host controller.
- The `HCOCPSYS[5:4]` STANDBY\_MODE bit field controls the way USBFSHOST handles the Standby protocol.
- The FSUSB host controller wakes up with standby, and stays in standby until the host core becomes functional.

Table 23-1241 lists the STANDBY\_MODE settings for the FSUSB host controller.

**Table 23-1241. FSUSB Host Controller STANDBY\_MODE Settings**

MIDLEMODE Value	Selected Mode	Description
0x0	Force-standby	The high-speed USB host controller enters standby mode unconditionally (Mstandby is asserted unconditionally).
0x1	Not supported (no-standby)	
0x2	Smart-standby	The high-speed USB host controller is ready to enter standby mode when there is no more activity on the USB master interface of the interconnect.
0x3	Smart-standby wakeup	The high-speed USB host controller enters smart mode with asynchronous wakeup enabled.

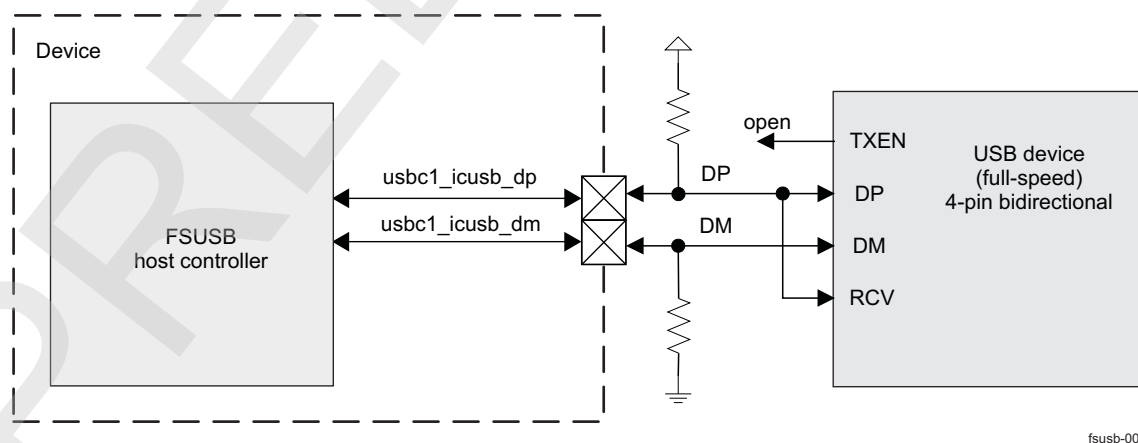

### 23.13.4.3 FSUSB Host Controller Bidirectional Interface Modes

Bidirectional SIM interface modes are implemented using existing bidirectional modes. Their goal is to reduce pin count with respect to 6-/5-pin modes.

Pullup/pulldown resistors on the bidirectional lines are compulsory, because the lines are not constantly driven from one side or the other of the interface. In this case, the pullup on one of the two lines triggers the connect signal from the device to the host. The pullup can be controlled (by the USB device side) or hardwired. In the first case, the USB host sees only the external device if the pullup is active; in the second case, the USB host sees the device as soon as software enables the port in question.

The device supports the 2-pin bidirectional SIM Interface mode with DP/DM encoding. Figure 23-266 shows a USB port using DP/DM encoding.

**Figure 23-266. 2-Pin Bidirectional Interface Using DP/DM Encoding With a Standard 4-Pin Bidirectional USB Device**

A specific 2-pin USB device can also be implemented with just the two bidirectional pins. Figure 23-267 shows an example in DP/DM encoding with built-in pullup/pulldown resistors.

**Figure 23-267. 2-Pin Bidirectional Interface Using DP/DM Encoding With a Specific 2-Pin Bidirectional USB Device**

### 23.13.5 FSUSB Host Controller Basic Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the FSUSB host controller.

#### 23.13.5.1 Global Initialization

##### 23.13.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the FSUSB host controller is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the FSUSB host controller.

Table 23-1242 describes the global initialization of the surrounding modules.

**Table 23-1242. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	All clocks must be enabled (see Table 23-1238). See Section 3.6.3.2, CM Clock Source in Chapter 3, Power, Reset and Clock Management.
Cortex-A9 MPU INTC or Cortex-M3 MPU INTC	The Cortex-A9 MPU or Cortex-M3 MPU INTC must be configured to enable the interrupt request generation to the Cortex-A9 MPU or Cortex-M3 MPU subsystem when interrupt requests are generated by the FSUSB host controller. See the respective functional description in Chapter 17, Interrupt Controllers, for the MPUs.
Interconnect (L3 and L4)	For more information, see Section 13.2, L3 Interconnect, and Section 13.3, L4 Interconnect.

**NOTE:** This module requires an active functional clock for L4 access to function.

##### 23.13.5.1.2 FSUSB Host Controller Global Initialization

This procedure initializes the FSUSB host controller after a power-on or software reset (see Table 23-1243).

**Table 23-1243. High-Speed Multiport USB Host Subsystem Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Perform a software reset on the FSUSB host controller module, except for IDLE, STANDBY, and DISCONNECT logics.	HCOCPSYS[1] SOFT_RESET	0x1

**Table 23-1243. High-Speed Multiport USB Host Subsystem Global Initialization (continued)**

Step	Register/Bit Field/Programming Model	Value
Wait until reset is finished.	HCOCPSYS[1] SOFT_RESET	0x0
Enable IRQ event for the FSUSB host controller.	HCINTERRUPTENABLE[31] MIE	0x1
Enable IRQ event for each function of the FSUSB host controller.	HCINTERRUPTENABLE[6:0] xxx	0x1

## MMC/SD/SDIO

This chapter describes the features and functions of the multimedia card/SD card (MMC/SD/SDIO) interface of the device.

Topic	Page
24.1 MMC/SD/SDIO Overview .....	4958
24.2 MMC/SD/SDIO Environment .....	4964
24.3 MMC/SD/SDIO Integration .....	4972
24.4 MMC/SD/SDIO Functional Description .....	4975
24.5 MMC/SD/SDIO Programming Guide .....	5004
24.6 MMC/SD/SDIO Register Manual .....	5030

## 24.1 MMC/SD/SDIO Overview

The multimedia card high-speed/SD/SDIO (MMC/SD/SDIO) host controller provides an interface between a local host (LH) such as a microprocessor unit (MPU) or digital signal processor (DSP) and either MMC, SD memory cards, or SDIO cards and handles MMC/SD/SDIO transactions with minimal LH intervention.

Optionally, the controller is connected to the L3 interconnect to have a direct access to system memory. It also supports two DMA slave channels or a DMA master access (in this case, slave DMA channels are deactivated) depending on its integration. These controllers are embedded MMC/SD (eMMC/SD) controllers.

The application interface manages transaction semantics. The MMC/SD/SDIO host controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRC), start/end bit, and checking for syntactical correctness.

The application interface can send every MMC/SD/SDIO command and poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The MMC/SD/SDIO host controller also supports two DMA channels.

There are five MMC/SD/SDIO host controllers inside the device:

[Figure 24-1](#) gives an overview of the MMC/SD/SDIO1 controller instance (eMMC/SD).

[Figure 24-2](#) gives an overview of the MMC/SD/SDIO2 controller instance (eMMC/SD).

[Figure 24-3](#) gives an overview of the MMC/SD/SDIO3 through MMC/SD/SDIO5 controller instances.

Figure 24-1. MMC/SD/SDIO1 Overview (where i = 1)

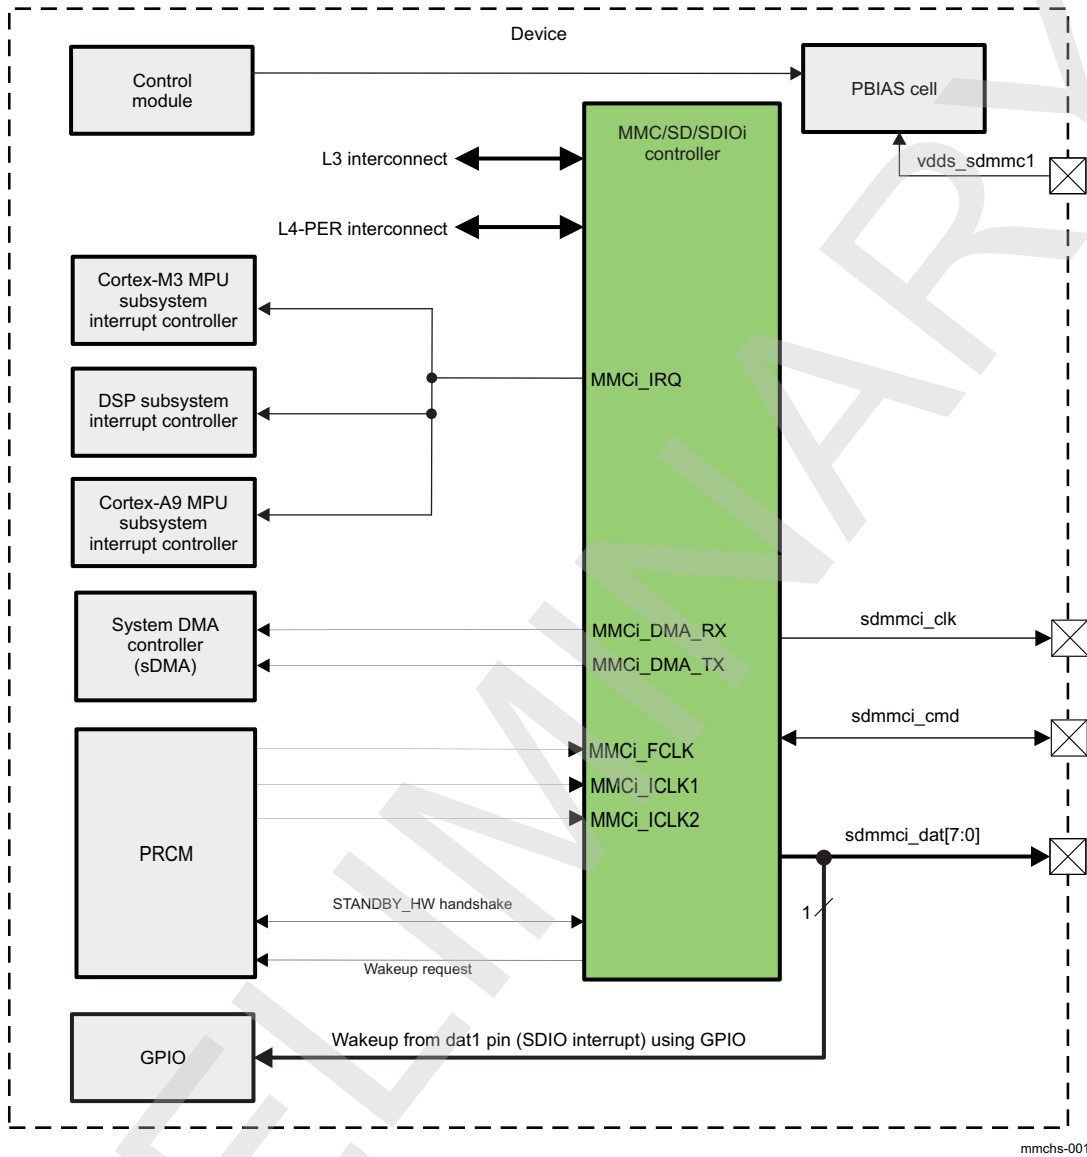

Figure 24-2. MMC/SD/SDIO2 Overview (where i = 2)

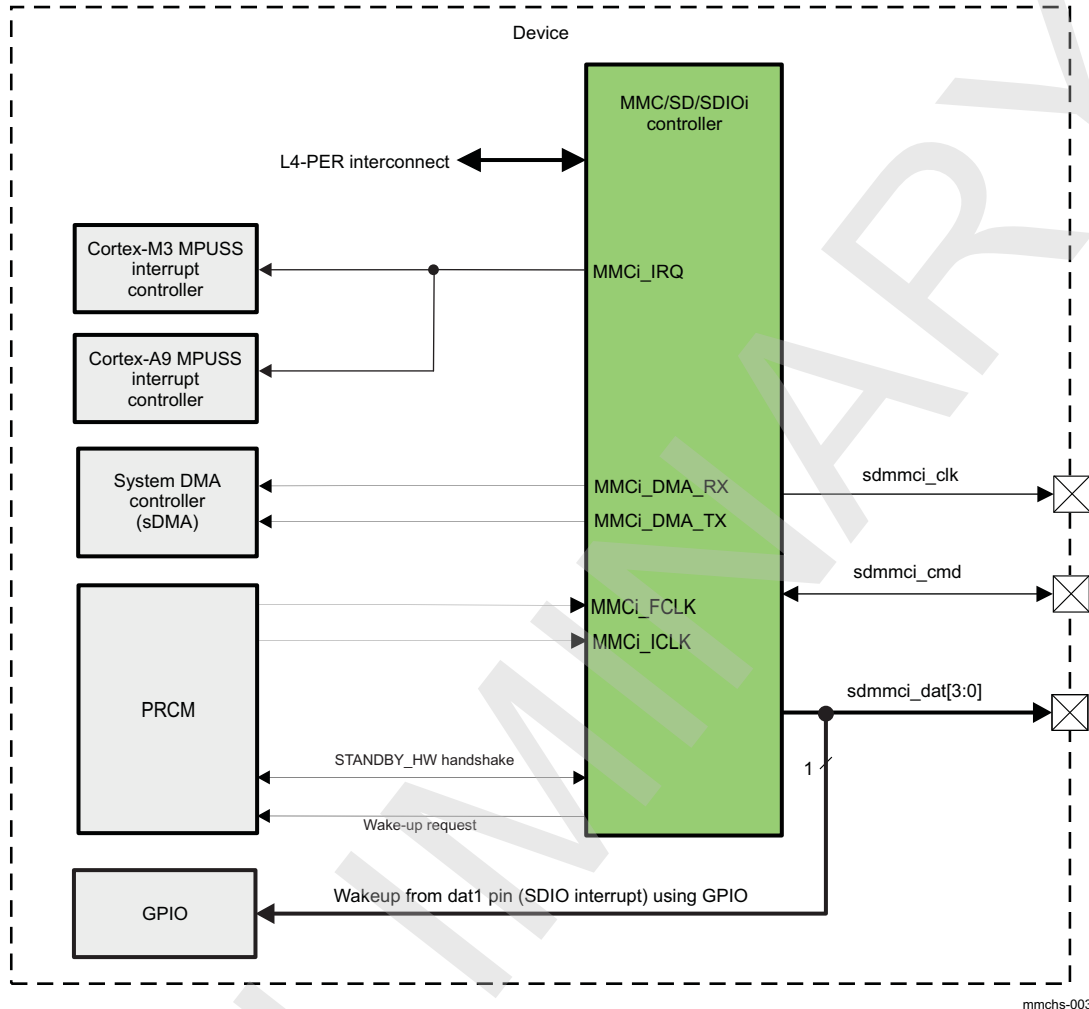

Figure 24-3. MMC/SD/SDIO3 Through MMC/SD/SDIO5 Overview (where i = 3, 4, or 5)

### 24.1.1 MMC/SD/SDIO Features

This section describes the features supplied by the MMC/SD/SDIO module.

Compliance with standards:

- Full compliance with MMC command/response sets as defined in the *Multimedia Card System Specification*, v4.4, including high-capacity (size > 2GB) cards HC MMC
- Full compliance with SD command/response sets as defined in the *SD Memory Card Specifications*, v3.0, including high-capacity SDHC cards up to 32GB
- Full compliance with SDIO command/response sets and interrupt/read-wait mode as defined in the *SDIO Card Specification, Part E1*, v2.00
- Compliance with sets as defined in the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v2.00
- Full compliance with MMC bus testing procedure as defined in the *Multimedia Card System Specification*, v4.4
- Full compliance with CE-ATA command/response sets as defined in the *CE-ATA Standard Specification*
- Full compliance with ATA for MMCA specification
- Support command completion signal (CCS) and command completion signal disable (CCSD) management as specified in the *CE-ATA Standard Specification*

Main features of the MMC/SD/SDIO host controller:

- Flexible architecture allowing support for new command structure
- Support:
  - 1- or 4-bit transfer mode specifications for SD and SDIO cards
  - 1-, 4-, or 8-bit transfer mode specifications for MMC cards
- Built-in buffer for read or write (up to 4096 bytes in single-buffering, 2048 bytes in double-buffering)
- 32-bit-wide access bus to maximize bus throughput
- Single interrupt line for multiple interrupt source events
- Two slave DMA channels (one for TX, one for RX)
- Designed for low power
- Programmable clock generation
- Support SDIO read wait and suspend/resume functions
- Support stop at block gap
- Support MMC4.4 JC 64.1 boot mode operations
- Support dual data rate transfers (DDR mode) as specified in *JEDEC JC64 Item #18.00 Bus Performance Proposal (February 2008)*
- Support SDA 2.0 Part A2 programming model

Optional features (depending on module integration):

- Master interface (level 3 [L3] interconnect)
- One master DMA (32-bit ADMA2), replacing the two slave DMA channels
- Retention mode is supported
- Support SDA 2.0 Part A2 DMA feature (ADMA2)

Supported data rates:

- Up to 768 Mbps (96 Mbps) in MMC mode, 8-bit DDR data transfer, 48-MHz card clock when functional clock is 48 MHz
- Up to 384 Mbps (48 Mbps) MMC mode, 8-bit SDR data transfer, 48-MHz card clock when functional clock is 48 MHz
- Up to 192 Mbps (24 Mbps) in high-speed SD mode 4-bit data transfer
- Up to 24 Mbps (3 Mbps) in default SD mode 1-bit data transfer

Supported MMC clock frequencies:

- Up to 64 MHz in standard mode and up to 48 MHz in DDR mode
- Up to 96 MHz in single data rate (SDR) mode for embedded devices

Known limitations:

- No built-in hardware support for error correction codes (ECC). For information about ECC, see the *Multimedia Card System Specification, v4.4*, and the *SD Memory Card Specifications, v3.0*.
- The maximum block size defined in the *SD Memory Card Specifications, v3.0*, which the host driver can read and write to the buffer in the host controller, is 2048 bytes. MMC supports a maximum block size of 1024 bytes. Up to 512 byte transfers, the buffer in MMC is considered as a double-buffering with ping-pong management; half of the buffer can be written while the other half is read. For 512 to 1024 byte transfers, the entire buffer is dedicated to the transfer (read only or write only).
- SPI transfers are not supported.
- Module does not support card insertion/removal sensing with pullup resistor on sdmmc\_i\_dat3 bus line, as specified in the *SD Memory Card Specifications – Part 1 Physical Layer Specification (SD Group, May 2006)*.

The differences between the MMC/SD/SDIO host controllers and a standard SD host controller defined by the *SD Card Specification, Part A2, SD Host Controller Standard Specification, v2.00* are:

- The MMC/SD/SDIO host controllers support MMC cards.
- The clock divider in the MMC/SD/SDIO host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications, v2.0*. The MMC/SD/SDIO host controller supports odd and even clock ratio.

- The MMC/SD/SDIO host controller supports configurable busy time-out.
- sDMA and ADMA2 64-bit modes are not supported.
- No external LED control

---

**NOTE:** Only even ratios are supported in DDR mode

---

## 24.2 MMC/SD/SDIO Environment

One MMC/SD/SDIO host controller can support one MMC memory card, one SD memory card, or one SDIO card.

Other combinations (for example, two SD cards, one MMC card, and one SD card) are not supported through a single controller.

- The MMC/SD/SDIO1 controller integrates an internal transceiver that allows a direct connection to the MMC/SD/SDIO card (1.8 V and 3 V), without external transceiver. It is connected to the level 3 (L3) interconnect (internal DMA enabled) and supports 1-, 4-, and 8-bit data transfers.
- The MMC/SD/SDIO2 controller allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (JC64, for example). The module is connected to the L3 interconnect (internal DMA enabled) and supports 1-, 4-, and 8-bit data transfers. The second instance also supports an external transceiver and provides direction signals for data and command. Using an external transceiver device precludes 8-bit transfer mode.
- The MMC/SD/SDIO3, MMC/SD/SDIO4, and MMC/SD/SDIO5 controllers allow connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (wireless LAN, for example). The modules are connected to the L4 interconnect (internal DMA enabled) and support 1- and 4-bit data transfers.

### 24.2.1 MMC/SD/SDIO Functional Modes

#### 24.2.1.1 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card

Figure 24-4 shows the MMC/SD/SDIO<sub>i</sub> host controller (where *i* = 1 through 5) connected to an MMC, an SD, or an SDIO card and its related external connections.

**Figure 24-4. MMC/SD/SDIO<sub>i</sub> Controller Connected to an MMC, an SD, or an SDIO Card Without External Transceiver (where *i* = 1 through 5)**

mmchs-004

**NOTE:** Modules MMC/SD/SDIO1 and MMC/SD/SDIO2 support data transfers on 8 bits (and thus handle data on signals `sdmmc_i_dat[7:0]`)

Table 24-1 describes the MMC/SD/SDIO<sub>i</sub> inputs and outputs.

**Table 24-1. MMC/SD/SDIOi I/O Description Without External Transceiver (where i = 1 through 5)**

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
sdmmc_clk	O	External clock for MMC/SD/SDIO card <sup>(2)</sup>	0
sdmmc_cmd	I/O	Command signal	HiZ <sup>(3)</sup>
sdmmc_dat[3:0]	I/O	Data signals	HiZ <sup>(3)</sup>
sdmmc_dat[7:4]	I/O	Data signals (only for modules MMC/SD/SDIO1 and MMC/SD/SDIO2)	HiZ <sup>(3)</sup>

<sup>(1)</sup> I = Input; O = Output.

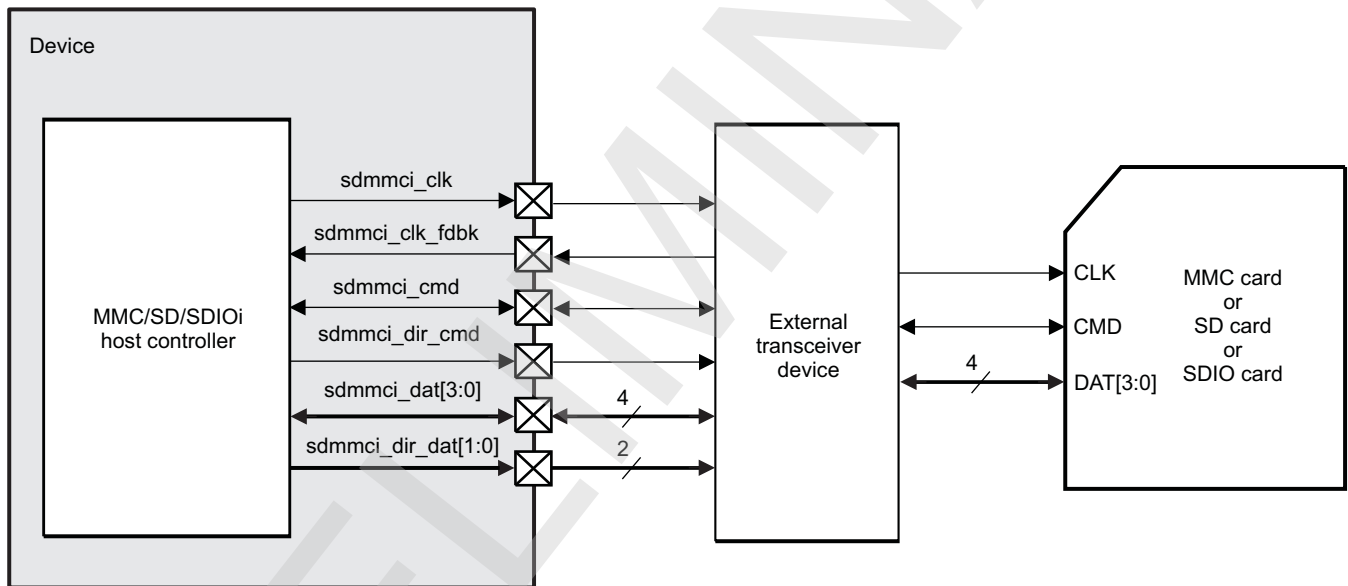

<sup>(2)</sup> This output signal is also used as retiming input.

<sup>(3)</sup> Initialized as input upon reset

**24.2.1.2 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card Through an External Transceiver Device**

Figure 24-5 shows the MMC/SD/SDIOi (where i = 2) host controller connected to an MMC, an SD, or an SDIO card and its related external connections.

**Figure 24-5. MMC/SD/SDIOi Controller Connected to an MMC, an SD, or an SDIO Card with External Transceiver (where i = 2)**

mmchs-005

Table 24-2 describes the MMC/SD/SDIOi inputs and outputs.

**Table 24-2. MMC/SD/SDIOi I/O Description With External Transceiver (where i = 2)**

Signal Name	I/O	Description	Reset Value
sdmmc_clk	O	External clock for MMC/SD/SDIO card	0
sdmmc_clk_fdbk	I	Input clock from MMC/SD/SDIO card	0
sdmmc_cmd	I/O	Command signal	HiZ <sup>(1)</sup>
sdmmc_dir_cmd	O	Direction control for mmc2_cmd signal when an external transceiver is used (high when transmit, low when receive)	0
sdmmc_dat[3:0]	I/O	Data signals	HiZ <sup>(1)</sup>
sdmmc_dir_dat0	O	Direction control for mmc2_dat0 signal when an external transceiver is used (high when transmit, low when receive)	0

<sup>(1)</sup> (1) Initialized as input upon reset

**Table 24-2. MMC/SD/SDIOi I/O Description With External Transceiver (where i = 2) (continued)**

Signal Name	I/O	Description	Reset Value
sdmmc_dir_dat1	O	Direction control for mmc2_dat1 signal when an external transceiver is used (high when transmit, low when receive)	0

**NOTE:** There is no signal for controlling individually the sdmmc\_dir\_dat2 and sdmmc\_dir\_dat3 direction (sdmmc\_dir\_dat2 and sdmmc\_dir\_dat3 are not delivered), this may limit the use of this interface with the SDIO card requesting the wait feature on the sdmmc\_dir\_dat2 line.

## 24.2.2 Protocol and Data Format

The bus protocol between the MMC/SD/SDIOi host controller and the card is message-based. Each message is represented by one of the following parts:

**Command:** A command starts an operation. The command is transferred serially from the MMC/SD/SDIO host controller to the card on the sdmmc\_cmd line.

**Response:** A response is an answer to a command. The response is sent from the card to the MMC/SD/SDIO host controller. It is transferred serially on the sdmmc\_cmd line.

**Data:** Data are transferred from the MMC/SD/SDIOi host controller to the card or from a card to the MMC/SD/SDIO host controller using the data lines.

**Busy:** The sdmmc\_dat0 signal is maintained low by the card as far as it is programming the data received.

**CRC status:** The CRC result is sent by the card through the sdmmc\_dat0 line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on sdmmc\_dat0. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on sdmmc\_dat0 and starts the data programming procedure.

### 24.2.2.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented).

For information about commands and programming sequences supported by the MMC, SD, and SDIO cards, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification (Part E1)*.

Figure 24-6 and Figure 24-7 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the sdmmc\_cmd line.

#### CAUTION

Stream commands are supported only by MMC cards.

**Figure 24-6. Sequential Read Operation (MMC Cards Only)**

**Figure 24-7. Sequential Write Operation (MMC Cards Only)**

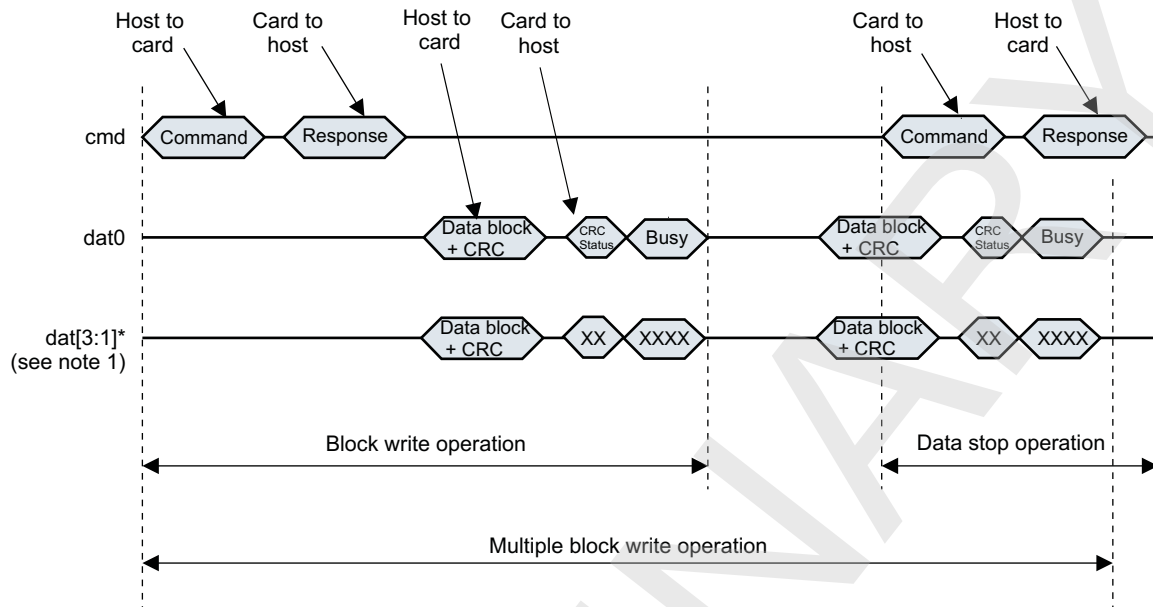

Figure 24-8 and Figure 24-9 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the sdmmc\_i\_cmd line. These operations are available for all kinds of cards.

**Figure 24-8. Multiple Block Read Operation**

**Figure 24-9. Multiple Block Write Operation With Card Busy Signal**

mmchs-009

**NOTE:**

1. The card busy signal is not always generated by the card; the previous examples show a particular case.
2. Software must perform a software reset (set MMCi.MMCHS\_SYSCTL[26] SRD bit to 0x1) after a data time-out to ensure sdmmc\_i\_clk is stopped.
3. For multiblock transfer, and especially for MMC cards, a transfer can be aborted without using a stop command. If a CMD23 is used before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMC card supports this feature).

**24.2.2.2 Data Format****Coding Scheme for Command Token**

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see [Figure 24-10](#)).

**Figure 24-10. Command Token Format**

mmchs-010

**Coding Scheme for Response Token**

Response tokens always start with 0 and end with 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5, R6, R7 [for SDIO])

and the content is protected by 7-bit CRC checksum (see [Figure 24-11](#) and [Figure 24-12](#)). Depending on the type of commands sent to the card, the `MMCHS_CMD` register must be configured differently to avoid false CRC or index errors to be flagged on command response (see [Table 24-3](#)). For more information about response types, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification*.

**Figure 24-11. Response Token Format (R1, R3, R4, R5, R6, R7)**

**Figure 24-12. Response Token Format (R2)**

**Table 24-3. Relationship Between Configuration and Name of Response Type**

Response Type MMCI.MMCHS_CMD[17:16] RSP_TYPE	Index Check Enable MMCI.MMCHS_CMD[20] CICE	CRC Check Enable MMCI.MMCHS_CMD[19] CCCE	Name of Response Type
00	0	0	No response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5, R7
11	1	1	R1b, R5b

**Coding Scheme for Data Token**

Data tokens always start with 0 and end with 1 (see [Figure 24-13](#) through [Figure 24-15](#)).

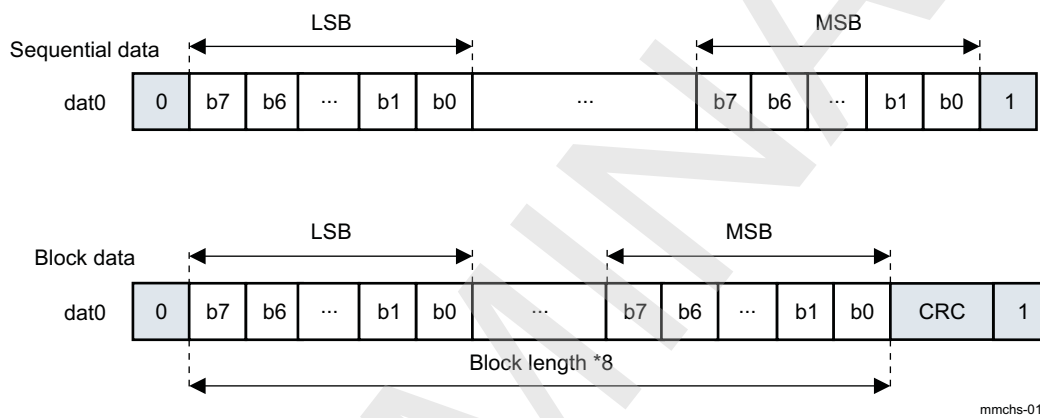

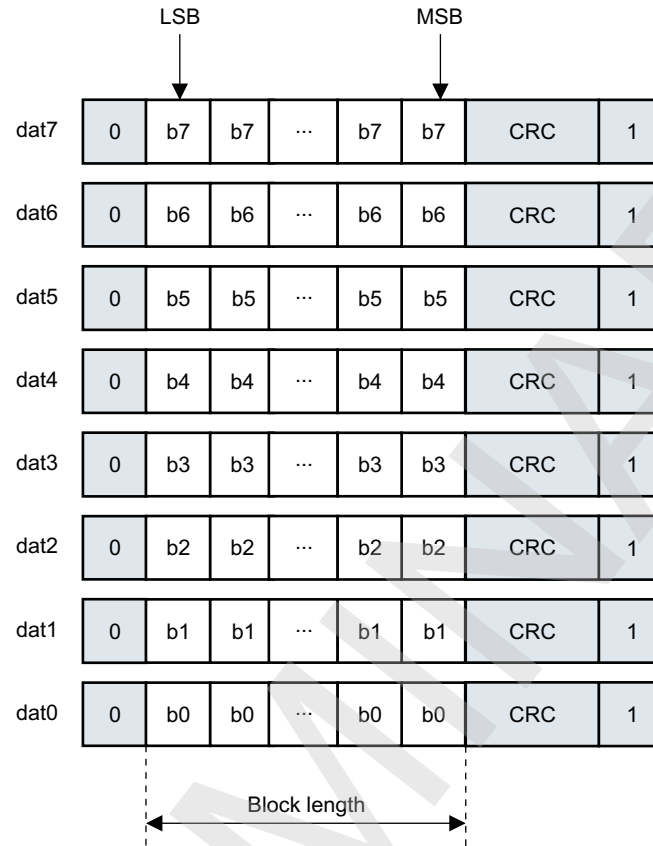

**Figure 24-13. Data Token Format for 1-Bit Transfers****Figure 24-14. Data Token Format for 4-Bit Transfers**

Figure 24-15. Data Token Format for 8-Bit Transfers

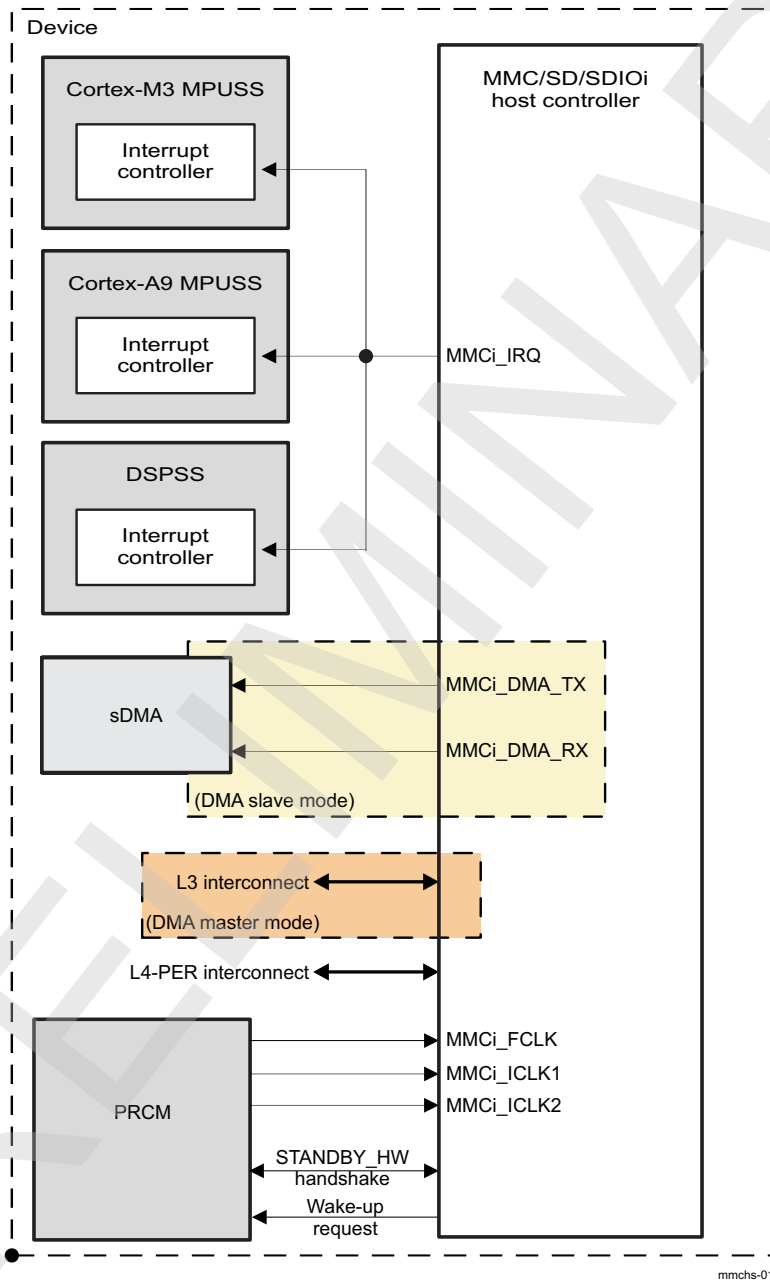

mmchs-015

### 24.3 MMC/SD/SDIO Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 24-16 shows the MMC/SD/SDIO integration.

**Figure 24-16. MMC/SD/SDIO Controllers Integration**

**NOTE:** For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 24-4 through Table 24-6 summarize the integration of the module in the device.

**Table 24-4. Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
HSMMC1	PD_L3_INIT	L3 L4_PER
HSMMC2	PD_L3_INIT	L3 L4_PER
HSMMC3	PD_L4_PER	L4_PER
HSMMC4	PD_L4_PER	L4_PER
HSMMC5	PD_L4_PER	L4_PER

**Table 24-5. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
HSMMC1	MMC1_FCLK	MMC1_FCLK	PRCM	MMC1 function clock
	MMC1_ICLK2	INIT_L4_ICLK	PRCM	MMC1 interface clock
	MMC1_ICLK1	INIT_L3_ICLK	PRCM	MMC1 interface clock
HSMMC2	MMC2_FCLK	MMC2_FCLK	PRCM	MMC2 function clock
	MMC2_ICLK2	INIT_L4_ICLK	PRCM	MMC2 interface clock
	MMC2_ICLK1	INIT_L3_ICLK	PRCM	MMC2 interface clock
HSMMC3	MMC3_ICLK	PER_L4_ICLK	PRCM	MMC3 interface clock
	MMC3_FCLK	PER_48M_FCLK	PRCM	MMC3 function clock
HSMMC4	MMC4_ICLK	PER_L4_ICLK	PRCM	MMC4 interface clock
	MMC4_FCLK	PER_48M_FCLK	PRCM	MMC4 function clock
HSMMC5	MMC5_ICLK	PER_L4_ICLK	PRCM	MMC5 interface clock
	MMC5_FCLK	PER_48M_FCLK	PRCM	MMC5 function clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
HSMMC1	MMC1_RST	L3_INIT_RET_RST	PRCM	L3 reset to MMC1
HSMMC2	MMC2_RST	L3_INIT_RET_RST	PRCM	L3 reset to MMC2
HSMMC3	MMC3_RST	L4_PER_RST	PRCM	L4 reset to MMC3
HSMMC4	MMC4_RST	L4_PER_RST	PRCM	L4 reset to MMC4
HSMMC5	MMC5_RST	L4_PER_RST	PRCM	L4 reset to MMC5

**Table 24-6. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
HSMMC1	MMC1_IRQ	MM_IRQ_50	Cortex-M3 INTC	MMC1 interrupt to Cortex-M3
	MMC1_IRQ	D_IRQ_16	DSP INTC	MMC1 interrupt to DSP
	MMC1_IRQ	MA_IRQ_83	Cortex-A9 INTC	MMC1 interrupt to Cortex-A9
HSMMC2	MMC2_IRQ	MM_IRQ_51	Cortex-M3 INTC	MMC2 interrupt to Cortex-M3
	MMC2_IRQ	D_IRQ_17	DSP INTC	MMC2 interrupt to DSP
	MMC2_IRQ	MA_IRQ_86	Cortex-A9 INTC	MMC2 interrupt to Cortex-A9
HSMMC3	MMC3_IRQ	MM_IRQ_52	Cortex-M3 INTC	MMC3 interrupt to Cortex-M3
	MMC3_IRQ	MA_IRQ_94	Cortex-A9 INTC	MMC3 interrupt to Cortex-A9

	MMC4_IRQ	MA_IRQ_96	Cortex-A9 INTC	MMC4 interrupt to Cortex-A9
HSMMC5	MMC5_IRQ	MM_IRQ_54	Cortex-M3 INTC	MMC5 interrupt to Cortex-M3
	MMC5_IRQ	MA_IRQ_59	Cortex-A9 INTC	MMC5 interrupt to Cortex-A9
DMA Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
HSMMC1	MMC1_DMA_TX	S_DMA_60	sDMA	MMC1 DMA TX
	MMC1_DMA_RX	S_DMA_61	sDMA	MMC1 DMA RX
HSMMC2	MMC2_DMA_TX	S_DMA_46	sDMA	MMC2 DMA TX
	MMC2_DMA_RX	S_DMA_47	sDMA	MMC2 DMA RX
HSMMC3	MMC3_DMA_TX	S_DMA_76	sDMA	MMC3 DMA TX
	MMC3_DMA_RX	S_DMA_77	sDMA	MMC3 DMA RX
HSMMC4	MMC4_DMA_TX	S_DMA_56	sDMA	MMC4 DMA TX
	MMC4_DMA_RX	S_DMA_57	sDMA	MMC4 DMA RX
HSMMC5	MMC5_DMA_TX	S_DMA_58	sDMA	MMC5 DMA TX
	MMC5_DMA_RX	S_DMA_59	sDMA	MMC5 DMA RX

**NOTE:**

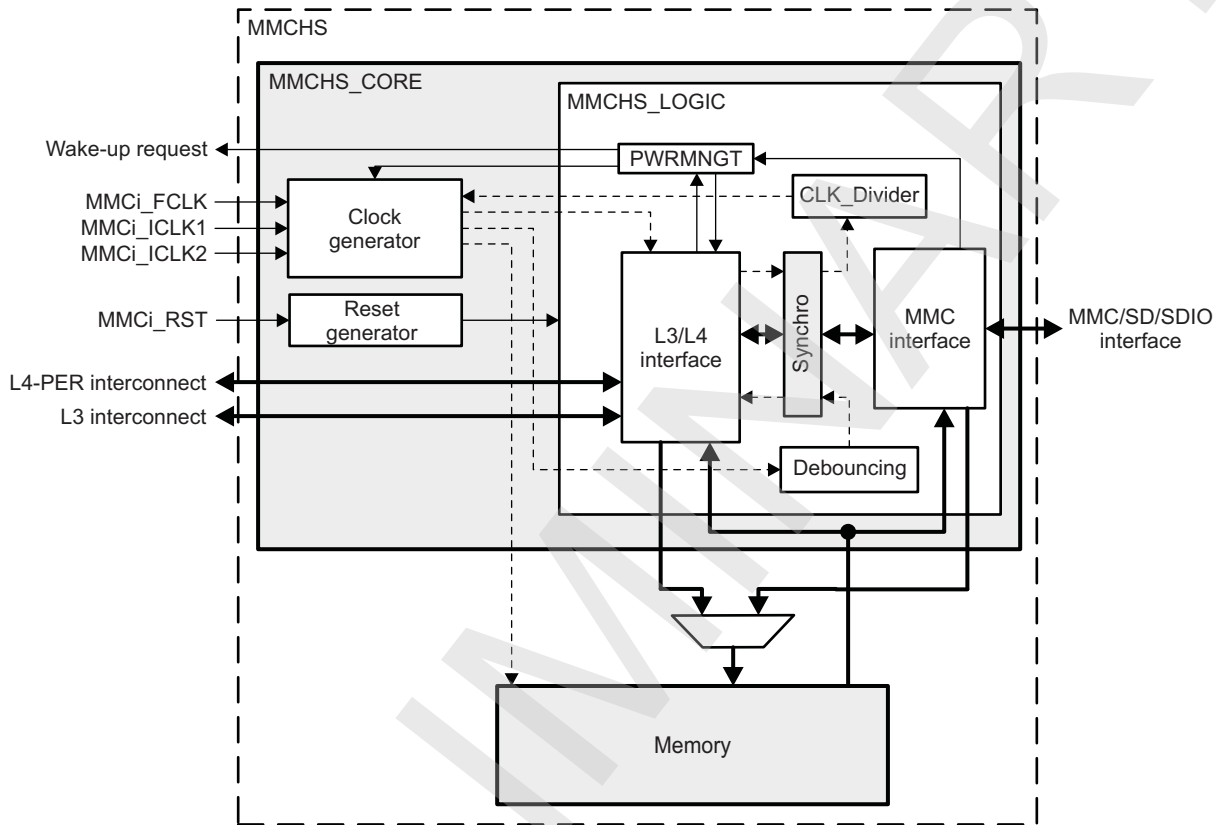

- For a description of the interrupt source, see [Section 24.4.4, Interrupt Requests](#).
- For a description of the DMA source, see [Section 24.4.5, DMA Requests](#).

## 24.4 MMC/SD/SDIO Functional Description

### 24.4.1 Block Diagram

Figure 24-17 is a block diagram of the MMC/SD/SDIOi host controller.

Figure 24-17. MMC/SD/SDIO Diagram

mmchs-017

### 24.4.2 Resets

#### 24.4.2.1 Hardware Reset

The module is reinitialized by the hardware (see Table 24-5 for more information about reset signals).

The MMCHS.MMCHS\_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a hardware reset.

**NOTE:** The functional clock (MMCi\_FCLK) and interface clock (MMCi\_ICLK) must be provided to the module to allow the RESETDONE status bit to be set.

The debounce clock (MMCi\_32K) must be active to reset the module correctly.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

#### 24.4.2.2 Software Reset

The module is reinitialized by software through the MMCHS.MMCHS\_SYSCONFIG[1] SOFTRESET bit. This bit has the same action on the module logic as the hardware signal (MMCi\_RST), with the following exceptions:

- Debounce logic

- MMCI.MMCHS\_PSTATE, MMCI.MMCHS\_CAPA, and MMCI.MMCHS\_CUR\_CAPA registers (see the corresponding register description)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by the hardware. The MMCI.MMCHS\_SYSCTL[24] SRA bit has the same action on the design as the SOFTRESET bit.

The MMCI.MMCHS\_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCI.MMCHS\_SYSCTL[26] SRD bit
- MMCI.MMCHS\_SYSCTL[25] SRC bit

These two reset bits are useful to reinitialize data or command processes, respectively, in case of line conflict. When set to 1, a reset process is automatically released when the reset completes:

- The MMCI.MMCHS\_SYSCTL[26] SRD bit resets all finite state-machines and status management that handle data transfers on the interface and functional sides.
- The MMCI.MMCHS\_SYSCTL[25] SRC bit resets all finite state-machines and status management that handle command transfers on the interface and functional sides.

### 24.4.3 Power Management

The MMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The MMC/SD/SDIO host controller is compliant with the handshake protocol of the PRCM module.

When the MMC/SD/SDIO power domain is off, the only way to wake up the power domain and different MMC/SD/SDIO clocks is to monitor the state of the sdmmci\_dat1 input pin through a different GPIO line for each MMC/SD/SDIO interface (for more information, see [Section 25.1, GPIO Overview](#), in [Chapter 25, GPIO](#)).

#### Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The MMCI.MMCHS\_SYSCONFIG[0] AUTOIDLE bit is set to 1.
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L4 interconnect.
- A wake-up event occurs (an interrupt from an SDIO card).
- A transaction on the MMC/SD/SIO interface starts.

Then the MMC/SD/SDIO host controller enters into low-power state (MMCI\_ICLK clock autogated) even if the MMCI.MMCHS\_SYSCONFIG[0] AUTOIDLE bit is set to 0.

The functional clock is internally switched off and only interconnect read and write accesses are allowed.

#### Idle Mode

The MMCI\_ICLK and MMCI\_FCLK clocks provided to MMC/SD/SDIO are switched off upon a PRCM module request. They are switched back upon module request.

The MMC/SD/SDIO host controller complies with the handshaking protocol of the PRCM module:

- Idle request from the system power manager
- Idle acknowledgment from the MMC/SD/SDIO host controller
- Wake-up request from the MMC/SD/SDIO host controller

The idle acknowledgment varies according to the MMCI.MMCHS\_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0x0: Force-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request unconditionally.

- 0x1: No-idle mode. The MMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 0x2: Smart-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.
- 0x3: Smart-idle wake-up-capable mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state. However, the module may generate wake-up events when in IDLE state ( related to IRQ or DMA requests)

During the smart-idle mode period, the MMC/SD/SDIO host controller acknowledges that the MMCi\_ICLK and MMCi\_FCLK clocks may be switched off, regardless of the value set in the MMCi.MMCHS\_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

**Transition From Normal Mode to Smart-Idle Mode**

Smart-idle mode is enabled when the MMCi.MMCHS\_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x2 or 0x3.

The MMC/SD/SDIOi host controller goes into idle mode when the PRCM issues an idle request, according to its internal activity.

The MMC/SD/SDIO host controller acknowledges the idle request from the PRCM after ensuring the following:

- The current multi- or single-block transfer is complete.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on the sdmmc\_i\_dat1 signal.

As long as the MMC/SD/SDIOi controller does not acknowledge the idle request, if an event occurs, the MMC/SD/SDIOi host controller can still generate an interrupt or a DMA request. In this case, the module ignores the idle request from the PRCM module.

As soon as the MMC/SD/SDIOi controller acknowledges the idle request from the PRCM module:

- If smart-idle mode: The module does not assert any new interrupt or DMA request.
- If smart-idle wake-up-capable mode: The module may generate wake-up events related to an interrupt or DMA request.

**Wake-Up Event in Smart-Idle Mode**

The wake-up feature is enabled when the following enable wake-up bits are set:

- The MMCi.MMCHS\_SYSCONFIG[2] ENAWAKEUP bit is set to 0x1.
- The MMCi.MMCHS\_HCTL[24] IWE bit is set to 0x1.
- The MMCi.MMCHS\_IE[8] CIRQ\_ENABLE bit is set to 0x1.

The wakeup is generated only in smart-idle mode, when the module is in idle mode.

Table 24-7 lists the supported cases in smart-idle mode.

**Table 24-7. Smart-Idle Mode and Wake-Up Capabilities**

Mode	MMCi_ICLK clock	MMCi_FCLK clock	Wake-Up Event
Card interrupt	May be switched off <sup>(1)</sup>	May be switched off <sup>(1)</sup>	The module sends an asynchronous wake-up request on detection of a card interrupt on sdmmc_i_dat1 signal.

<sup>(1)</sup> The MMC/SD/SDIOi host controller assumes that both clocks may be switched off, regardless of the value set in the MMCi.MMCHS\_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

**Transition From Smart-Idle Mode to Normal Mode**

The MMC/SD/SDIO host controller detects the end of the idle period when the PRCM deasserts the idle request.

For the wake-up event, there is a corresponding interrupt status in the MMCi.MMCHS\_STAT register. The MMC/SD/SDIOi host controller operates the conversion between the wake-up and interrupt (or DMA request) upon exit from smart-idle mode, if the associated enable bit is set in the MMCi.MMCHS\_ISE register.

Interrupts and wake-up events have independent enable and disable controls, accessible through the MMCI.MMCHS\_HCTL and MMCI.MMCHS\_ISE registers. The overall consistency must be ensured by software.

The interrupt status register MMCI.MMCHS\_STAT is updated in the CIRQ bit with the event that caused the wakeup when the MMCI.MMCHS\_IE[8] CIRQ\_ENABLE associated bit is enabled.

Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The MMCI.MMCHS\_STAT register is updated and the status of the interrupt signal changes.)

When the idle request from the PRCM module is deasserted, the module switches back to normal mode. The module is fully operational.

### Force-Idle Mode

Force-idle mode is enabled when the MMCI.MMCHS\_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.

Force-idle mode is an idle mode in which the MMC/SD/SDIOi host controller responds unconditionally to the idle request from the PRCM module. Moreover, in this mode, the MMC/SD/SDIOi host controller unconditionally deasserts interrupts and DMA request lines asserted.

The transition from normal mode to force-idle mode does not affect the bits of the MMCI.MMCHS\_STAT register.

In force-idle mode, the interrupt and DMA request lines are deasserted. MMCI\_ICLK and MMCI\_FCLK can be switched off.

#### CAUTION

In force-idle mode, an idle request from the PRCM module during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the MMCI\_ICLK clock is alive.

The module exits force-idle mode when the PRCM module deasserts the idle request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

### Local Power Management

Table 24-8 describes the power-management features available for the MMC/SD/SDIOi modules.

**NOTE:** For information about source clock gating and a description of the sleep/wake-up transitions, see Section 3.1.1.1, *Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

**Table 24-8. Local Power-Management Features**

Feature	Registers	Description
Clock auto gating	MMCHS_SYSCONFIG AUTOIDLE bit	This bit allows a local power optimization inside the module by gating the MMCI_ICLK clock upon the interface activity, or gating the MMCI_FCLK clock upon the internal activity.
Slave idle modes	MMCHS_SYSCONFIG SIDLEMODE bit field	Force-idle, no-idle and smart-idle modes are available.
Clock activity	MMCHS_SYSCONFIG CLOCKACTIVITY bit field	For configuration details, see Table 24-9.
Master standby modes	MMCHS_SYSCONFIG STANDBYMODE bit field	Force-idle, no-idle, smart-idle modes are available.
Global wake-up enable	MMCHS_SYSCONFIG ENAWAKEUP bit	This bit enables the wake-up feature at the module level.

**Table 24-8. Local Power-Management Features (continued)**

Feature	Registers	Description
Wake-up sources enable	MMCHS_HCTL register	This register holds one active-high enable bit per event source that is able to generate a wake-up signal.

**Table 24-9. Clock Activity Settings**

CLOCKACTIVITY Values	Clock State When Module is in IDLE State		Features Available When Module is in IDLE State	Wake-Up Events
	MMCi_ICLK	MMCi_FCLK		
00	OFF	OFF	None	Card interrupt
10	OFF	ON	None	
01	ON	OFF	None	
11	ON	ON	All	

**CAUTION**

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY and MMCi clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**24.4.4 Interrupt Requests**

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the MMCi.MMCHS\_STAT register; it indicates which service is required.
- The interrupt status enable bits of the MMCi.MMCHS\_IE register enable or disable the automatic update of the MMCi.MMCHS\_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the MMCi.MMCHS\_ISE register enable or disable the transmission of an interrupt request on the interrupt line MMCi\_IRQ (from the MMC/SD/SDIOi host controller to the MPU subsystem INTC) on an event-by-event basis.

If an interrupt status is disabled in the MMCi.MMCHS\_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the MMCi.MMCHS\_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 0x1 (the MMC/SD/SDIOi host controller updates the status bit) in the MMCi.MMCHS\_STAT register. If later a mask is applied on the interrupt in the MMCi.MMCHS\_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the MMCi.MMCHS\_STAT register and the corresponding mask is removed from the MMCi.MMCHS\_ISE register, the interrupt status is not asserted again in the MMCi.MMCHS\_STAT register and the MMC/SD/SDIOi host controller does not transmit an interrupt request.

**CAUTION**

If the buffer write ready (BWR) interrupt or the buffer read ready (BRR) only interrupt are not serviced and are cleared in the MMCi.MMCHS\_STAT register, and the corresponding mask is removed, then the MMC/SD/SDIOi host controller waits for the service of the interrupt without updating the status MMCi.MMCHS\_STAT register or transmitting an interrupt request.

[Table 24-10](#) lists the event flags, and their mask, that can cause module interrupts.

Table 24-10. Events

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[29] BADA	MMCHS_IE[29] BADA_ENABLE	MMCi_IRQ	<p>Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed:</p> <p>This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE[11] BRE = 0)</p> <p>This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_STATE[10] BWE = 0)</p>
MMCHS_STAT[28] CERR	MMCHS_IE[28] CERR_ENABLE	MMCi_IRQ	Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5, or R5b. Only bits referenced as type E (error) in the status field in the response can set a card status error. An error bit in the response is flagged only if the corresponding bit in the card status response error MMCHS_CSRE is set. There is no card error detection for the autoCMD12 command.
MMCHS_STAT[25] ADMAE	MMCHS_IE[25] ADMAE_ENABLE	MMCi_IRQ	ADMA error. This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA error status register. In addition, the host controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state.
MMCHS_STAT[24] ACE	MMCHS_IE[24] ACE_ENABLE	MMCi_IRQ	Auto CMD12 error. This bit is set automatically when one of the bits in the auto CMD12 error status register changes from 0 to 1.
MMCHS_STAT[22] DEB	MMCHS_IE[22] DEB_ENABLE	MMCi_IRQ	Data end bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on the DAT line or at the end position of the CRC status in write mode.
MMCHS_STAT[21] DCRC	MMCHS_IE[21] DCRC_ENABLE	MMCi_IRQ	Data CRC error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position 010 token during a block write command.
MMCHS_STAT[20] DTO	MMCHS_IE[20] DTO_ENABLE	MMCi_IRQ	Data time-out error. This bit is set automatically according to the following conditions: <ul style="list-style-type: none"> <li>– Busy time-out for R1b, R5b response type</li> <li>– Busy time-out after write CRC status</li> <li>– Write CRC status time-out</li> <li>– Read data time-out</li> </ul>
MMCHS_STAT[19] CIE	MMCHS_IE[19] CIE_ENABLE	MMCi_IRQ	Command index error. This bit is set automatically when the response index differs from the corresponding command index previously emitted. The check is enabled through the MMCHS_CMD[20] CICE bit.
MMCHS_STAT[18] CEB	MMCHS_IE[18] CEB_ENABLE	MMCi_IRQ	Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.
MMCHS_STAT[17] CCRC	MMCHS_IE[17] CCRC_ENABLE	MMCi_IRQ	Command CRC error. This bit is set automatically when there is a CRC7 error in the command response. CRC check is enabled through the MMCHS_CMD[19] CCCE bit.
MMCHS_STAT[16] CTO	MMCHS_IE[16] CTO_ENABLE	MMCi_IRQ	Command time-out error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within five clock cycles, the time-out is still detected at 64 clock cycles.

**Table 24-10. Events (continued)**

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[15] ERRI	MMCHS_IE[15] ERRI_ENABLE	MMCi_IRQ	Error interrupt. If any of the bits in the error interrupt status register (MMCHS_STAT[24:15]) are set, this bit is set to 1.
MMCHS_STAT[10] BSR	MMCHS_IE[10] BSR_ENABLE	MMCi_IRQ	Boot status received interrupt. This bit is set automatically when the MMCHS_CON[18] BOOT_CF0 bit is set to 0x1 or 0x2 and a boot status is received on the dat0 line. This interrupt is useful only for the MMC card.
MMCHS_STAT[8] CIRQ	MMCHS_IE[8] CIRQ_ENABLE	MMCi_IRQ	Card interrupt. This bit is used only for SD, SDIO, and CE-ATA cards. In 1-bit mode, the interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, the interrupt source is sampled during the interrupt cycle. In CE-ATA mode, the interrupt source is detected when the card drives the CMD line to 0 during one cycle after data transmission end.
MMCHS_STAT[5] BRR	MMCHS_IE[5] BRR_ENABLE	MMCi_IRQ	Buffer read ready This bit is set automatically during a read operation to the card (see class 2 block-oriented read commands) when one block specified by the MMCHS_BLK[10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the LH needs to empty the buffer by reading it.
MMCHS_STAT[4] BWR	MMCHS_IE[4] BWR_ENABLE	MMCi_IRQ	Buffer write ready This bit is set automatically during a write operation to the card (see class 4 block-oriented write command) when the host can write a complete block as specified by the MMCHS_BLK[10:0] BLEN bit field. It indicates that the memory card has emptied one block from the buffer and that the LH can write one block of data into the buffer.
MMCHS_STAT[3] DMA	MMCHS_IE[3] DMA_ENABLE	MMCi_IRQ	DMA interrupt: This status is set when an interrupt is required in the ADMA instruction and after the data transfer completes.
MMCHS_STAT[2] BGE	MMCHS_IE[2] BGE_ENABLE	MMCi_IRQ	Block gap event. When a stop at block gap is requested (MMCHS_HCTL[16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.
MMCHS_STAT[1] TC	MMCHS_IE[1] TC_ENABLE	MMCi_IRQ	Transfer completed. This bit is always set when a read/write transfer is complete or between two blocks when the transfer is stopped because of a stop at block gap request (MMCHS_HCTL[16] SBGR). - In read mode: This bit is automatically set on completion of a read transfer (MMCHS_PSTATE[9] RTA). - In write mode: This bit is automatically set on completion of the DAT line use (MMCHS_PSTATE[2] DLA).

**Table 24-10. Events (continued)**

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[0] CC	MMCHS_IE[0] CC_ENABLE	MMCi_IRQ	Command complete This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[0] CMDI). If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command time-out error (MMCHS_STAT[16] CTO) has higher priority than command complete (MMCHS_STAT[0] CC). If a response is expected but none is received, then a command time-out error is detected and signaled, instead of the command complete interrupt.

**NOTE:** To send an interrupt request to the MMCi\_IRQ line, the mask/unmask bit must be set in the MMCi.MMCHS\_IE and MMCi.MMCHS\_ISE registers.

The MMC/SD/SDIOi host controller supports interrupt-driven operation and polling.

#### 24.4.4.1 Interrupt-Driven Operation

An interrupt enable bit must be set in the MMCi.MMCHS\_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

1. Read the MMCi.MMCHS\_STAT register to identify which event occurred.
2. Write 1 into the corresponding bit of the MMCi.MMCHS\_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this returns 0).

**NOTE:** In the MMCi.MMCHS\_STAT register, the card interrupt (CIRQ) and error interrupt (ERRI) bits cannot be cleared.

The MMCi.MMCHS\_STAT[8] CIRQ status bit must be masked by disabling the MMCi.MMCHS\_IE[8] CIRQ\_ENABLE bit (set to 0x0), and then the interrupt routine must clear the SDIO interrupt source in the SDIO card common control register (CCCR).

The MMCi.MMCHS\_STAT[15] ERRI bit is automatically cleared when all status bits in the MMCi.MMCHS\_STAT[31:16] bit field are cleared.

#### 24.4.4.2 Polling

When the interrupt capability of an event is disabled in the MMCi.MMCHS\_ISE register, the interrupt line is not asserted:

- Software can poll the status bit in the MMCi.MMCHS\_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCi.MMCHS\_STAT register clears the interrupt status and does not affect the interrupt line state.

**NOTE:** Refer to the previous note concerning CIRQ and ERRI bits clearing.

#### 24.4.5 DMA Modes

Two DMA managements can be used to load data from memory to the internal buffer of the controller (or vice versa). These modes are exclusive and depend on the module integration.

- DMA master mode

DMA master mode is selected by setting the [MMCHS\\_CON\[20\] DMA\\_MNS](#) bit to 1. In this case, the controller has direct access to data using a specific algorithm called ADMA2 (prevents the system from being interrupted). Data are exchanged using the L3 master interface, which supports burst accesses to maximize throughput.

---

**NOTE:** This mode is supported only by modules connected to the L3 interconnect. See [Section 24.1](#) for more information and/or check the value of the [MMCHS\\_HL\\_HWINFO\[0\] MADMA\\_EN](#) bit.

This mode is available for modules MMC1 and MMC2.

---

- **DMA slave mode**

DMA slave mode is selected by setting the [MMCHS\\_CON\[20\] DMA\\_MNS](#) bit to 0. In this case, the controller is slave on the DMA transaction managed by two separated requests (MMCi\_DMA\_TX and MMcI\_DMA\_RX).

---

**NOTE:** This mode is implied by modules that are not connected to the L3 interconnect (regardless of the value of the [MMCHS\\_CON\[20\] DMA\\_MNS](#) bit). See [Section 24.1](#) for more information and/or to check the value of the [MMCHS\\_HL\\_HWINFO\[0\] MADMA\\_EN](#) bit.

This mode is available for modules MMC3, MMC4, and MMC5.

---

#### 24.4.5.1 MASTER DMA Operations

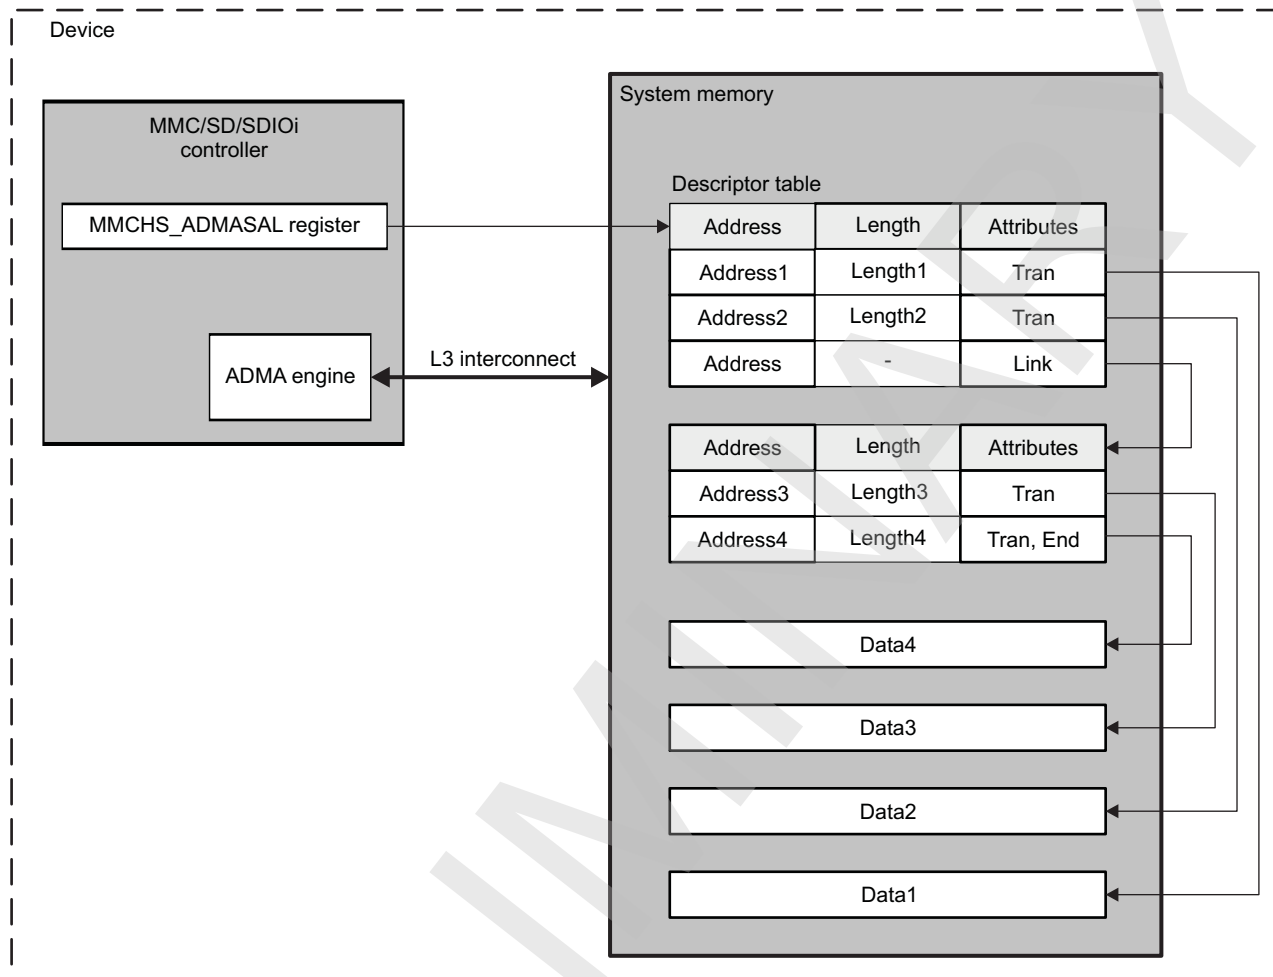

The MMC/SD/SDIOi host controller has direct access to the internal data. This feature is called advanced DMA (ADMA). It follows a specific algorithm (ADMA2) defined by an instruction in memory that starts at an address previously loaded in the [MMCHS\\_ADMASAL](#) register before any data command issued to the MMC card. Only 32-bit address spacing is supported by the controller for data storage.

---

**NOTE:** This mode is supported only by modules connected to the L3 interconnect. See [Section 24.1](#) for more information and/or to check the value of the [MMCHS\\_HL\\_HWINFO\[0\] MADMA\\_EN](#) bit.

---

These instructions must be loaded by software in a 32-bit-addressed descriptor table in system memory, as shown in [Figure 24-18](#). In this case the [MMCHS\\_ADMASAL](#) register is used as the program address pointer

**Figure 24-18. ADMA Block Diagram Overview**

mmchs-018

**24.4.5.1.1 Descriptor Table Description**

Each descriptor line contains an address, a length, and attributes fields. The attributes define which operation will be processed. Every descriptor line is a 64-bit width register that is fetched in the controller using the L3 master interface, and requires two 32-bit accesses to memory.

Table 24-11 shows the structure of a descriptor line.

**Table 24-11. Descriptor Line Overview**

Address Field		Length		Reserved		Attributes					
63	32	31	16	15	6	5	4	3	2	1	0
32-bit Address		16-bit Length		0x0		Act2	Act1	0	Int	Ent	Valid

The attribute of the descriptor line is divided into two parts:

- Attributes[5:4]: The action to be processed by the ADMA engine
- Attributes[3:0]: Additional parameters characterizing the behavior of the ADMA engine

Table 24-12 describes the available actions of a descriptor line.

**Table 24-12. Available Actions of a Descriptor Line**

Act2	Act1	Symbol	Comment	Operation
0	0	Nop	No operation	Do not execute the current line and go to the next line.
0	1	Rsv	Reserved	Reserved action. Behaves the same as the Nop command.
1	0	Tran	Transfer data	Transfer data of one descriptor line.
1	1	Link	Link descriptor	Link to another descriptor.

Table 24-13 describes the additional parameters of a descriptor line.

**Table 24-13. Additional Parameters of a Descriptor Line**

Bit	Description
Valid	Valid = 1 indicates that this descriptor line is effective. If Valid = 0, an ADMA error interrupt is generated and the ADMA is stopped. This prevents runaways.
End	End = 1 indicates the end of a descriptor. The transfer-complete interrupt is generated when the operation of the descriptor line is complete.
Int	Int = 1 generates a DMA interrupt when the operation of the descriptor line is complete.

#### 24.4.5.1.2 Requirements for Descriptors

The following sections discuss restrictions and tips on how to correctly configure the descriptors to be used by the ADMA engine.

##### 24.4.5.1.2.1 Data Length

There are three requirements to program descriptors:

- The minimum unit of address is 4 bytes.
- The maximum data length of each descriptor line is less than 64KB.
- Total length = Length<sub>1</sub> + Length<sub>2</sub> + Length<sub>3</sub> + ... + Length<sub>n</sub> must be a multiple of the block size.

If the total length of a descriptor is not a multiple of the block size, data transfer with the ADMA engine may not have been terminated. In this case, the controller returns a data time-out event and the transfer is aborted.

The block count register (the [MMCHS\\_BLK\[31:16\]](#) NBLK bit field) is defined as 16 bits and limits data transfers to a maximum of 65,535 blocks. If the ADMA data transfer size is less than or equal to the 65,535-block transfer, the block count register can be used. In this case, the total length of the descriptor table must be equivalent to "block size" by "block count." If the ADMA data transfer is greater than 65,535 blocks, the block count register must be disabled by setting the block count enable bit (the [MMCHS\\_CMD\[1\]](#) BCE bit) to 0. In this case, the length of the data transfer is not designated by the block count but by the descriptor table.

---

**NOTE:** The timing for detecting the last block on the SD bus may differ, which affects control of the read transfer active ([MMCHS\\_PSTATE\[9\]](#) RTA), write transfer active ([MMCHS\\_PSTATE\[8\]](#) WTA), and DAT line active ([MMCHS\\_PSTATE\[2\]](#) DLA) bits. In case of a read operation, more blocks than required may be read from the card. The host driver must ignore an out-of-range error if the read operation is for the last block of the memory area.

---

##### 24.4.5.1.2.2 Supported Features

The ADMA engine does not support the suspend/resume function. However, the stop and continue functions are available.

When the stop-at-block-gap-request ([MMCHS\\_HCTL\[16\]](#) SBGR bit) is set during the ADMA operation, the block gap event interrupt is generated when the ADMA is stopped at block gap ([MMCHS\\_STAT\[2\]](#) BGE bit). The host controller must stop the ADMA read operation by using read wait or by stopping the SD clock. While stopping ADMA, SD commands cannot be issued.

### 24.4.5.1.2.3 Error Generation

When an error occurs during an ADMA transfer, the ADMA operation is stopped and the ADMA error interrupt is generated. The ADMA error state field (the `MMCHS_ADMAES[1:0]` AES bit field) holds the state of the ADMA when it is stopped. Software can identify the erroneous descriptor line by using the following method:

- if ADMA stopped at `ST_FDS` state, the ADMA system address register (`MMCHS_ADMASAL`) points to the erroneous descriptor line
- If ADMA stopped at `ST_TFR` or `ST_STOP` state, the ADMA system address register points to the descriptor line following the erroneous one.

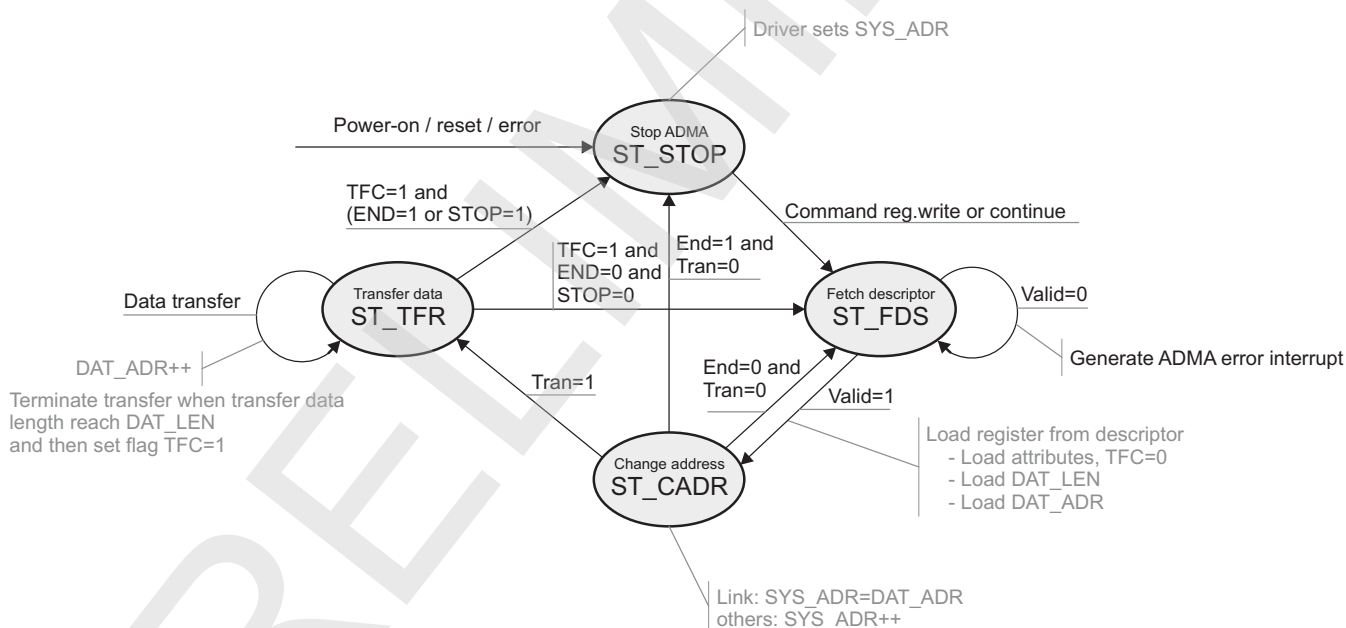

### 24.4.5.1.3 Advanced DMA Description

The ADMA is a DMA controller embedded in each eMMC controller. It can be seen as a small sequencer that fetches a descriptor line and executes the corresponding action. The base address of the descriptor table is stored in the `MMCHS_ADMASAL` register.

**NOTE:** Software must write the base address of the descriptor table in the `MMCHS_ADMASAL` register before the first use of the ADMA engine.

The ADMA program is executed according to descriptor attributes (see [Section 24.4.5.1.1, Descriptor Table Description](#)) and a finite state-machine (FSM), as shown in [Figure 24-19](#).

**Figure 24-19. ADMA Finite State-Machine**

mmchs-019

[Table 24-14](#) describes each state of the ADMA FSM.

**Table 24-14. ADMA2 States Description**

State Name	Operation
<code>ST_FDS</code> (fetch descriptor)	ADMA2 fetches a descriptor line and sets parameters in internal registers. It then goes to the <code>ST_CADR</code> state.
<code>ST_CADR</code> (change address)	Link operation loads another descriptor address to the ADMA system address register ( <code>MMCHS_ADMASAL</code> ). In other operations, the ADMA system address register is incremented to point to the next descriptor line. If <code>End = 0</code> , go to <code>ST_FDS</code> state. <b>NOTE:</b> ADMA2 is not stopped at this state if some errors occur.

**Table 24-14. ADMA2 States Description (continued)**

State Name	Operation
ST_TFR (transfer data)	Data transfer of one descriptor line is executed between system memory and the SD card: <ul style="list-style-type: none"> <li>• if data transfer continues (End = 0) go to ST_FDS state.</li> <li>• if data transfer completes, go to ST_STOP state.</li> </ul>
ST_STOP (stop DMA)	ADMA2 stays in this state in the following cases: <ul style="list-style-type: none"> <li>• After power on reset (POR) or software reset</li> <li>• All descriptor data transfers are complete.</li> </ul> If a new ADMA operation is stated by writing the command register, go to ST_FDS state.

Table 24-15 gives the description of each symbol used in the ADMA FSM flow chart (see Figure 24-19).

**Table 24-15. ADMA FSM Symbol Definition**

Symbol	Definition
SYS_ADR	ADMA system address register
SYS_ADR++	Point to next descriptor line
DAT_ADR	Data address register (internal)
DAT_LEN	Data length register (internal)
TFC	Transfer complete flag (internal)
STOP	Stop-at-block-gap request

#### 24.4.5.2 SLAVE DMA Operations

The MMC/SD/SDIOi host controller can be interfaced with a DMA controller. At the system level, the advantage is to discharge the LH of the data transfers. The module does not support wide DMA access (above 1024 bytes) for SD cards, as specified in the *SD Card Specification* and *SD Host Controller Standard Specification*.

**NOTE:** This mode is implied by modules that are not connected to the L3 interconnect (regardless of the value of the `MMCHS_CON[20]` `DMA_MNS` bit). See Section 24.4.5.1, *MASTER DMA Operations*, for more information and/or to check the value of the `MMCHS_HL_HWINFO[0]` `MADMA_EN` bit.

The DMA request is issued if the three following conditions are met:

- The `MMCi.MMCHS_CMD[0]` `DE` bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the `sdmmc_i_cmd` line.
- There is enough space in the buffer of the MMC/SD/SDIOi host controller to write an entire block (BLEN writes).

##### 24.4.5.2.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal `MMCi_DMA_RX` is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the `MMCi.MMCHS_BLK[10:0]` `BLEN` bit field.

The `MMCi_DMA_RX` signal is deasserted to its inactive level when the sDMA has read one word from the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the `BLEN` field block size.

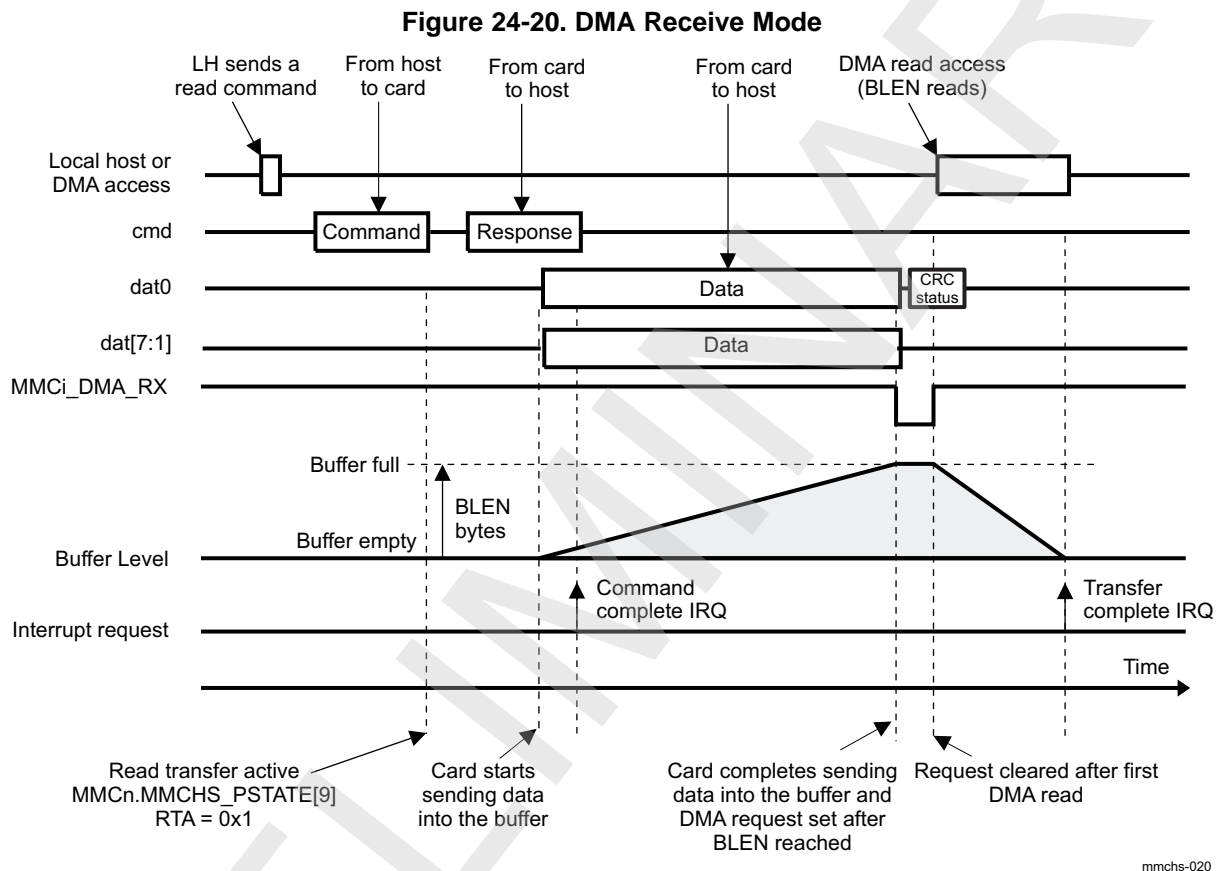

New DMA requests are internally masked if the sDMA has not read exactly `BLEN` bytes and a new complete block is not ready. Because DMA accesses are 32-bit accesses, the number of sDMA read is  $\text{Integer}(\text{BLEN}/4) + 1$ .

The receive buffer never overflows. In multiple block transfers for block sizes above 512 bytes, when the buffer becomes full, the `sdmmc_clk` clock signal (provided to the card) is momentarily stopped until the sDMA or the MPU performs a read access, which reads a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 24-20 shows DMA receive mode.

#### 24.4.5.2.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal `MMCi_DMA_TX` is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the `MMChs.MMCHS_BLK[10:0]` BLEN bit field.

The `MMCi_DMA_TX` signal is deasserted to its inactive level when the sDMA has written one word to the buffer.

Only one request is sent per block; the DMA controller can make a one-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN field block size.

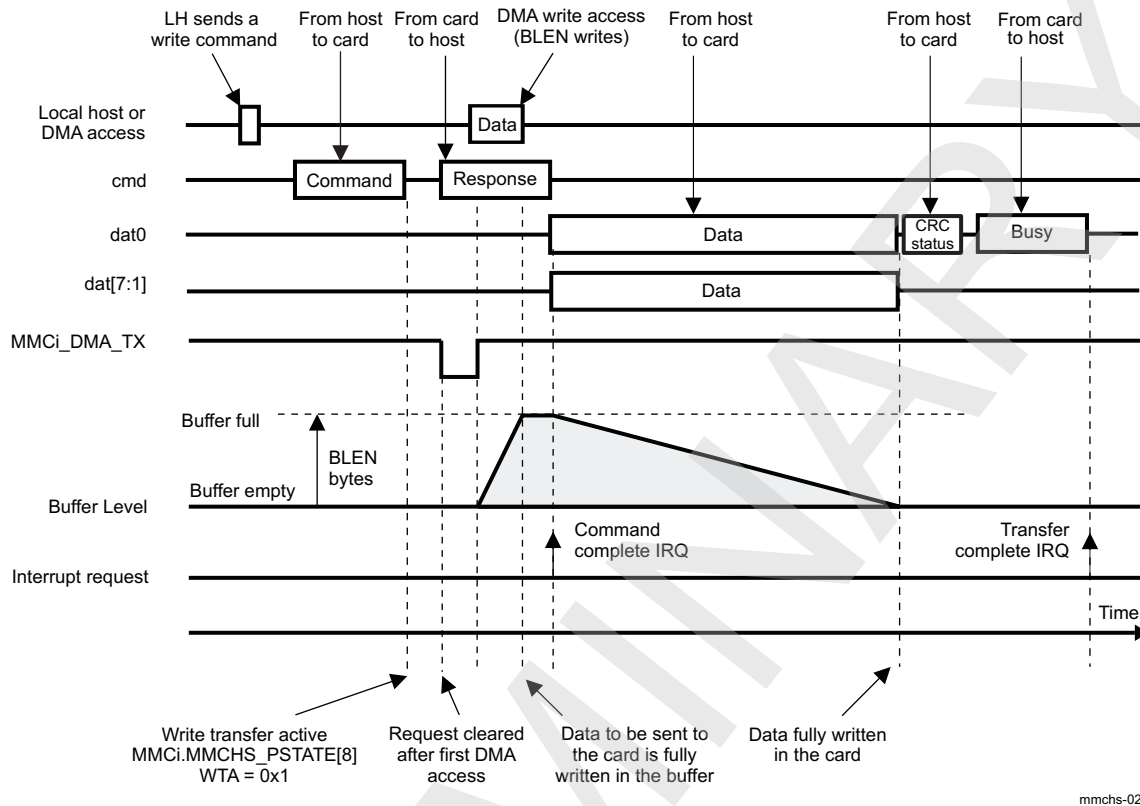

New DMA requests are internally masked if the sDMA has not written exactly BLEN bytes (because DMA accesses are 32-bit accesses, the number of sDMA read is  $\text{Integer}(\text{BLEN}/4) + 1$ ) and if there is not enough memory space to write a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 24-21 shows DMA transmit mode.

Figure 24-21. DMA Transmit Mode

### 24.4.6 Mode Selection

The MMC/SD/SDIO host controller can be used in two modes: MMC and SD/SDIO. It has been designed to be the most transparent with the type of card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each given card type, there are corresponding commands. Some commands are not supported by all cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification, Part E1*.

The purpose of the module is to transfer commands and data to whatever card is connected, respecting the protocol of the connected card.

Writes and reads to the card must respect the appropriate protocol of that card.

### 24.4.7 Buffer Management

#### 24.4.7.1 Data Buffer

The MMC/SD/SDIOi host controller uses a data buffer. This buffer transfers data from one data bus (Interconnect) to another data bus (SD SDIO or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (Interconnect and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than that of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the data buffer, prefetch buffer, and post-write buffer is the 32-bit register `MMCi.MMCHS_DATA` register. A write access to the `MMCi.MMCHS_DATA` register followed by a read access from the `MMCi.MMCHS_DATA` register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the `MMCi.MMCHS_DATA` register and the data of the read access to the `MMCi.MMCHS_DATA` register are different.

The number of 32-bit accesses to the `MMCi.MMCHS_DATA` register that are needed to read (or write) a data block with a size of the `MMCi.MMCHS_BLK[10:0]` `BLEN` bit field equals the rounded up result of `BLEN` divided by 4.

The maximum block size supported by the host controller is hard-coded in the register `MMCi.MMCHS_CAPA[17:16]` `MBL` bit field and cannot be changed.

A read access to the `MMCi.MMCHS_DATA` register is allowed only when the buffer read enable status is set to 1 (the `MMCi.MMCHS_PSTATE[11]` `BRE` bit); otherwise, a bad access (the `MMCi.MMCHS_STAT[29]` `BADA` bit) is signaled.

A write access to the `MMCi.MMCHS_DATA` register is allowed only when the buffer write enable status is set to 1 (the `MMCi.MMCHS_PSTATE[10]` `BWE` bit); otherwise, a bad access (the `MMCi.MMCHS_STAT[29]` `BADA` bit) is signaled and the data is not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to `MEM_SIZE/2` (in double-buffering), two data transfers can occur at the same time from one data bus to the other data bus and vice versa. The MMC/SD/SDIO host controller uses the two portions of the data buffer in a ping-pong manner so that storing and reading the first and second portions of the data buffer are automatically interchanged from time to time so that data may be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) is being stored into the other portion, and vice versa. When `BLEN` is less than or equal to `0x200` (that is, less than or equal to 512 bytes), each of the two portions of the buffer that can be used have a size of `BLEN` (that is, 32 bits  $\times$  `BLEN` divided by 4). No more than this total size of  $2 \times 32 \text{ bits} \times \text{BLEN} \text{ divided by } 4$  can be used.

#### CAUTION

The `MMCi.MMCHS_CMD[4]` `DDIR` bit must be configured before a transfer to indicate the direction of the transfer.

Figure 24-22 and Figure 24-23 show the buffer management for a write and for a read, respectively.

Figure 24-22. Buffer Management for a Write

mmchs-022

**Figure 24-23. Buffer Management for a Read**

mmchs-023

- When the size of the data block to transfer is larger than  $\text{MEM\_SIZE}/2$ , only one data transfer can occur at a time from one data bus to the other data bus. The MMC/SD/SDIOi host controller uses the entire data buffer as a single portion. In this mode, a bad access (the MMCi.MMCHS\_STAT[29] BADA bit) is signaled when two data transfers occur at the same time from one data bus to the other data bus, and vice versa.

#### 24.4.7.1.1 Memory Size, Block Length, and Buffer-Management Relationship

The maximum block length and buffer management that can be targeted by the system depend on the memory depth setting (see [Table 24-16](#)).

**NOTE:** Double-buffering is always the buffer management for larger memory depth ( $\text{MEM\_SIZE} = 4096$ ).

**Table 24-16. Memory Size, BLEN, and Buffer Relationship**

Memory Size (MMCHS_HL_HWINFO[5:2] MEM_SIZE in bytes)	512	1024	2048	4096
Maximum block length supported	512	1024	2048	2048
Double-buffering for maximum block length	N/A	BLEN<=512	BLEN<=1024	BLEN<=2048
Single-buffering for block length	BLEN<=512	512<BLEN<=1024	1024<BLEN<=2048	N/A

**NOTE:** For single-buffering management, throughput on the MMC bus interface deteriorates in multiblock transfers, because the controller must wait for the filling or emptying of the buffer between each block transfer on the MMC bus. The clock is maintained on write MMC transfers (the MMCHS\_CMD[3] DDIR bit is 0) and halted on read MMC transfers (the MMCHS\_CMD[3] DDIR bit is 1).

#### 24.4.7.1.2 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers:
  - MMCh.MMCHS\_STAT[29] BADA: Bad access to data space
  - MMCh.MMCHS\_STAT[5] BRR: Buffer read ready
  - MMCh.MMCHS\_STAT[4] BWR: Buffer write ready
- Status registers:
  - MMCh.MMCHS\_PSTATE[11] BRE: Buffer read enable
  - MMCh.MMCHS\_PSTATE[10] BWE: Buffer write enable

#### 24.4.8 Transfer Process

The process of a transfer is dependent on the type of command. It can be with or without a response, and with or without data.

##### 24.4.8.1 Different Types of Commands

Different types of commands are specific to the MMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, *SDIO Card Specification, Part E1*, or *SD Card Specification, Part A2*, *SD Host Controller Standard Specification*.

##### 24.4.8.2 Different Types of Responses

Different types of responses are specific to the MMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2*, *SD Host Controller Standard Specification*.

Table 24-17 describes how the MMC, SD, and SDIO responses are stored in the MMCHS\_RSPxx registers.

**Table 24-17. MMC, SD, SDIO Responses in the MMCHS\_RSPxx Registers**

Kind of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6, R7	RESP[39:8] <sup>(1)</sup>	MMCHS_RSP10[31:0]
R1b (Auto CMD12 response)	RESP[39:8] <sup>(1)</sup>	MMCHS_RSP76[31:0]
R2	RESP[127:0] <sup>(1)</sup>	MMCHS_RSP76[31:0] MMCHS_RSP54[31:0] MMCHS_RSP32[31:0] MMCHS_RSP10[31:0]

<sup>(1)</sup> RESP refers to the command response format described in the specifications mentioned.

When the host controller modifies part of the MMCHS\_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the MMCHS\_RSP76[31:0] register because the host controller may have a multiple block data DAT line transfer executing concurrently with a command. This allows the host controller to avoid overwriting the Auto CMD12 response with the command response stored in the MMCHS\_RSP10 register, and vice versa.

#### 24.4.9 Transfer or Command Status and Errors Reporting

Flags in the MMC/SD/SDIOi host controller show the status of communication with the card:

- A time-out (of a command, data, or response)
- A CRC error

Error conditions generate interrupts. For more information, see [Table 24-18](#) and the register description.

**Table 24-18. CC and TC Values Upon Error Detected**

Error Hold in MMCi.MMCHS_STAT	CC	TC	Comments
29 BADA			No dependency with CC or TC BADA is related to the MMCHS_DATA register accesses. Its assertion is not dependent on the ongoing transfer.
28 CERR	1		CC is set upon CERR.
22 DEB		1	TC is set upon DEB.
21 DCRC		1	TC is set upon DCRC.
20 DTO			DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO.
19 CIE	1		CC is set upon CIE.
18 CEB	1		CC is set upon CEB.
17 CCRC	1		CC can be set upon CCRC. See CTO comment.
16 CTO			CTO and CC are mutually exclusive. CIE, CEB and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: It indicates a command abort due to contention on the CMD line. In this case no CC appears.

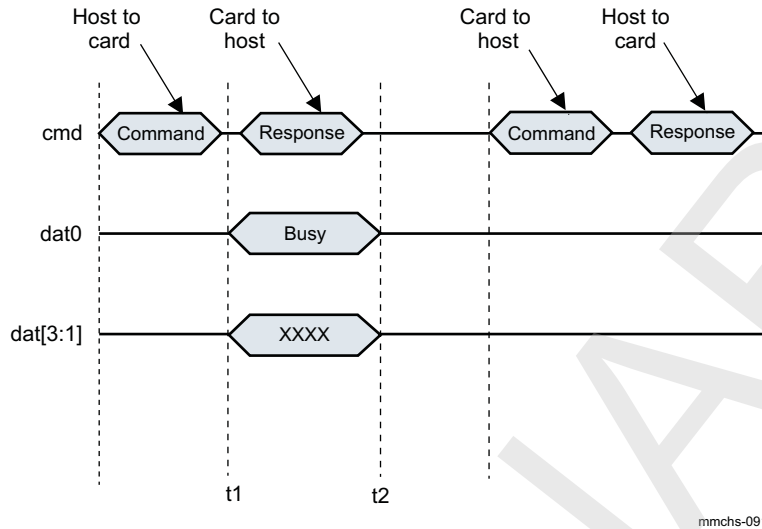

A MMCHS\_STAT[21] DCRC event can be asserted in the following conditions:

- Busy time-out for R1b, R5b response type
- Busy time-out after write CRC status
- Write CRC status time-out
- Read data time-out
- Boot acknowledge time-out

##### 24.4.9.1 Busy Time-Out for R1b, R5b Response Type

[Figure 24-24](#) shows the DCRC event condition asserted when there is busy time-out for Rb1, R5b response.

**Figure 24-24. Busy Time-Out for R1b, R5b Response Type**

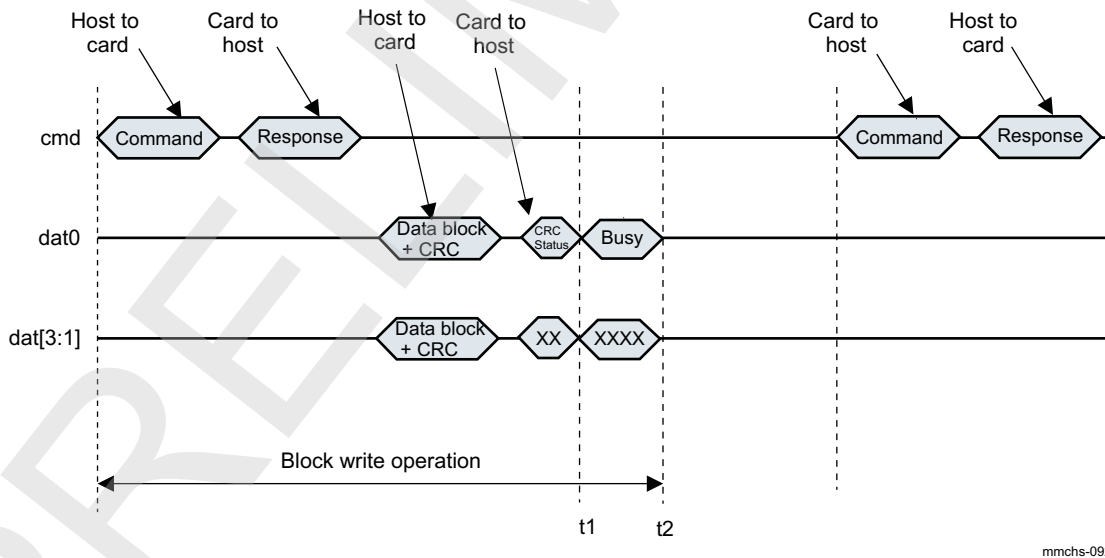

t1 – Data time-out counter is loaded and starts after R1b, R5b response type.  
t2 – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.

**24.4.9.2 Busy Time-Out After Write CRC Status**

Figure 24-25 shows the DCRC event condition asserted when there is busy time-out after write CRC status.

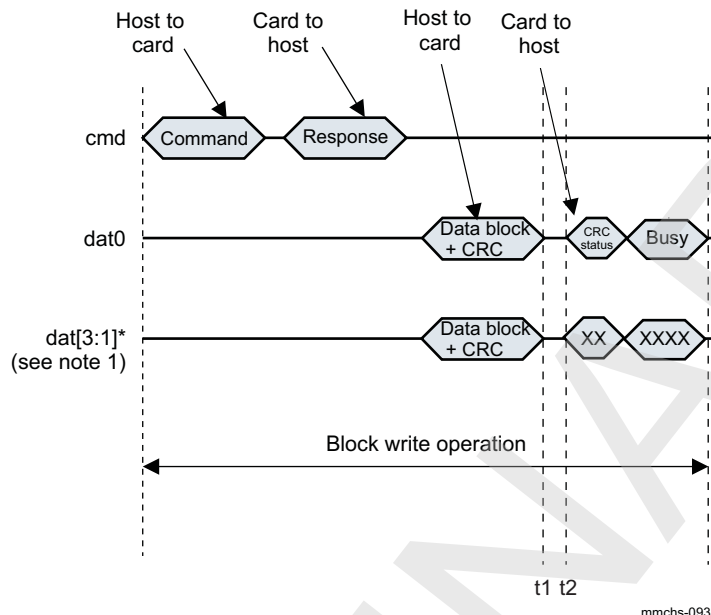

**Figure 24-25. Busy Time-Out After Write CRC Status**

t1 – Data time-out counter is loaded and starts after CRC status.  
t2 – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.

**24.4.9.3 Write CRC Status Time-Out**

Figure 24-26 shows the DCRC event condition asserted when there is write CRC status time-out.

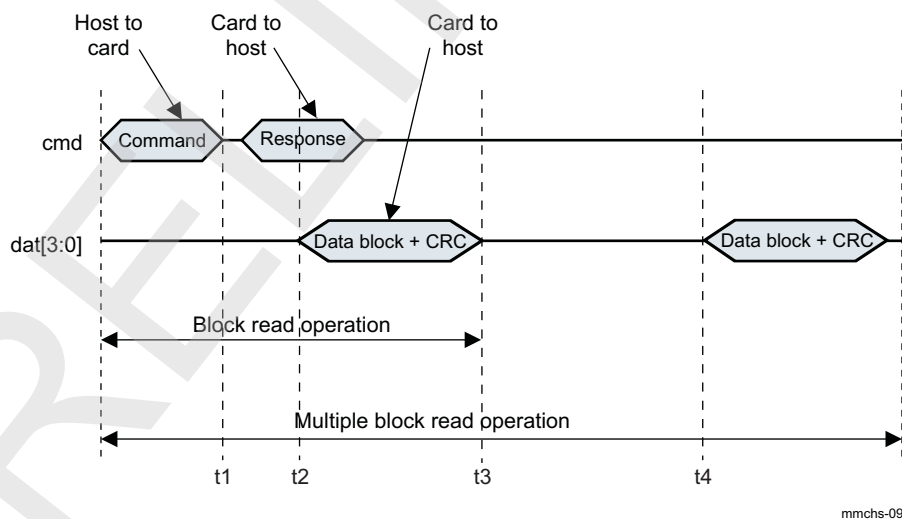

**Figure 24-26. Write CRC Status Time-Out**

t1 – Data time-out counter is loaded and starts after data block + CRC.

t2 – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.

#### 24.4.9.4 Read Data Time-Out

Figure 24-27 shows the DCRC event condition asserted when there is read data time-out.

**Figure 24-27. Read Data Time-Out**

t1 – Data time-out counter is loaded and starts after command transmission.

t2 – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.

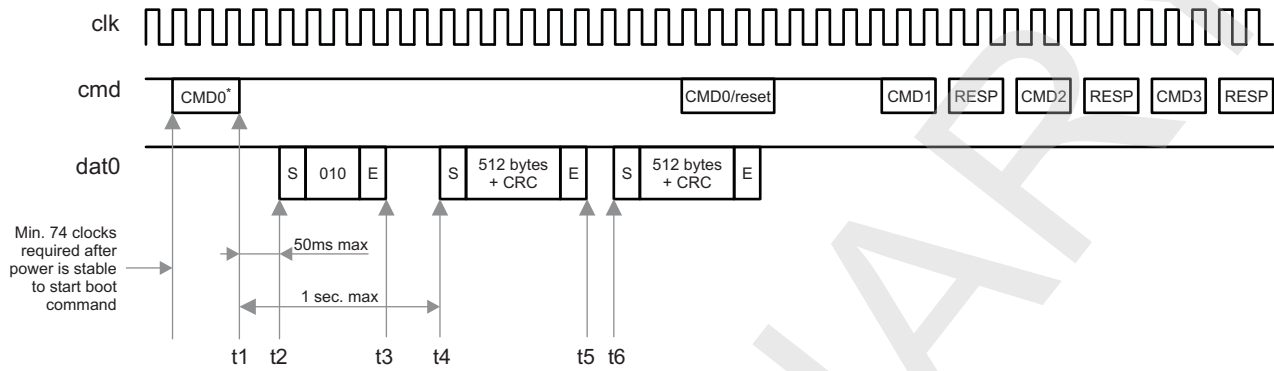

t3 – Data time-out counter is loaded and starts after data block + CRC transmission.

t4 – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.

24.4.9.5 Boot Acknowledge Time-Out

Figure 24-28 shows the DCRC event condition asserted when there is a boot acknowledge time-out and CMD0 is used.

Figure 24-28. Boot Acknowledge Time-Out When Using CMD0

\* Refer to MMC specification for correct Argument

mmchs-095

- t1 – Data time-out counter is loaded and starts after CMD0.
- t2 – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.
- t3 – Data time-out counter is loaded and starts.
- t4 – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.
- t5 – Data time-out counter is loaded and starts after data + CRC transmission.
- t6 – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.

Figure 24-28 shows the DCRC event condition asserted when there is boot acknowledge time-out and CMD0 is used.

Figure 24-29. Boot Acknowledge Time-Out When CMD Line Tied to 0

mmchs-096

- t1 – Data time-out counter is loaded and starts after the command line is tied to 0.
- t2 – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.
- t3 – Data time-out counter is loaded and starts.
- t4 – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.
- t5 – Data time-out counter is loaded and starts after data + CRC transmission.
- t6 – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.

### 24.4.10 Auto Command 12 Timings

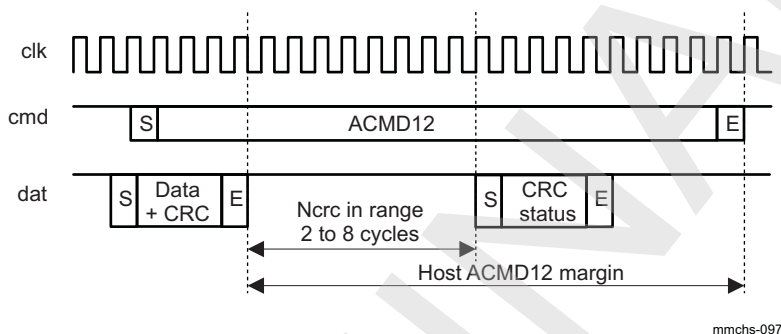

With the UHS definition of SD cards with higher frequency for MMC clock up to 208, the SD standard imposes a specific timing for the arrival of the auto command 12 (ACMD12) end bit.

#### 24.4.10.1 ACMD12 Timings During Write Transfer

A margin named *Nrc* in the range of two to eight cycles has been defined for SDR50 and SDR104 card components for write data transfers, because the ACMD12 end bit must arrive after the CRC status end bit.

Figure 24-30 shows the ACMD12 timings during write transfer.

**Figure 24-30. ACMD12 Timings During Write Transfer**

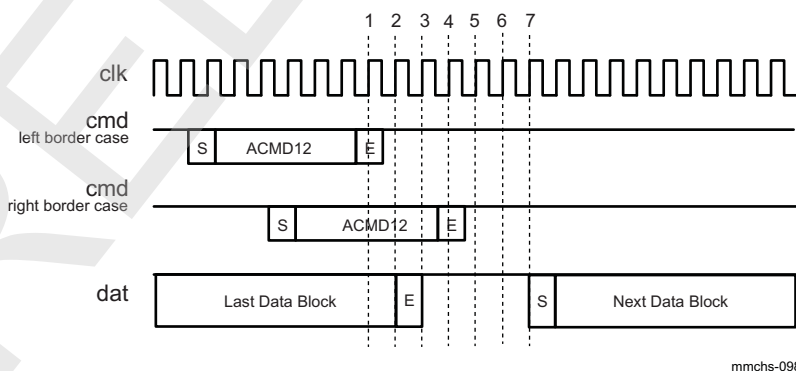

The host controller has a margin of 18 clock cycles to ensure that the ACMD12 end bit arrives after the CRC status. This margin does not depend on the MMC bus configuration, DDR, or standard transfer, 1-, 4-, or 8-bit bus width.

#### 24.4.10.2 ACMD12 Timings During Read Transfer

With UHS cards, the gap timing between two successive cards has been extended from two cycles to four cycles. It provides more flexibility for the host ACMD12 arrival to receive the last complete and reliable block. The MMCHS controller follows only the Left Border Case defined by the SD UHS specification.

Figure 24-31 shows ACMD12 timings during read transfer.

**Figure 24-31. ACMD12 Timings During Read Transfer**

The ACMD12 arrival sent by the host controller is not sensitive to the MMC bus configuration, whether it is a DDR or standard transfer and whether it is a 1-, 4-, or 8-bit bus width transfer.

### 24.4.11 Transfer Stop

Whenever a transfer is initiated, the transmission may be willed to stop while it is still not finished. Several cases are possible, depending on the transfer type:

- Multiple-block-oriented transfers (transfer length is known)

- Continuous stream transfers (transfer has an infinite length)

**NOTE:** Because the MMC/SD/SDIOi controller manages transfers based on a block granularity, the buffer accepts a block only if there is enough space to store it completely. Consequently, if a block is pending in the buffer, no command is sent to the card because the card clock will be shut off by the controller.

The MMC/SD/SDIOi controller includes two features that make a transfer stop more convenient and easier to manage:

- **ACMD12 (for MMC and SD only):**  
This feature is enabled by setting the MMCI.MMCHS\_CMD[2] ACEN bit to 0x1 (this setting is relevant for a MMC/SD transfer with a known number of blocks to transfer). When the ACMD12 feature is enabled, the MMC/SD/SDIOi controller automatically issues a CMD12 command when the expected number of blocks is exchanged.
- **Stop at block gap:**  
This feature is enabled by setting the MMCI.MMCHS\_HCTL[16] SBGR bit to 0x1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.
- **ADMA mode:**  
For ADMA-capable modules (MMC1 and MMC2) (see Section 24.4.5, DMA Modes, for more information), the last instruction can stop the transfer (the END bit is enabled in the descriptor line).

**NOTE:** For MMC and SD cards, the stop-at-block-gap feature is not supported in read mode.

For SDIO cards, this setting can be supported in read mode if the card has a read-wait capability.

Table 24-19 shows the common way to stop a transfer, indicating the command to send and the features to enable.

**Table 24-19. MMC/SD/SDIOi Controller Transfer Stop Command Summary**

		Write Transfer		Read Transfer	
		SD/MMC	SDIO	SD/MMC	SDIO
Single block		Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.
Multiblocks (finite or infinite)	Before the programmed block boundary	Send CMD12. Wait TC.	Send CMD52. Wait TC.	Send CMD12. Wait TC.	Send CMD52. Wait TC.
	Stop at the end of the transfer (finite transfer only)	ACMD12 active Transfer ends automatically. Wait TC.	Set MMCI.MMCHS_HCTL[16] SBGR bit to 0x1. Send CMD52. Wait TC.	ACMD12 active Transfer ends automatically. Wait TC.	<b>If READ_WAIT supported</b> Stop at block gap. Wait TC.  <b>If READ_WAIT not supported</b> Send CMD52. Wait TC.

**NOTE:** The MMC/SD/SDIOi controller sends the stop command to the card on a block boundary, regardless of when the command was written to the controller registers.

### 24.4.12 Retention Mode

This mode is enabled if generic parameter MMCHS\_HL\_HWINFO[6] RETMODE is set to 1 during module integration. The controller can enter into retention mode when the module was previously set in idle mode. When the module goes into retention mode all clocks are left inactive at low level except for registers that

are driven by a falling-edge clock, which are kept as free during retention mode. This also means that all divided functional clock subdomains are forced to low when the module enters into smart-idle mode. In force-idle mode, the system must ensure that all divided functional clocks are set inactive or in bypass mode by configuring the `MMCHS_SYSCTL` register correctly before entering into idle mode (under software responsibility).

### 24.4.13 Output Signals Generation

The MMC/SD/SDIO output signals can be driven on the falling edge or rising edge, depending on the `MMCHS_HCTL[2]` HSPE bit. This feature allows reaching better timing performance, and thus increasing data transfer frequency.

#### 24.4.13.1 Generation on Falling Edge of MMC Clock

The controller is by default in this mode to maximize hold timings. In this case, the `MMCHS_HCTL[2]` HSPE bit is set to 0.

Figure 24-32 shows the output signals of the module when generating from the falling edge of the MMC clock.

#### 24.4.13.2 Generation on Rising Edge of MMC Clock

This mode increases setup timings and allows reaching higher bus frequency. This feature is activated by setting the `MMCHS_HCTL[2]` HSPE bit to 1. The controller must be set in this mode to support SDR transfers.

---

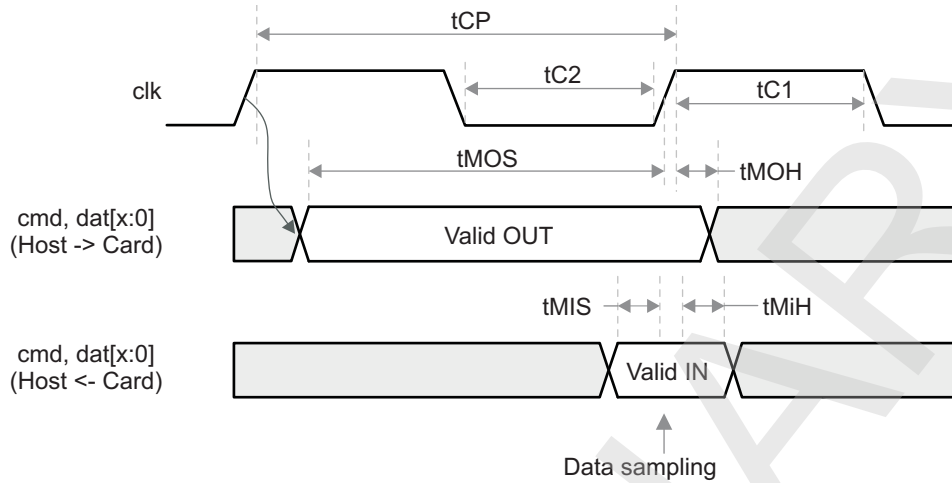

**NOTE:** Do not use this feature in DDR mode (when the `MMCHS_CON[19]` DDR bit is set to 1).

---

Figure 24-33 shows the output signals of the module when generating from the rising edge of the MMC clock.

Figure 24-33. Output Driven on Rising Edge

mmchs-025

#### 24.4.14 Card Boot Mode Management

Boot operation mode allows the MMC/SD/SDIOi host controller to read boot data from the connected slave (MMC device) by keeping CMD line low after power on (or sending CMD0 with specific argument) before issuing CMD1. The data can be read from the boot area or user area, depending on the register setting.

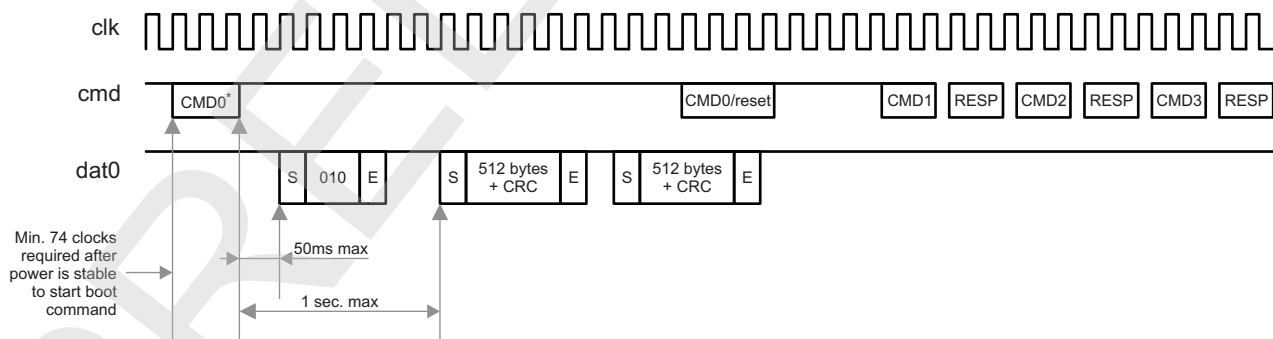

Power-on boot defines a way for the boot code to be accessed by the MMC/SD/SDIOi host controller without an upper-level software driver, speeding the time it takes for a controller to access the boot code.

The two possible ways to issue a boot command (issuing a CMD0 or driving the CMD line to 0 during the whole boot phase) are described in the following sections.

##### 24.4.14.1 Boot Mode Using CMD0

Figure 24-34 shows the timing diagram of a boot sequence using CMD0.

Figure 24-34. Boot Mode Using the CMD0 Timing Diagram

\* Refer to MMC specification for correct Argument

mmchs-026

For more information about how to configure the MMC/SD/SDIO host controller, see [Section 24.5.1.2.3.1, Boot Using the CMD0](#).

##### 24.4.14.2 Boot Mode With CMD Line Tied to 0

Figure 24-35 shows the timing diagram of a boot sequence with CMD line tied to 0.

**Figure 24-35. Boot Mode With CMD Line Tied to 0 Timing Diagram**

mmchs-027

For more information about how to configure the MMC/SD/SDIO host controller, see [Section 24.5.1.2.3.2, Boot With CMD Line Tied to 0](#).

#### 24.4.15 MMC CE-ATA Command Completion Disable Management

The MMC/SD/SDIOi host controller supports CE-ATA features, in particular the detection of command completion token. When a command that requires a command completion signal (the [MMCHS\\_CON\[12\]](#) CEATA and [MMCHS\\_CMD\[2\]](#) ACEN bits set to 1) is launched, the host system is no longer allowed to emit a new command in parallel to the data transfer unless it is a command completion disable token.

The settings to emit a command completion disable token are:

- The [MMCHS\\_CON\[12\]](#) CEATA is set to 1.
- The [MMCHS\\_CON\[2\]](#) HR set to 1.
- Clear the [MMCHS\\_ARG](#) register.
- Write into the [MMCHS\\_CMD](#) register with value 0x00000000.

When a command completion disable token was emitted (that is, the [MMCHS\\_STAT\[0\]](#) CC bit received), the host system is again allowed to emit another type of command (for example, a CMD12 to abort transfer).

A critical case can be encountered when command completion signal disable (CCSD) is emitted during the last data block transfer, and the sequence on the command line is sent close to the command completion signal (CCS) token sent by the card.

Three possible cases are:

- CCS is received immediately before CCSD is emitted:  
An interrupt CIRQ is generated with CCS detection, CCSD is transmitted to the card, and then an interrupt CC is generated when CCSD ends. In this case, the card considers the CCSD sequence.
- CCS is not generated or is generated during the CCSD transfer:  
The CCS bit cannot be detected (conflict is not possible because they drive the same level on the command line, and no CIRQ interrupt is generated; a CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:  
Only the interrupt CIRQ is generated when CCS is detected.

#### 24.4.16 Test Registers

Test registers are available to comply with the *SD Host Controller Specification*. This feature is useful to generate interrupts manually for driver debugging.

The force event register ([MMCHS\\_FE](#)) is used to control the error interrupt status and ACMD12 error status.

The system test register ([MMCHS\\_SYSTEST](#)) is used to control the signals that connect to I/O pins when the module is configured in the system test mode (the [MMCHS\\_CON\[4\]](#) MODE bit = 1) for boundary connectivity verification.

### 24.4.17 MMC/SD/SDIO Hardware Status Features

This section discusses the MMC/SD/SDIO hardware status features.

**Table 24-20. MMC/SD/SDIO Hardware Status Features**

Feature	Type	Register/Bit Field/Observability Control	Description
Interrupt flags		See <a href="#">Section 24.4.4</a> , <i>Interrupt Requests</i> .	
CMD line signal level	Status	<a href="#">MMCHS_PSTATE</a> [24] CLEV	Indicates the level of the cmd line
DAT lines signal level	Status	<a href="#">MMCHS_PSTATE</a> [23:20] DLEV	Indicates the level of the data lines
Buffer read enable	Status	<a href="#">MMCHS_PSTATE</a> [11] BRE	Readable data exists in the buffer.
Buffer write enable	Status	<a href="#">MMCHS_PSTATE</a> [10] BWE	Indicates whether there is enough space in the buffer to write BLEN bytes of data
Read transfer active	Status	<a href="#">MMCHS_PSTATE</a> [9] RTA	This status is used for detecting completion of a read transfer.
Write transfer active	Status	<a href="#">MMCHS_PSTATE</a> [8] WTA	This status indicates a write transfer active.
Data line active	Status	<a href="#">MMCHS_PSTATE</a> [2] DLA	Indicates whether the data lines are active
Command Inhibit (data lines)	Status	<a href="#">MMCHS_PSTATE</a> [1] DATI	Indicates whether issuing of command using data lines is allowed
Command inhibit (CMD line)	Status	<a href="#">MMCHS_PSTATE</a> [0] CMDI	Indicates whether issuing of command using CMD line is allowed

## 24.5 MMC/SD/SDIO Programming Guide

### 24.5.1 Low-Level Programming Models

#### 24.5.1.1 Global Initialization

##### 24.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the module has to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMC/SD/SDIO modules. For more information, see [Section 24.3, MMC/SD/SDIO Integration](#), and [Section 24.2, MMC/SD/SDIO Environment](#).

**Table 24-21. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. See "module clocks enable programming model" in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Control module	Module-specific pad muxing and configuration must be set in the control module. See <a href="#">Chapter 18, Control Module</a> .
(optional) MPU INTC (or DSP INTC)	MPU INTC configuration must be done to enable the interrupts from the MMCHS module. See <a href="#">Chapter 17, Interrupt Controllers</a> .
(optional) sDMA (or dDMA)	DMA configuration must be done to enable the module DMA channel requests. See <a href="#">Chapter 16, SDMA</a> .
(optional) Interconnect	For more information about the interconnect configuration, see <a href="#">Chapter 13, Interconnect</a> .

**NOTE:** The MPU/DSP INTC and the sDMA/dDMA configurations are necessary if the interrupt and DMA-based communication modes are used.

##### 24.5.1.1.2 MMC/SD/SDIO Host Controller Initialization Flow

[Table 24-22](#) shows the general boot process.

**Table 24-22. MMC/SD/SDIO Controller Meta Initialization Steps**

Step	Access Type	Register/Bit Field/Programming Model	Value
Initialize clocks.		See <a href="#">Section 24.5.1.1.2.1</a> .	
Software reset of the controller		See <a href="#">Section 24.5.1.1.2.2</a> .	
Set module hardware capabilities.		See <a href="#">Section 24.5.1.1.2.3</a> .	
Set module idle and wake-up modes.		See <a href="#">Section 24.5.1.1.2.4</a> .	

##### 24.5.1.1.2.1 Enable Interface and Functional clock for MMC Controller

Before any MMCHS register access the MMCHS interface clock and functional clock in the PRCM module registers must be enabled. See [Section 3.6.4.4, Clock Domain Module Attributes](#), in [Chapter 3, Power, Reset, and Clock Management](#).

##### 24.5.1.1.2.2 MMCHS Soft Reset Flow

[Figure 24-36](#) shows the soft reset process of the MMCHS controller.

Figure 24-36. MMC/SD/SDIO Controller Software Reset Flow

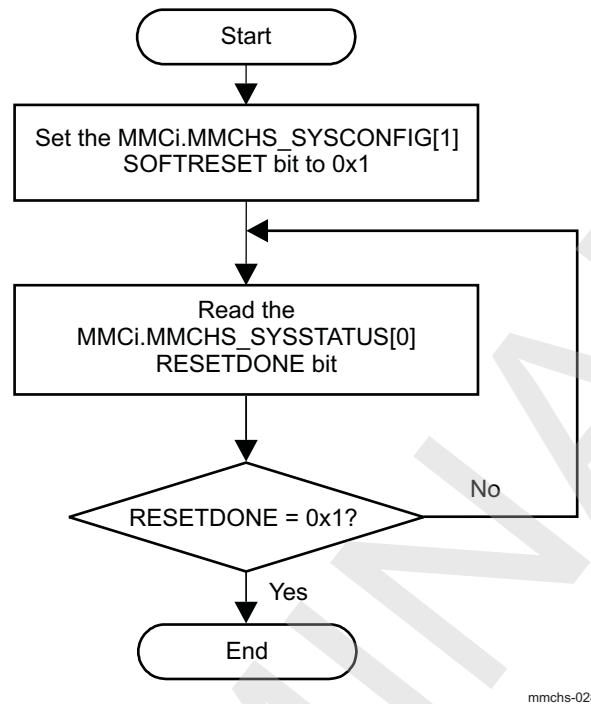

Table 24-23. Register Call Summary for Main Sequence – Software Reset Flow

Register Name	Register Name
MMCHS_SYSCONFIG	MMCHS_SYSSTATUS

24.5.1.1.2.3 Set MMCHS Default Capabilities

Software must read capabilities (in boot ROM, for example) and is allowed to set (write) the MMCi.MMCHS\_CAPA[26:24] and MMCi.MMCHS\_CUR\_CAPA[23:0] bit fields before the MMC/SD/SDIO host driver is started.

24.5.1.1.2.4 Wake-Up Configuration

Table 24-24 describes the MMCHS controller wake-up configuration.

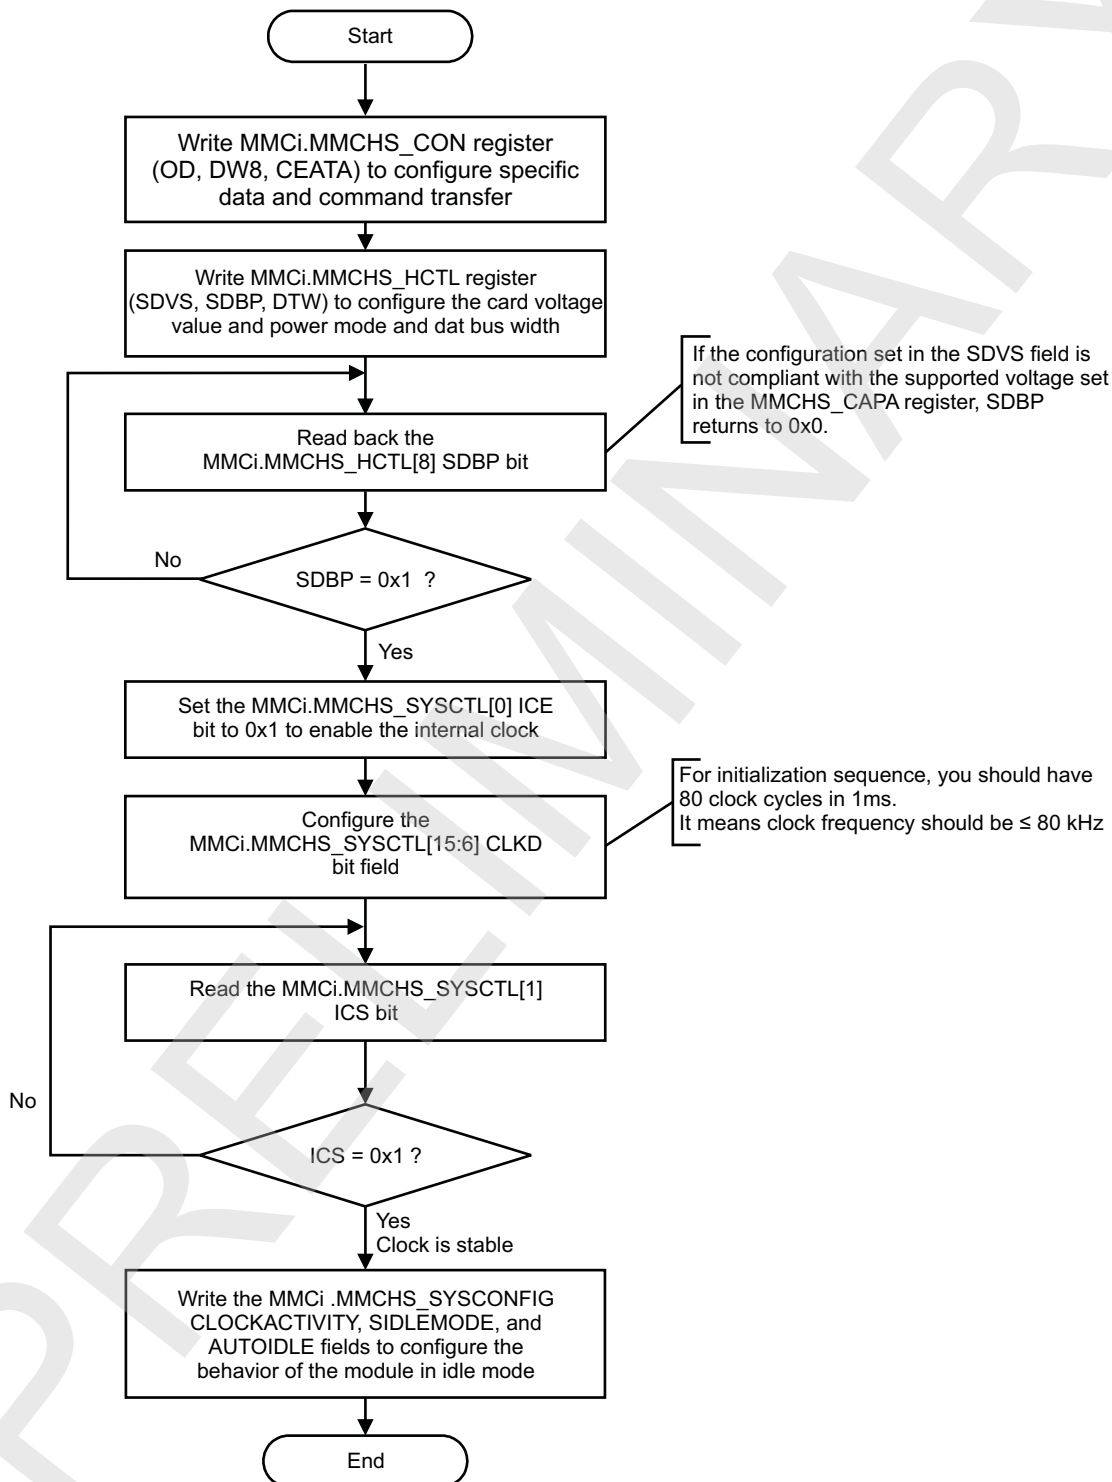

Table 24-24. MMC/SD/SDIO Controller Wake-Up Configuration

Step	Access Type	Register/Bit Field/Programming Model	Value
Configure wake-up bit (if necessary).	W	MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP	0x1
Enable wake-up events on SD card interrupt (if necessary).	W	MMCi.MMCHS_HCTL[24] IWE	0x1
<b>SDIO Card only:</b> Enable card interrupt (if necessary).	W	MMCi.MMCHS_IE[8] CIRQ_ENABLE	0x1

### 24.5.1.1.2.5 MMC Host and Bus Configuration

Figure 24-37 shows the MMC bus configuration process.

**Figure 24-37. MMC/SD/SDIO Controller Bus Configuration**

mmchs-029

**Table 24-25. Register Call Summary for Main Sequence – Bus Configuration**

Register Name	Register Name
MMCHS_CON	MMCHS_HCTL
MMCHS_SYSCONFIG	MMCHS_SYSCTL

### 24.5.1.2 Operational Modes Configuration

#### 24.5.1.2.1 Basic Operations for MMC/SD/SDIO Host Controller

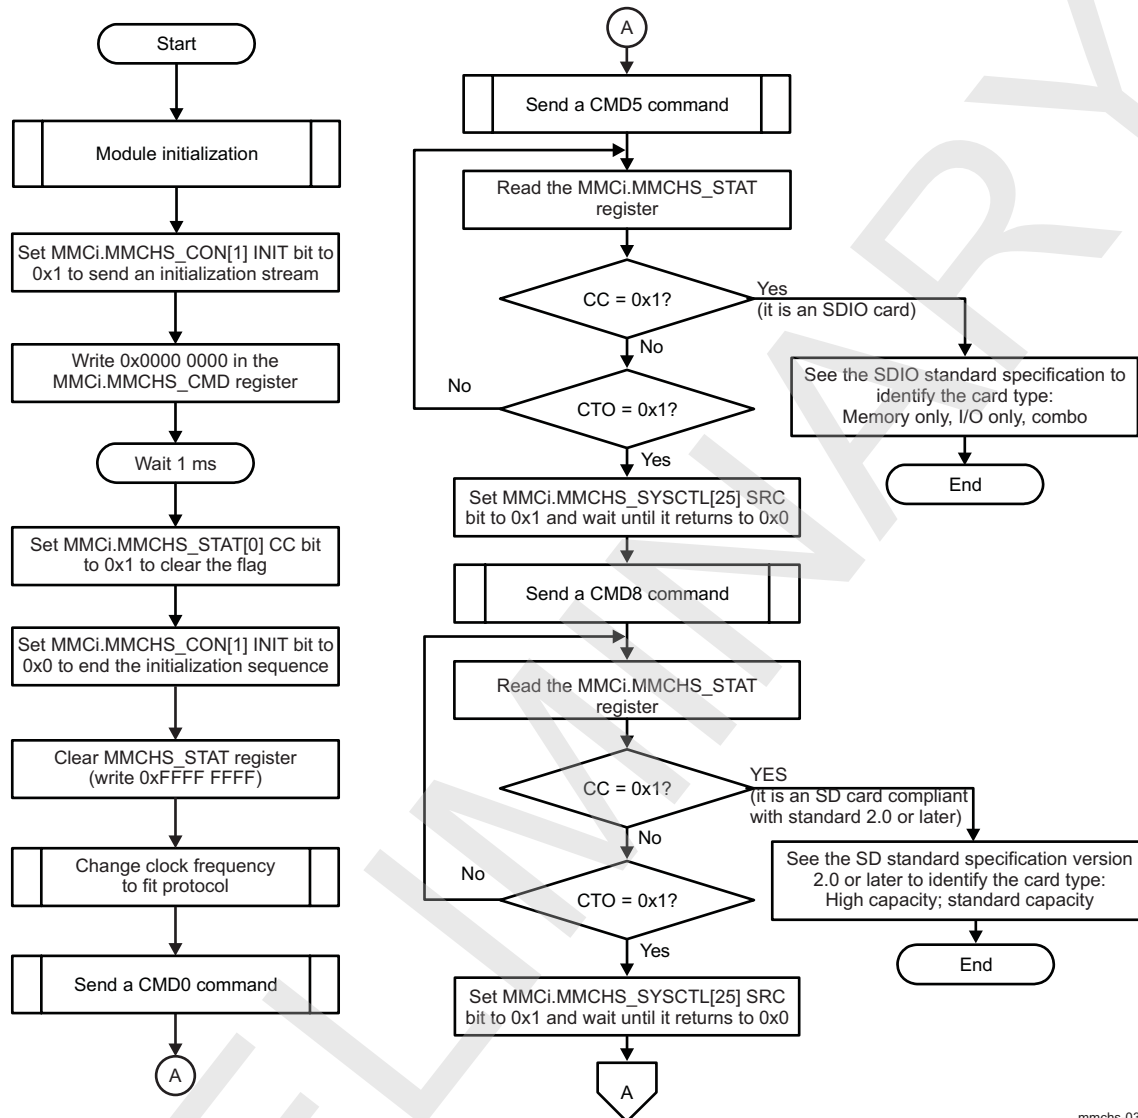

The MMC/SD/SDIO host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

##### 24.5.1.2.1.1 Card Detection, Identification, and Selection

[Figure 24-38](#) and [Figure 24-39](#) show the card identification and selection process.

Figure 24-38. MMC/SD/SDIO Controller Card Identification and Selection – Part 1

mmchs-030

**24.5.1.2.1.5 Read/Write Transfer Flow in CE-ATA Mode**

Figure 24-43 shows the read and write CE-ATA protocol when in polling mode.

**Figure 24-43. MMC/SD/SDIO Controller Read/Write in CE-ATA Mode**

**Table 24-34. Register Call Summary for Main Sequence – Read/Write in CE-ATA Mode**

Register Name	Register Name	Register Name
MMCHS_PSTATE	MMCHS_CON	MMCHS_IE
MMCHS_CMD	MMCHS_STAT	
MMCHS_ARG	MMCHS_SYSCTL	

**CAUTION**

CE-ATA protocol is supported only by MMC cards.

In CE-ATA mode, issuing a command during the transfer (except a CCSD command) is not allowed.

In CE-ATA mode, infinite transfers are not allowed; only finite transfers are permitted.

**24.5.1.2.1.6 Suspend-Resume Flow**

The suspend and resume feature is supported only by SDIO cards.

**24.5.1.2.1.6.1 Suspend Flow**

[Figure 24-44](#) shows the suspend flow for SDIO cards.

Send SWITCH command (CMD6).	Section 24.5.1.2.1.7.1

### 24.5.1.2.2 Bus Voltage Selection

The MMC/SD/SDIO1 controller can operate with two types of card voltages: 1.8 V and 3.0 V. For this reason, dual voltage pads are implemented on this interface. For technological concerns, those pads must have an internal bias voltage reference to operate. The PBIAS module supplies this bias voltage, depending on the CONTROL.CONTROL\_PBIAS\_LITE register settings.

For more information about the PBIAS\_LITE cell, see [Section 18.4.9](#), *Extended-Drain I/O and PBIAS Cell*, in [Chapter 18](#), *Control Module*.

For the steps involved in transitioning from 1.8 V to 3.0 V and from 3.0 V to 1.8 V, applicable to the MMC/SD/SDIO1 controller, see [Section 18.5.1.2.2](#), *Extended-Drain I/Os and PBIAS Cell Programming Guide*, in [Chapter 18](#), *Control Module*.

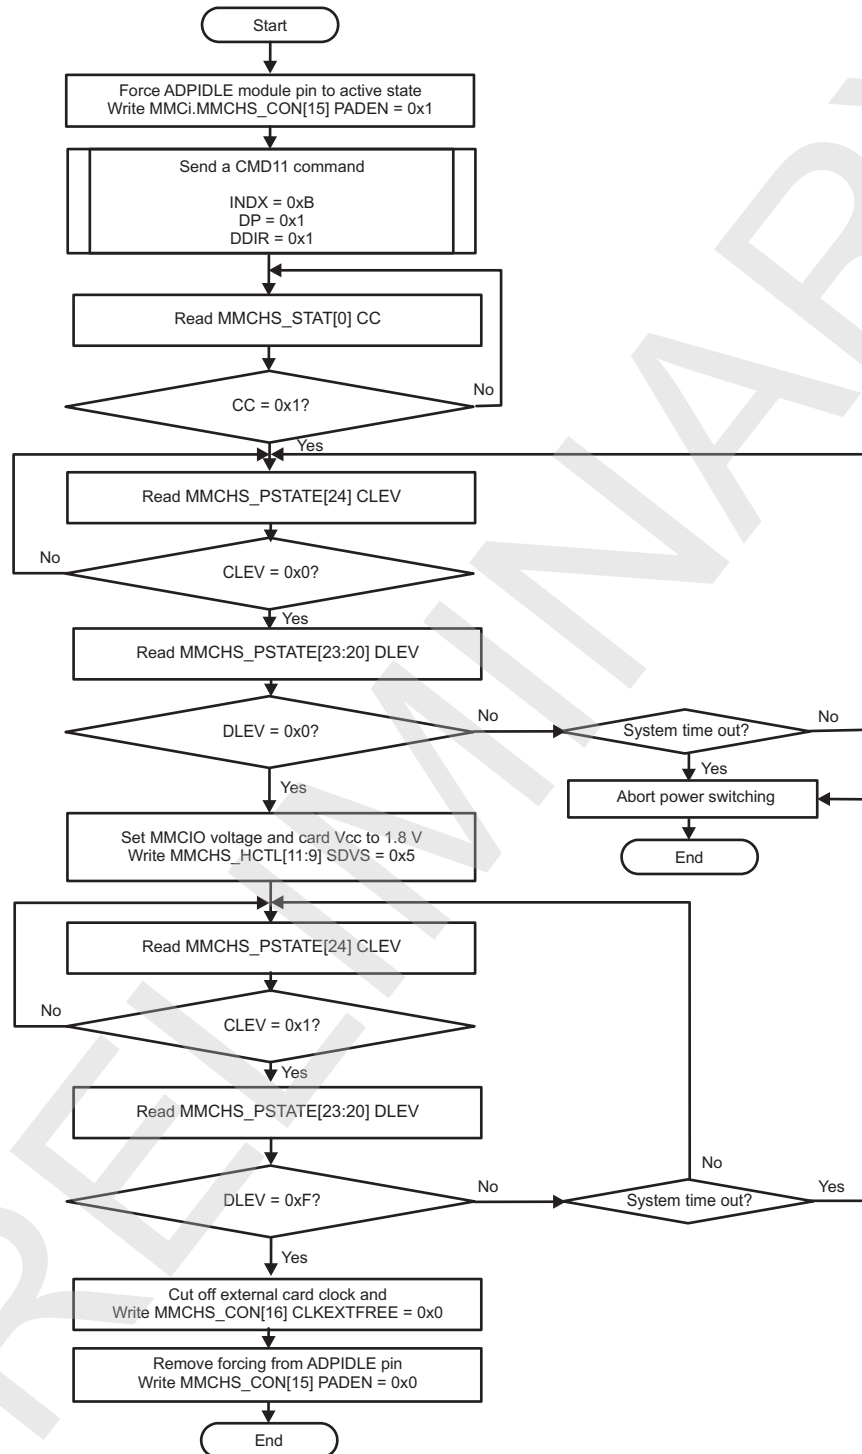

#### CAUTION

The BIAS voltage must be set using the procedure described in [Section 18.5.1.2.2](#), *Extended-Drain I/Os and PBIAS Cell Programming Guide*, in [Chapter 18](#), *Control Module*. Failure to follow this procedure can damage the MMCHS interface.

[Figure 24-50](#) shows how to configure the MMCHS controller to fit with power switching sequence.

Figure 24-50. MMC/SD/SDIO Power Switching Procedure

Subprocess Name	Cross-Reference
Send a READ_DAT_UNTIL_STOP command (CMD11).	<a href="#">Section 24.5.1.2.1.7.1</a>

### 24.5.1.2.3 Boot Mode Configuration

The following sections describe the two possible ways to issue a boot command: issue a CMD0 or drive the CMD line to 0 during the whole boot phase.

#### 24.5.1.2.3.1 Boot Using CMD0

Figure 24-51 shows the necessary steps to configure the controller boot mode using CMD0.

**Figure 24-51. MMC/SD/SDIO Controller Boot Using CMD0**

mmchs-043

To abort a boot sequence, the system must issue a CMD0 with [MMCHS\\_CMD\[23:22\]](#) CMD\_TYPE bit field set to 0x3 (the [MMCHS\\_CON\[17\]](#) BOOT\_ACK bit previously cleared to 0x0) during the transfer to abort the transfer and enable the card to exit from boot state.

**Table 24-46. Register Call Summary for Main Sequence – Boot Using CMD0**

Register Name	Register Name	Register Name
<a href="#">MMCHS_CON</a>	<a href="#">MMCHS_BLK</a>	<a href="#">MMCHS_SYSCTL</a>

**Table 24-47. Subprocess Call Summary for Main Sequence – Boot Using CMD0**

Subprocess Name	Cross-Reference
Send a CMD0 command.	<a href="#">Section 24.5.1.2.1.7.1</a>

### 24.5.1.2.3.2 Boot With CMD Line Tied to 0

Figure 24-52 shows the necessary steps to configure the controller in this mode; the driver must follow this sequence.

**Figure 24-52. MMC/SD/SDIO Controller Boot With CMD Line Tied to 0**

mmchs-044

To abort the boot sequence, the system must clear the [MMCHS\\_CON\[18\] BOOT\\_CF0](#) bit to 0x0 during the transfer to abort the transfer and enable the card to exit from boot state.

**Table 24-48. Register Call Summary for Main Sequence – Boot Using CMD0**

<b>Address Offset</b>	0x0000 0110	<b>Instance</b>	MMCHS
<b>Physical Address</b>	See <a href="#">Table 24-51</a> to <a href="#">Table 24-52</a>		
<b>Description</b>	System Configuration Register This register allows controlling various parameters of the Interconnect interface.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																STANDBYMODE	RESERVED	CLOCKACTIVITY	RESERVED	RESERVED	RESERVED	SIDLEMODE	ENAWAKEUP	SOFTRESET	AUTOIDLE						

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Reserved These bits are initialized to zero, and writes to them are ignored. Reads return 0.	R	0x00000
13:12	STANDBYMODE	Master interface power Management, standby/wait control. The bit field is only useful when generic parameter <a href="#">MMCHS_HL_HWINFO[0] MADMA_EN</a> (Master ADMA enable) is set as active, otherwise it is a read only register read a 0. 0x0: Force-standby. Mstandby is forced unconditionally. 0x1: No-standby. Mstandby is never asserted. 0x2: Smart-standby mode: local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. IP module shall not generate (initiator-related) wakeup events. 0x3: Smart-Standby wakeup-capable mode: local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. IP module may generate (master-related) wakeup events when in standby state. Mode is only relevant if the appropriate IP module "mwakeup" output is implemented.	RW	0x0
11:10	RESERVED	Reserved These bits are initialized to zero, and writes to them are ignored. Reads return 0.	R	0x0

Bits	Field Name	Description	Type	Reset
9:8	CLOCKACTIVITY	<p>Clocks activity during wake up mode period.</p> <p>Bit8: Interface clock Bit9: Functional clock</p> <p>0x0: Interface and Functional clock may be switched off. 0x1: Interface clock is maintained. Functional clock may be switched-off. 0x2: Functional clock is maintained. Interface clock may be switched-off. 0x3: Interface and Functional clocks are maintained.</p>	RW	0x0
7	RESERVED	<p>Reserved This bit is initialized to zero, and writes to it are ignored. Reads return 0.</p>	R	0
6	RESERVED	<p>Reserved - EmuSoft not supported This bit is initialized to zero, and writes to it are ignored. Reads return 0.</p>	R	0
5	RESERVED	<p>Reserved - EmuFree not supported This bit is initialized to zero, and writes to it are ignored. Reads return 0.</p>	R	0
4:3	SIDLEMODE	<p>Power management</p> <p>0x0: If an idle request is detected, the MMCHS acknowledges it unconditionally and goes in Inactive mode. Interrupt and DMA requests are unconditionally de-asserted. 0x1: If an idle request is detected, the request is ignored and the module keeps on behaving normally. 0x2: Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wakeup events. 0x3: Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state. Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented.</p>	RW	0x2
2	ENAWAKEUP	<p>Wakeup feature control</p> <p>0x0: Wakeup capability is disabled 0x1: Wakeup capability is enabled</p>	RW	1
1	SOFTRESET	<p>Software reset. The bit is automatically reset by the hardware. During reset, it always returns 0.</p> <p>Read 0x0: Normal mode Write 0x0: No effect. Write 0x1: Trigger a module reset. Read 0x1: The module is reset.</p>	RW	0
0	AUTOIDLE	<p>Internal Clock gating strategy</p> <p>0x0: Clocks are free-running 0x1: Automatic clock gating strategy is applied, based on the Interconnect and MMC interface activity</p>	RW	1

<b>Address Offset</b>	0x0000 0128		
<b>Physical Address</b>	See <a href="#">Table 24-51</a> to <a href="#">Table 24-52</a>	<b>Instance</b>	MMCHS
<b>Description</b>	<p>System Test register</p> <p>This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification.</p> <p>Note: In SYSTEST mode, a write into <a href="#">MMCHS_CMD</a> register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (<a href="#">MMCHS_BLK[11:0]</a> BLEN) and the Blocks count for current transfer (<a href="#">MMCHS_BLK[31:16]</a> NBLK) are needed to generate a Buffer write ready interrupt (<a href="#">MMCHS_STAT[4]</a> BWR) or a Buffer read ready interrupt (<a href="#">MMCHS_STAT[5]</a> BRR) and DMA requests if enabled.</p>		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31:22	RESERVED	Reserved These bits are initialized to zero, and writes to them are ignored. Reads return 0.	R	0x000
21	SDMA_LNE	Slave DMA Level/Edge Request: The waveform of the DMA request can be configured either edge sensitive with early de-assertion on first access to <a href="#">MMCHS_DATA</a> register or late de-assertion, request remains active until last allowed data written into <a href="#">MMCHS_DATA</a> .  0x0: Slave DMA edge sensitive, Early DMA de-assertion 0x1: Slave DMA level sensitive, Late DMA de-assertion	RW	0
20	DMA_MNS	DMA Master or Slave selection: When this bit is set and the controller is configured to use the DMA, Interconnect master interface is used to get datas from system using ADMA2 procedure (direct access to the memory). This option is only available if generic parameter <a href="#">MMCHS_HL_HWINFO[0]</a> <a href="#">MADMA_EN</a> is asserted to 1.  0x0: The controller is slave on data transfers with system. 0x1: The controller is master on data exchange with system, controller must be configured as using DMA.	RW	0
19	DDR	Dual Data Rate mode: When this register is set, the controller uses both clock edge to emit or receive data. Odd bytes are transmitted on falling edges and even bytes are transmitted on rise edges. It only applies on Data bytes and CRC, Start, end bits and CRC status are kept full cycle. This bit field is only meaningful and active for even clock divider ratio of <a href="#">MMCHS_SYSCTL[15:6]</a> <a href="#">CLKD</a> , it is insensitive to <a href="#">MMCHS_HCTL[2]</a> <a href="#">HSPE</a> setting.  0x0: Standard mode : data are transmitted on a single edge depending on <a href="#">MMCHS_HCTL[2]</a> <a href="#">HSPE</a> . 0x1: Data Bytes and CRC are transmitted on both edge.	RW	0
18	BOOT_CFO	Boot status supported: This register is set when the CMD line need to be forced to 0 for a boot sequence. CMD line is driven to 0 after writing in <a href="#">MMCHS_CMD</a> . The line is released when this bit field is de-asserted and abort data transfer in case of a pending transaction.  Write 0x0: CMD line is released when it was previously forced to 0 by a boot sequence. Read 0x0: CMD line not forced Read 0x1: CMD line forced to 0 is enabled Write 0x1: CMD line forced to 0 is enabled and will be active after writing into <a href="#">MMCHS_CMD</a>	RW	0
17	BOOT_ACK	Book acknowledge received: When this bit is set the controller should receive a boot status on DAT0 line after next command issued. If no status is received a data timeout will be generated.  0x0: No acknowledge to be received 0x1: A boot status will be received on DAT0 line after issuing a command.	RW	0

Bits	Field Name	Description	Type	Reset
16	CLKEXTFREE	<p>External clock free running: This register is used to maintain card clock out of transfer transaction to enable slave module for example to generate a synchronous interrupt on DAT[1]. The Clock will be maintain only if <a href="#">MMCHS_SYSCTL[2]</a> CEN is set.</p> <p>0x0: External card clock is cut off outside active transaction period.</p> <p>0x1: External card clock is maintain even out of active transaction period only if <a href="#">MMCHS_SYSCTL[2]</a> CEN is set.</p>	RW	0
15	PADEN	<p>Control Power for MMC Lines: This register is only useful when MMC PADS contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADS. Excepted for DAT[1], the signal is also combine outside the module with the dedicated power control <a href="#">MMCHS_CON[11]</a> CTPL bit.</p> <p>0x0: ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms.</p> <p>0x1: ADPIDLE module pin is forced to active state.</p>	RW	0
14	OBIE	<p>Out-of-Band Interrupt Enable MMC cards only: This bit enables the detection of Out-of-Band Interrupt on MMCOBI input pin. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration.</p> <p>0x0: Out-of-Band interrupt detection disabled</p> <p>0x1: Out-of-Band interrupt detection enabled</p>	RW	0
13	OBIP	<p>Out-of-Band Interrupt Polarity MMC cards only: This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration.</p> <p>0x0: active high level</p> <p>0x1: active low level</p>	RW	0
12	CEATA	<p>CE-ATA control mode MMC cards compliant with CE-ATA:By default, this bit is set to 0. It is use to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features.</p> <p>0x0: Standard MMC/SD/SDIO mode.</p> <p>0x1: CE-ATA mode next commands are considered as CE-ATA commands.</p>	RW	0
11	CTPL	<p>Control Power for DAT[1] line MMC and SD cards: By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current. SDIO cards: When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of DAT[1] outside of a transaction in order to detect asynchronous card interrupt on DAT[1] line and minimize the leakage current of the buffers.</p> <p>0x0: Disable all the input buffers outside of a transaction.</p> <p>0x1: Disable all the input buffers except the buffer of DAT[1] outside of a transaction.</p>	RW	0

Bits	Field Name	Description	Type	Reset
10:9	DVAL	<p>Debounce filter value All cards This register is used to define a debounce period to filter the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card.</p> <p>0x0: 33 us debounce period 0x1: 231 us debounce period 0x2: 1 ms debounce period 0x3: 8,4 ms debounce period</p>	RW	0x3
8	WPP	<p>Write protect polarity For SD and SDIO cards only This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card.</p> <p>0x0: active high level 0x1: active low level</p>	RW	0
7	CDP	<p>Card detect polarity All cards This bit selects the active level of the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card.</p> <p>0x0: active high level 0x1: active low level</p>	RW	0
6	MIT	<p>MMC interrupt command Only for MMC cards. This bit must be set to 1, when the next write access to the command register (<a href="#">MMCHS_CMD</a>) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response.</p> <p>0x0: Command timeout enabled 0x1: Command timeout disabled</p>	RW	0
5	DW8	<p>8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification 4.x (see section 3.6).</p> <p>0x0: 1-bit or 4-bit Data width (DAT[0] used, MMC, SD cards) 0x1: 8-bit Data width (DAT[7:0] used, MMC cards)</p>	RW	0

Bits	Field Name	Description	Type	Reset
4	MODE	<p>Mode select All cards These bits select between Functional mode and SYSTEST mode.</p> <p>0x0: Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. MMC clock is enabled. MMC/SD transfers are operated under the control of the CMD register.</p> <p>0x1: SYSTEST mode The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.</p>	RW	0
3	STR	<p>Stream command Only for MMC cards. This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11: READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20: WRITE_DAT_UNTIL_STOP).</p> <p>0x0: Block oriented data transfer 0x1: Stream oriented data transfer</p>	RW	0
2	HR	<p>Broadcast host response Only for MMC cards. This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core (see section 4.3, "Interrupt Mode", in the MMC [1] specification). In order to have the host response to be generated in open drain mode, the register <a href="#">MMCHS_CON[0]</a> OD must be set to 1. When <a href="#">MMCHS_CON[12]</a> CEATA is set to 1 and <a href="#">MMCHS_ARG</a> set to 0x00000000 when writing 0x00000000 into <a href="#">MMCHS_CMD</a> register, the host controller performs a 'command completion signal disable' token that is, CMD line held to 0 during 47 cycles followed by a 1.</p> <p>0x0: The host does not generate a 48-bit response instead of a command. 0x1: The host generates a 48-bit response instead of a command or a command completion signal disable token.</p>	RW	0
1	INIT	<p>Send initialization stream All cards. When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the CMD line to 1 during 80 clock cycles. The initialisation sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (<a href="#">MMCHS_SYSCTL[15:6]</a> CLKD) should be set to ensure that 80 clock periods are greater than 1ms. (see section 9.3, "Power-Up", in the MMC card specification [1], or section 6.4 in the SD card specification [2]). Note: in this mode, there is no command sent to the card and no response is expected</p> <p>0x0: The host does not send an initialization sequence. 0x1: The host sends an initialization sequence.</p>	RW	0

Bits	Field Name	Description	Type	Reset
0	OD	<p>Card open drain mode. Only for MMC cards. This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register <a href="#">MMCHS_CON[2]</a> HR)</p> <p>0x0: No Open Drain 0x1: Open Drain or Broadcast host response</p>	RW	0

23:22	CMD_TYPE	Command type This register specifies three types of special command: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. 0x0: Others Commands 0x1: CMD52 for writing "Bus Suspend" in CCCR 0x2: CMD52 for writing "Function Select" in CCCR 0x3: Abort command CMD12, CMD52 for writing " I/O Abort" in CCCR	RW	0x0
21	DP	Data present select This register indicates that data is present and DAT line shall be used. It must be set to 0 in the following conditions: - command using only CMD line - command with no data transfer but using busy signal on DAT[0] - Resume command 0x0: Command with no data transfer 0x1: Command with data transfer	RW	0
20	CICE	Command Index check enable This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error ( <a href="#">MMCHS_STAT[19]</a> CIE set to 1) Note: The register CICE cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. 0x0: Index check disable 0x1: Index check enable	RW	0
19	CCCE	Command CRC check enable This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error ( <a href="#">MMCHS_STAT[17]</a> CCRC set to 1). Note: The register CCCE cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued. 0x0: CRC7 check disable 0x1: CRC7 check enable	RW	0
18	RESERVED	Reserved. This bit is initialized to zero, and writes to it are ignored.	R	0

Bits	Field Name	Description	Type	Reset
17:16	RSP_TYPE	Response type This bits defines the response type of the command 0x0: No response 0x1: Response Length 136 bits 0x2: Response Length 48 bits 0x3: Response Length 48 bits with busy after response	RW	0x0
15:6	RESERVED	Reserved. These bits are initialized to zero, and writes to them are ignored.	R	0x000
5	MSBS	Multi/Single block select This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be set to 0. 0x0: Single block. If this bit is 0, it is not necessary to set the register <a href="#">MMCHS_BLK[31:16]</a> NBLK. 0x1: Multi block. When Block Count is disabled ( <a href="#">MMCHS_CMD[1]</a> BCE is set to 0) in Multiple block transfers ( <a href="#">MMCHS_CMD[5]</a> MSBS is set to 1), the module can perform infinite transfer.	RW	0
4	DDIR	Data transfer Direction Select This bit defines either data transfer will be a read or a write. 0x0: Data Write (host to card) 0x1: Data Read (card to host)	RW	0
3	RESERVED	Reserved. These bits are initialized to zero, and writes to them are ignored.	R	0
2	ACEN	Auto CMD12 Enable SD card only. When this bit is set to 1, the host controller issues a CMD12 automatically after the transfer completion of the last block. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop data transfer. In particular, safe commands do not require CMD12. 0x0: Auto CMD12 disable 0x1: Auto CMD12 enable or CCS detection enabled.	RW	0
1	BCE	Block Count Enable Multiple block transfers only. This bit is used to enable the block count register ( <a href="#">MMCHS_BLK[31:16]</a> NBLK). When Block Count is disabled ( <a href="#">MMCHS_CMD[1]</a> BCE is set to 0) in Multiple block transfers ( <a href="#">MMCHS_CMD[5]</a> MSBS is set to 1), the module can perform infinite transfer. 0x0: Block count disabled for infinite transfer. 0x1: Block count enabled for multiple block transfer with known number of blocks	RW	0
0	DE	DMA Enable This bit is used to enable DMA mode for host data access. 0x0: DMA mode disable 0x1: DMA mode enable	RW	0

<b>Address Offset</b>	0x0000 0220	<b>Instance</b>	MMCHS
<b>Physical Address</b>	See <a href="#">Table 24-51</a> to <a href="#">Table 24-52</a>		
<b>Description</b>	<p>Data Register</p> <p>This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput.</p> <p>Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer.</p> <p>Example 1: Byte or 16-bit access  Mbyteen[3:0]=0001 (1-byte) =&gt; Mbyteen[3:0]=0010 (1-byte) =&gt; Mbyteen[3:0]=1100 (2-bytes) OK  Mbyteen[3:0]=0001 (1-byte) =&gt; Mbyteen[3:0]=0010 (1-byte) =&gt; Mbyteen[3:0]=0100 (1-byte) OK  Mbyteen[3:0]=0001 (1-byte) =&gt; Mbyteen[3:0]=0010 (1-byte) =&gt; Mbyteen[3:0]=1000 (1-byte) Bad</p>		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA																															

Bits	Field Name	Description	Type	Reset
31:0	DATA	Data Register [31:0] In functional mode ( <a href="#">MMCHS_CON[4] MODE</a> set to the default value 0) , A read access to this register is allowed only when the buffer read enable status is set to 1 ( <a href="#">MMCHS_PSTATE[11] BRE</a> ), otherwise a bad access ( <a href="#">MMCHS_STAT[29] BADA</a> ) is signaled. A write access to this register is allowed only when the buffer write enable status is set to 1( <a href="#">MMCHS_PSTATE[10] BWE</a> ), otherwise a bad access ( <a href="#">MMCHS_STAT[29] BADA</a> ) is signaled and the data is not written. <b>Description</b>	Present state register The Host can get status of the Host Controller from this 32-bit read only register.		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								CLEV	DLEV			WP	CDPL	CSS	CINS	RESERVED					BRE	BWE	RTA	WTA	RESERVED				DLA	DATI	CMDI

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Reserved. These bits are initialized to zero, and writes to them are ignored.	R	0x00
24	CLEV	CMD line signal level This status is used to check the CMD line level to recover from errors, and for debugging. The value of this register after reset depends on the CMD line level at that time. Read 0x0: The CMD line level is 0. Read 0x1: The CMD line level is 1.	R	-
23:20	DLEV	DAT[3:0] line signal level DAT[3] => bit 23 DAT[2] => bit 22 DAT[1] => bit 21 DAT[0] => bit 20 This status is used to check DAT line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DAT[0]. The value of these registers after reset depends on the DAT lines level at that time.	R	0x-

Bits	Field Name	Description	Type	Reset
19	WP	<p>Write protect switch pin level For SDIO cards only. This bit reflects the write protect input pin (SDWP) level. The value of this register after reset depends on the protect input pin (SDWP) level at that time.</p> <p>Read 0x0: If <a href="#">MMCHS_CON[8]</a> WPP is set to 0 (default), the card is write protected, otherwise the card is not protected.</p> <p>Read 0x1: If <a href="#">MMCHS_CON[8]</a> WPP is set to 0 (default), the card is not write protected, otherwise the card is protected.</p>	R	-
18	CDPL	<p>Card detect pin level This bit reflects the inverse value of the card detect input pin (SDCD), debouncing is not performed on this bit and bit is valid only when Card State Stable (<a href="#">MMCHS_PSTATE[17]</a> CSS) is set to 1. Use of this bit is limited to testing since it must be debounced by software. The value of this register after reset depends on the card detect input pin (SDCD) level at that time.</p> <p>Read 0x0: The value of the card detect input pin (SDCD) is 1</p> <p>Read 0x1: The value of the card detect input pin (SDCD) is 0</p>	R	-
17	CSS	<p>Card State Stable This bit is used for testing. It is set to 1 only when Card Detect Pin Level is stable (<a href="#">MMCHS_PSTATE[18]</a> CDPL). Debouncing is performed on the card detect input pin (SDCD) to detect card stability. This bit is not affected by a software reset.</p> <p>Read 0x0: Reset or Debouncing</p> <p>Read 0x1: No card or card inserted</p>	R	0
16	CINS	<p>Card inserted This bit is the debounced value of the card detect input pin (SDCD). An inactive to active transition of the card detect input pin (SDCD) will generate a card insertion interrupt (<a href="#">MMCHS_STAT[6]</a> CINS). A active to inactive transition of the card detect input pin (SDCD) will generate a card removal interrupt (<a href="#">MMCHS_STAT[7]</a> CREM). This bit is not affected by a software reset.</p> <p>Read 0x0: If <a href="#">MMCHS_CON[7]</a> CDP is set to 0 (default), no card is detected. The card may have been removed from the card slot. If <a href="#">MMCHS_CON[7]</a> CDP is set to 1, the card has been inserted.</p> <p>Read 0x1: If <a href="#">MMCHS_CON[7]</a> CDP is set to 0 (default), the card has been inserted from the card slot. If <a href="#">MMCHS_CON[7]</a> CDP is set to 1, no card is detected. The card may have been removed from the card slot.</p>	R	0
15:12	RESERVED	<p>Reserved. These bits are initialized to zero, and writes to them are ignored.</p>	R	0x0

Bits	Field Name	Description	Type	Reset
11	BRE	<p>Buffer read enable This bit is used for non-DMA read transfers. It indicates that a complete block specified by <a href="#">MMCHS_BLK[11:0]</a> BLEN has been written in the buffer and is ready to be read. It is set to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (<a href="#">MMCHS_STAT[5]</a> BRR).</p> <p>Read 0x0: Read BLEN bytes disable Read 0x1: Read BLEN bytes enable. Readable data exists in the buffer.</p>	R	0
10	BWE	<p>Buffer Write enable This status is used for non-DMA write transfers. It indicates if space is available for write data.</p> <p>Read 0x0: There is no room left in the buffer to write BLEN bytes of data. Read 0x1: There is enough space in the buffer to write BLEN bytes of data.</p>	R	0
9	RTA	<p>Read transfer active This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (<a href="#">MMCHS_HCTL[17]</a> CR) following a stop at block gap request. This bit is set to 0 when all data have been read by the local host after last block or after a stop at block gap request.</p> <p>Read 0x0: No valid data on the DAT lines. Read 0x1: read data transfer on going.</p>	R	0
8	WTA	<p>Write transfer active This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (<a href="#">MMCHS_HCTL[17]</a> CR) following a stop at block gap request. This bit is set to 0 when CRC status has been received after last block or after a stop at block gap request.</p> <p>Read 0x0: No valid data on the DAT lines. Read 0x1: Write data transfer on going.</p>	R	0
7:3	RESERVED	<p>Reserved. These bits are initialized to zero, and writes to them are ignored.</p>	R	0x00
2	DLA	<p>DAT line active This status bit indicates whether one of the DAT line is in use. In the case of read transactions (card to host): This bit is set to 1 after the end bit of read command or by activating continue request <a href="#">MMCHS_HCTL[17]</a> CR. This bit is set to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card): This bit is set to 1 after the end bit of write command or by activating continue request <a href="#">MMCHS_HCTL[17]</a> CR. This bit is set to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request.</p> <p>Read 0x0: DAT Line inactive Read 0x1: DAT Line active</p>	R	0

Bits	Field Name	Description	Type	Reset
1	DATI	<p>Command inhibit(DAT)</p> <p>This status bit is generated if either DAT line is active (<a href="#">MMCHS_PSTATE[2]</a> DLA) or Read transfer is active (<a href="#">MMCHS_PSTATE[9]</a> RTA) or when a command with busy is issued. This bit prevents the local host to issue a command.</p> <p>A change of this bit from 1 to 0 generates a transfer complete interrupt (<a href="#">MMCHS_STAT[1]</a> TC).</p> <p>Read 0x0: Issuing of command using the DAT lines is allowed</p> <p>Read 0x1: Issuing of command using DAT lines is not allowed</p>	R	0
0	CMDI	<p>Command inhibit(CMD)</p> <p>This status bit indicates that the CMD line is in use. This bit is set to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted.</p> <p>This bit is set to 0 in either the following cases:</p> <ul style="list-style-type: none"> <li>- After the end bit of the command response, excepted if there is a command conflict error (<a href="#">MMCHS_STAT[17]</a> CCRC or <a href="#">MMCHS_STAT[18]</a> CEB set to 1) or a Auto CMD12 is not executed (<a href="#">MMCHS_AC12[0]</a> ACNE).</li> <li>- After the end bit of the command without response (<a href="#">MMCHS_CMD[17:16]</a> RSP_TYPE set to "00")</li> </ul> <p>In case of a command data error is detected (<a href="#">MMCHS_STAT[16]</a> CTO set to 1), this register is not automatically cleared.</p> <p>Read 0x0: Issuing of command using CMD line is allowed</p> <p>Read 0x1: Issuing of command using CMD line is not allowed</p>	R	0

23:20	RESERVED	Reserved. These bits are initialized to zero, and writes to them are ignored.	R	0x0

Bits	Field Name	Description	Type	Reset
19	IBG	<p>Interrupt block at gap</p> <p>This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be set to 0.</p> <p>0x0: Disable interrupt detection at the block gap in 4-bit mode</p> <p>0x1: Enable interrupt detection at the block gap in 4-bit mode</p>	RW	0
18	RWC	<p>Read wait control</p> <p>The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (<a href="#">MMCHS_HCTL[16]</a> SBGR) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on DAT line.</p> <p>0x0: Disable Read Wait Control. Suspend/Resume cannot be supported.</p> <p>0x1: Enable Read Wait Control</p>	RW	0
17	CR	<p>Continue request</p> <p>This bit is used to restart a transaction that was stopped by requesting a stop at block gap (<a href="#">MMCHS_HCTL[16]</a> SBGR). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted i.e DAT line is active (<a href="#">MMCHS_PSTATE[2]</a> DLA) or transferring data (<a href="#">MMCHS_PSTATE[8]</a> WTA). The Stop at block gap request must be disabled (<a href="#">MMCHS_HCTL[16]</a> SBGR = 0) before setting this bit.</p> <p>0x0: No affect</p> <p>0x1: transfer restart</p>	RW	0
16	SBGR	<p>Stop at block gap request</p> <p>This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (<a href="#">MMCHS_HCTL[17]</a> CR) or during a suspend/resume sequence.</p> <p>In case of read transfer, the card must support read wait control.</p> <p>In case of write transfer, the host driver shall set this bit after all block data written.</p> <p>Until the transfer completion (<a href="#">MMCHS_STAT[1]</a> TC set to 1), the host driver shall leave this bit set to 1.</p> <p>If this bit is set, the local host shall not write to the data register (<a href="#">MMCHS_DATA</a>).</p> <p>0x0: Transfer mode</p> <p>0x1: Stop at block gap</p>	RW	0
15:12	RESERVED	<p>Reserved.</p> <p>These bits are initialized to zero, and writes to them are ignored.</p>	R	0x0
11:9	SDVS	<p>SD bus voltage select</p> <p>All cards.</p> <p>The host driver should set to these bits to select the voltage level for the card according to the voltage supported by the system (<a href="#">MMCHS_CAPA[26:24]</a>) before starting a transfer.</p> <p>0x5: 1.8V (Typical)</p> <p>0x6: 3.0V (Typical)</p> <p>0x7: 3.3V (Typical)</p>	RW	0x0

Bits	Field Name	Description	Type	Reset
8	SDBP	<p>SD bus power</p> <p>Before setting this bit, the host driver shall select the SD bus voltage (<a href="#">MMCHS_HCTL[11:9] SDVS</a>). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register (<a href="#">MMCHS_CMD</a>) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage is not supported according to capability register (<a href="#">MMCHS_CAPA[26:24]</a>).</p> <p>0x0: Power off</p> <p>0x1: Power on</p>	RW	0
7	CDSS	<p>Card Detect Signal Selection</p> <p>This bit selects source for the card detection. When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupt being caused by the glitch. The Interrupt Status/Signal Enable should be disabled during over the period of debouncing.</p> <p>0x0: SDCD# is selected (for normal use)</p> <p>0x1: The Card Detect Test Level is selected (for test purpose)</p>	RW	0
6	CDTL	<p>Card Detect Test Level:</p> <p>This bit is enabled while the Card Detect Signal Selection is set to 1 and it indicates card inserted or not.</p> <p>0x0: No Card</p> <p>0x1: Card Inserted</p>	RW	0
5	RESERVED	<p>Reserved.</p> <p>These bits are initialized to zero, and writes to them are ignored.</p>	R	0
4:3	DMAS	<p>DMA Select Mode:</p> <p>One of supported DMA modes can be selected. The host driver shall check support of DMA modes by referring the Capabilities register. Use of selected DMA is determined by DMA Enable of the Transfer Mode register. This register is only meaningful when <a href="#">MMCHS_HL_HWINFO[0] MADMA_EN</a> is set to 1. When <a href="#">MMCHS_HL_HWINFO[0] MADMA_EN</a> is set to 0 the bit field is read only and returned value is 0.</p> <p>0x0: Reserved</p> <p>0x1: Reserved</p> <p>0x2: 32-bit Address ADMA2 is selected</p> <p>0x3: Reserved</p>	RW	0x0
2	HSPE	<p>High Speed Enable:</p> <p>Before setting this bit, the Host Driver shall check the High Speed Support in the Capabilities register. If this bit is set to 0 (default), the Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock. If this bit is set to 1, the Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock. This bit shall not be set when dual data rate mode is activated in <a href="#">MMCHS_CON[19] DDR</a>.</p> <p>0x0: Normal speed mode</p> <p>0x1: High speed mode</p>	RW	0

Bits	Field Name	Description	Type	Reset
1	DTW	<p>Data transfer width</p> <p>For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliance with MMC standard specification 4.x (see section 3.6).</p> <p>This register has no effect when the MMC 8-bit mode is selected (register <a href="#">MMCHS_CON[5]</a> DW8 set to 1 ),</p> <p>For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card.</p> <p>0x0: 1-bit Data width (DAT[0] used)</p> <p>0x1: 4-bit Data width (DAT[3:0] used)</p>	RW	0
0	LED	<p>Reserved bit.</p> <p>LED control feature is not supported</p> <p>This bit is initialized to zero, and writes to it are ignored.</p>	R	0

16	CTO	<p>Command Timeout Error</p> <p>This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: No error</p> <p>Read 0x1: Time Out</p> <p>Write 0x1: Status is cleared</p>	RW	0
15	ERRI	<p>Error Interrupt</p> <p>If any of the bits in the Error Interrupt Status register (<a href="#">MMCHS_STAT[24:15]</a>) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored.</p> <p>Read 0x0: No Interrupt.</p> <p>Read 0x1: Error interrupt event(s) occurred</p>	R	0
14:11	RESERVED	<p>Reserved.</p> <p>These bits are initialized to zero, and writes to them are ignored.</p>	R	0x0

Bits	Field Name	Description	Type	Reset
10	BSR	<p>Boot status received interrupt This bit is set automatically when <a href="#">MMCHS_CON[18]</a> BOOT_CF0 is set 0x0 or 0x1 and a boot status is received on DAT[0] line. This interrupt is only useful for MMC card.</p> <p>Write 0x0: Status bit unchanged Read 0x0: No Interrupt. Write 0x1: Status is cleared Read 0x1: Boot status received interrupt.</p>	RW	0
9	OBI	<p>Out-Of-Band interrupt This bit is set automatically when <a href="#">MMCHS_CON[14]</a> OBIE is set and an Out-of-Band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by <a href="#">MMCHS_CON[13]</a> OBIP. This interrupt is only useful for MMC card. The Out-of-Band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation.</p> <p>Read 0x0: No Out-Of-Band interrupt. Write 0x0: Status bit unchanged Read 0x1: Interrupt Out-Of-Band occurs Write 0x1: Status is cleared</p>	RW	0
8	CIRQ	<p>Card interrupt This bit is only used for SD and SDIO and CE-ATA cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drives CMD line to zero during one cycle after data transmission end. All modes above are fully exclusive. The controller interrupt must be clear by setting <a href="#">MMCHS_IE[8]</a> CIRQ_ENABLE to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as <a href="#">MMCHS_IE[8]</a> CIRQ_ENABLE is set to 1. Writes to this bit are ignored.</p> <p>Read 0x0: No card interrupt Read 0x1: Generate card interrupt</p>	R	0
7	CREM	<p>Card removal This bit is set automatically when <a href="#">MMCHS_PSTATE[16]</a> CINS changes from 1 to 0. A clear of this bit doesn't affect Card inserted present state (<a href="#">MMCHS_PSTATE[16]</a> CINS).</p> <p>Write 0x0: Status bit unchanged Read 0x0: Card state stable or Debouncing Read 0x1: Card removed Write 0x1: Status is cleared</p>	RW	0
6	CINS	<p>Card insertion This bit is set automatically when <a href="#">MMCHS_PSTATE[16]</a> changes from 0 to 1. A clear of this bit doesn't affect Card inserted present state (<a href="#">MMCHS_PSTATE[16]</a> CINS).</p> <p>Read 0x0: Card state stable or debouncing Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Card inserted</p>	RW	0

Bits	Field Name	Description	Type	Reset
5	BRR	<p>Buffer read ready</p> <p>This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by <a href="#">MMCHS_BLK[11:0]</a> BLEN is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it. Note: If the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated.</p> <p>Read 0x0: Not Ready to read buffer</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Ready to read buffer</p> <p>Write 0x1: Status is cleared</p>	RW	0
4	BWR	<p>Buffer write ready</p> <p>This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by <a href="#">MMCHS_BLK[11:0]</a> BLEN. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer. Note: If the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: Not Ready to write buffer</p> <p>Read 0x1: Ready to write buffer</p> <p>Write 0x1: Status is cleared</p>	RW	0
3	DMA	<p>DMA interrupt :</p> <p>This status is set when an interrupt is required in the ADMA instruction and after the data transfer completion.</p> <p>Read 0x0: Dma interrupt detected</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: No dma interrupt</p>	RW	0
2	BGE	<p>Block gap event</p> <p>When a stop at block gap is requested (<a href="#">MMCHS_HCTL[16]</a> SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.</p> <p>This event does not occur when the stop at block gap is requested on the last block.</p> <p>In read mode, a 1-to-0 transition of the DAT Line active status (<a href="#">MMCHS_PSTATE[2]</a> DLA) between data blocks generates a Block gap event interrupt.</p> <p>Read 0x0: No block gap event</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Transaction stopped at block gap</p>	RW	0

Bits	Field Name	Description	Type	Reset
1	TC	<p>Transfer completed</p> <p>This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (<a href="#">MMCHS_HCTL[16]</a> SBGR).</p> <p>In Read mode: This bit is automatically set on completion of a read transfer (<a href="#">MMCHS_PSTATE[9]</a> RTA).</p> <p>In write mode: This bit is set automatically on completion of the DAT line use (<a href="#">MMCHS_PSTATE[2]</a> DLA).</p> <p>Write 0x0: Status bit unchanged Read 0x0: No transfer complete Write 0x1: Status is cleared Read 0x1: Data transfer complete</p>	RW	0
0	CC	<p>Command complete</p> <p>This bit is set when a 1-to-0 transition occurs in the register command inhibit (<a href="#">MMCHS_PSTATE[0]</a> CMDI)</p> <p>If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command.</p> <p>A command timeout error (<a href="#">MMCHS_STAT[16]</a> CTO) has higher priority than command complete (<a href="#">MMCHS_STAT[0]</a> CC).</p> <p>If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt.</p> <p>Write 0x0: Status bit unchanged Read 0x0: No Command complete Write 0x1: Status is cleared Read 0x1: Command complete</p>	RW	0

<b>Address Offset</b>	0x0000 023C	
<b>Physical Address</b>	See <a href="#">Table 24-51</a> to <a href="#">Table 24-52</a>	<b>Instance</b> MMCHS
<b>Description</b>	Auto CMD12 Error Status Register The host driver may determine which of the errors cases related to Auto CMD12 has occurred by checking this <a href="#">MMCHS_AC12</a> register when an Auto CMD12 Error interrupt occurs. This register is valid only when Auto CMD12 is enabled ( <a href="#">MMCHS_CMD[2]</a> ACEN) and Auto CMD12Error ( <a href="#">MMCHS_STAT[24]</a> ACE) is set to 1. Note: These bits are automatically reset when starting a new adtc command with data.	
<b>Type</b>	R	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CNI	RESERVED	ACIE	ACEB	ACCE	ACTO	ACNE									

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Reserved These bits are initialized to zero, and writes to them are ignored.	R	0x000000
7	CNI	Command not issue by Auto CMD12 error If this bit is set to 1, it means that pending command is not executed due to Auto CMD12 error : ACEB, ACCE, ACTO or ACNE.  Read 0x0: Not error Read 0x1: Command not issued	R	0
6:5	RESERVED	Reserved These bits are initialized to zero, and writes to them are ignored.	R	0x0
4	ACIE	Auto CMD12 index error This bit is a set to 1 when response index differs from corresponding command auto CMD12 index previously emitted. This bit depends on the command index check enable ( <a href="#">MMCHS_CMD[20]</a> CICE).  Read 0x0: No error Read 0x1: Auto CMD12 Index Error	R	0
3	ACEB	Auto CMD12 end bit error This bit is set to 1 when detecting a 0 at the end bit position of auto CMD12 command response.  Read 0x0: No error Read 0x1: AutoCMD12 End bit Error	R	0
2	ACCE	Auto CMD12 CRC error This bit is automatically set to 1 when a CRC7 error is detected in the auto CMD12 command response depending on the enable in <a href="#">MMCHS_CMD[19]</a> CCCE register.  Read 0x0: No error Read 0x1: Auto CMD12 CRC Error	R	0
1	ACTO	Auto CMD12 timeout error This bit is set to 1 if no response is received within 64 clock cycles from the end bit of the auto CMD12 command.  Read 0x0: No error Read 0x1: Auto CMD12 Time Out	R	0

Bits	Field Name	Description	Type	Reset
0	ACNE	Auto CMD12 not executed This bit is set to 1 if multiple block data transfer command has started and if an error occurs in command before Auto CMD12 starts. Read 0x0: Auto CMD12 Executed Read 0x1: Auto CMD12 Not Executed	R	0

<b>Description</b>	<p>ADMA Error Status Register</p> <p>When ADMA Error Interrupt is occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. For recovering the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:</p> <p>ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address</p> <p>ST_FDS: Current location set in the ADMA System Address register is the error descriptor address</p> <p>ST_CADR: This state is never set because do not generate ADMA error in this state.</p> <p>ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address</p> <p>In case of write operation, the Host Driver should use ACMD22 to get the number of written block rather than using this information, since unwritten data may exist in the Host Controller. The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.</p>

25.6 General-Purpose Interface Register Manual .....	5117

## 25.1 General-Purpose Interface Overview

The general-purpose interface combines six general-purpose input/output (GPIO) banks.

Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 192 (6 × 32) pins.

These pins can be configured for the following applications:

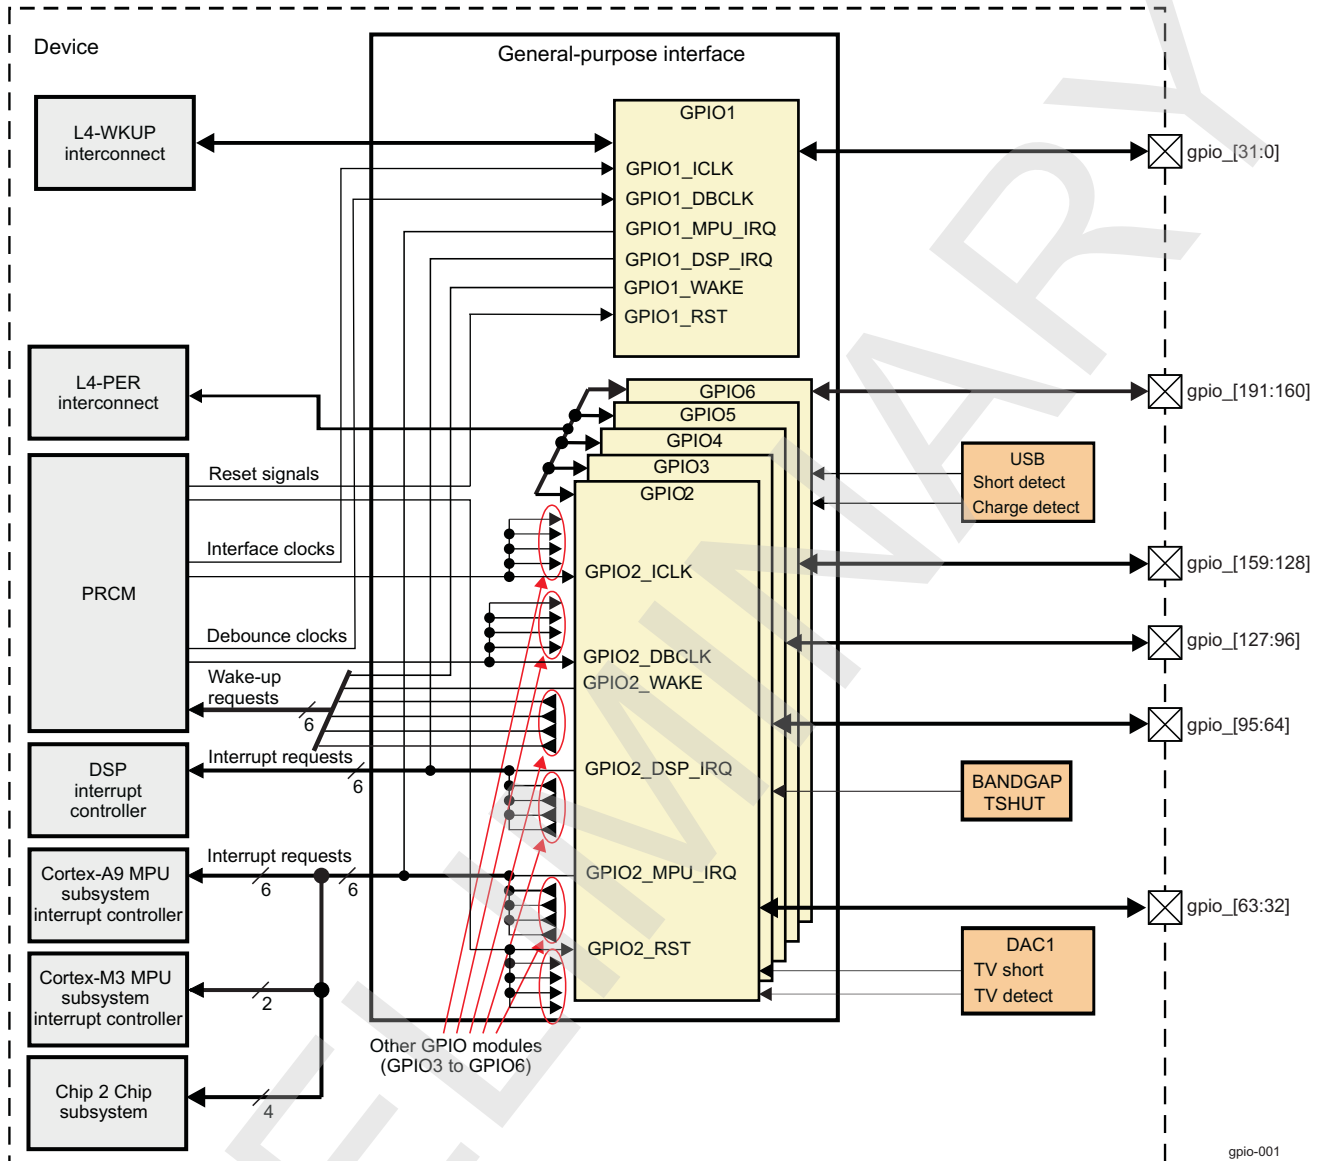

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.
- Wake-up request generation in idle mode upon the detection of external events

These modules do not include pad control (pullup/pulldown control, open-drain feature). For more information, see [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 18, Control Module](#).

[Figure 25-1](#) shows an overview of the general-purpose interface.

Figure 25-1. General-Purpose Interface Overview

The GPIO modules include the following global features:

- Synchronous interrupt requests in active mode from each channel are processed by two identical interrupt generation submodules used independently by the digital signal processor (DSP) and microprocessor unit (MPU) Cortex™-A9 and Cortex™-M3 subsystems. One of these interrupts is mapped on the digital signal processor (DSP) subsystem interrupt controller and the other on the MPU Cortex-A9 and Cortex-M3 subsystem interrupt controllers (INTCs).
- Asynchronous wake-up requests in idle mode from input channels are merged together to issue one wake-up signal per GPIO module.
- Data input (capture)/output (drive)
- Power management support

The general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance).

Each GPIO module produces a wake-up request signal to the power, reset, and clock management (PRCM) module.

Each channel in the GPIO modules has the following features:

- The GPIOi.GPIO\_OE register controls the output capability for each pin.

- The output line level reflects the value written in the GPIOi.GPIO\_DATAOUT register through the L4 interconnect.
- The input line can be fed to the GPIO module through an optional and configurable debounce cell. (Because the debouncing time value is global for all ports of one GPIO module, up to five different debouncing time values are possible.)
- The input line value is sampled into the GPIOi.GPIO\_DATAIN register and can be read through the L4 interconnect.
- In active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level used (logical 0, logical 1, or both) can be configured.
- In idle mode, the input line can be used to activate the asynchronous wake-up request (on edge detection: rising edge, falling edge, or both).

The module provides an alternative to the atomic test and set operations for the following registers:

- GPIOi.GPIO\_DATAOUT
- GPIOi.GPIO\_IRQSTATUS\_SET\_0
- GPIOi.GPIO\_IRQSTATUS\_SET\_1
- GPIOi.GPIO\_IRQSTATUS\_CLR\_0
- GPIOi.GPIO\_IRQSTATUS\_CLR\_1
- GPIOi.GPIO\_IRQWAKEN\_0
- GPIOi.GPIO\_IRQWAKEN\_1

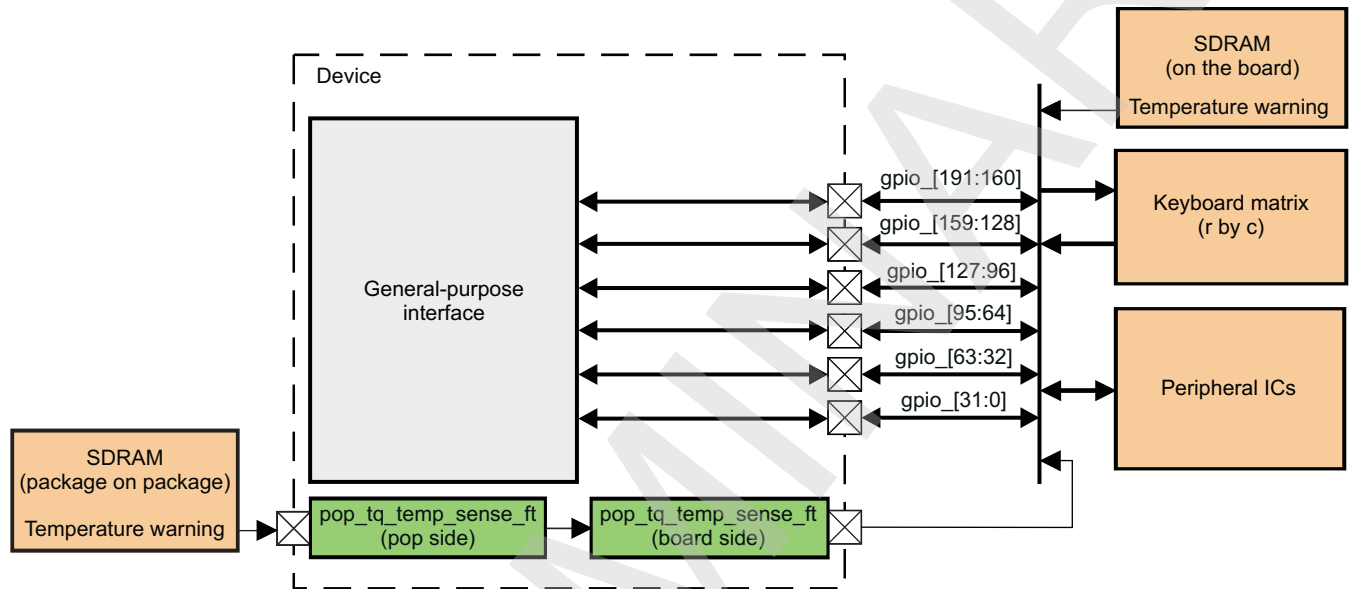

For these registers, the modules implement the set-and-clear protocol register update (see [Section 25.4.9, General-Purpose Interface Set-and-Clear Protocol](#)).

## 25.2 General-Purpose Interface Environment

The general-purpose interface combines six GPIO modules for a flexible, user-programmable, GPIO controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The general-purpose interface allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

Figure 25-2 shows a typical application using the general-purpose interface.

Figure 25-2. General-Purpose Interface Typical Application

gpio-002

**NOTE:** Most memories provide a temperature sensor to control the autorefresh duty cycle. The device monitors the temperature of the external memory using the pop\_tq\_temp\_sense\_ft ball and a GPIO input. To do this, pop\_tq\_temp\_sense\_ft is connected to a GPIO through the customer board. This feature is application-dependent.

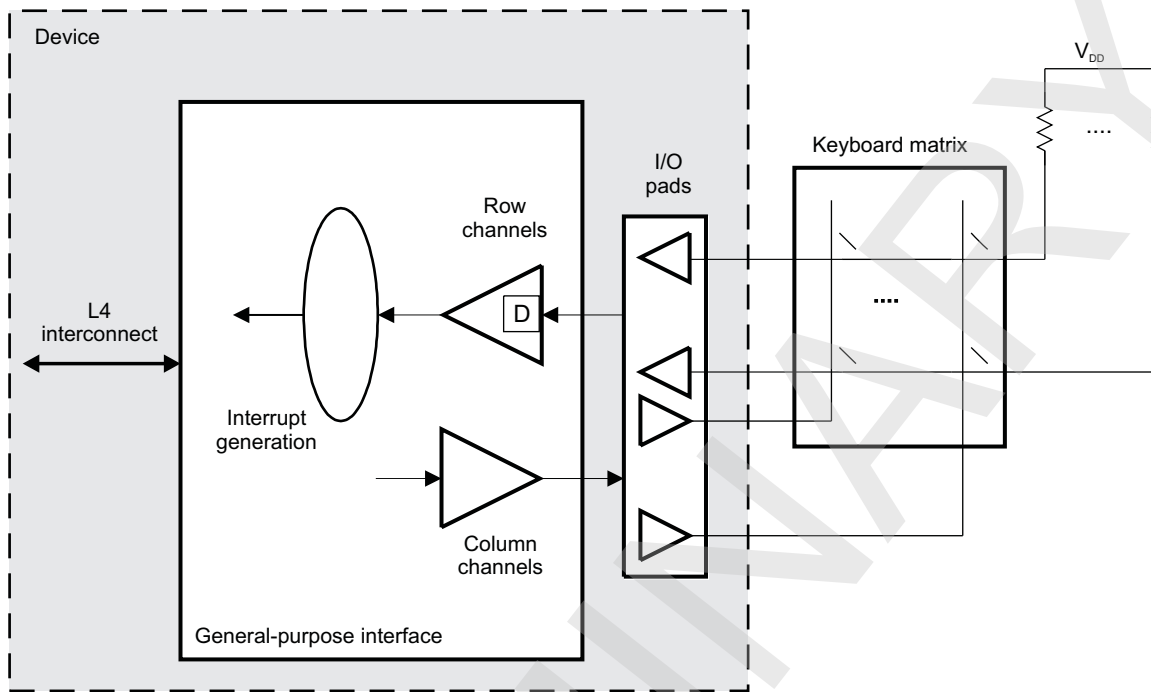

### CAUTION

Because of buffer strength, an external serial resistor must be connected to the balls where gpio\_120 through gpio\_129 are muxed with MMC signals.

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

### 25.2.1 General-Purpose Interface as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface. Channels can be dedicated based on the keyboard matrix (r \* c). Figure 25-3 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pullup. Column channels are configured as outputs and drive a low level.

**Figure 25-3. General-Purpose Interface Used as a Keyboard Interface**

gpio-003

When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see [Section 25.4.6, Interrupt and Wake-up Requests](#)).

When the keyboard interrupt is received, the processor (MPU and/or DSP subsystem) can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

## 25.2.2 General-Purpose Interface Signals

[Table 25-1](#) describes the module signals.

**Table 25-1. I/O**

Signal	I/O <sup>(1)</sup>	Description	Reset Value
gpio_[31:0]	I/O	GPIO	HiZ
gpio_[63:32]	I/O	GPIO	HiZ
gpio_[95:64]	I/O	GPIO	HiZ
gpio_[127:96]	I/O	GPIO	HiZ
gpio_[159:128]	I/O	GPIO	HiZ
gpio_[191:160]	I/O	GPIO	HiZ

<sup>(1)</sup> I = Input; O = Output

Figure 25-4 shows the signal connections of GPIO module 1.

Figure 25-4. GPIO1 Signal Connections

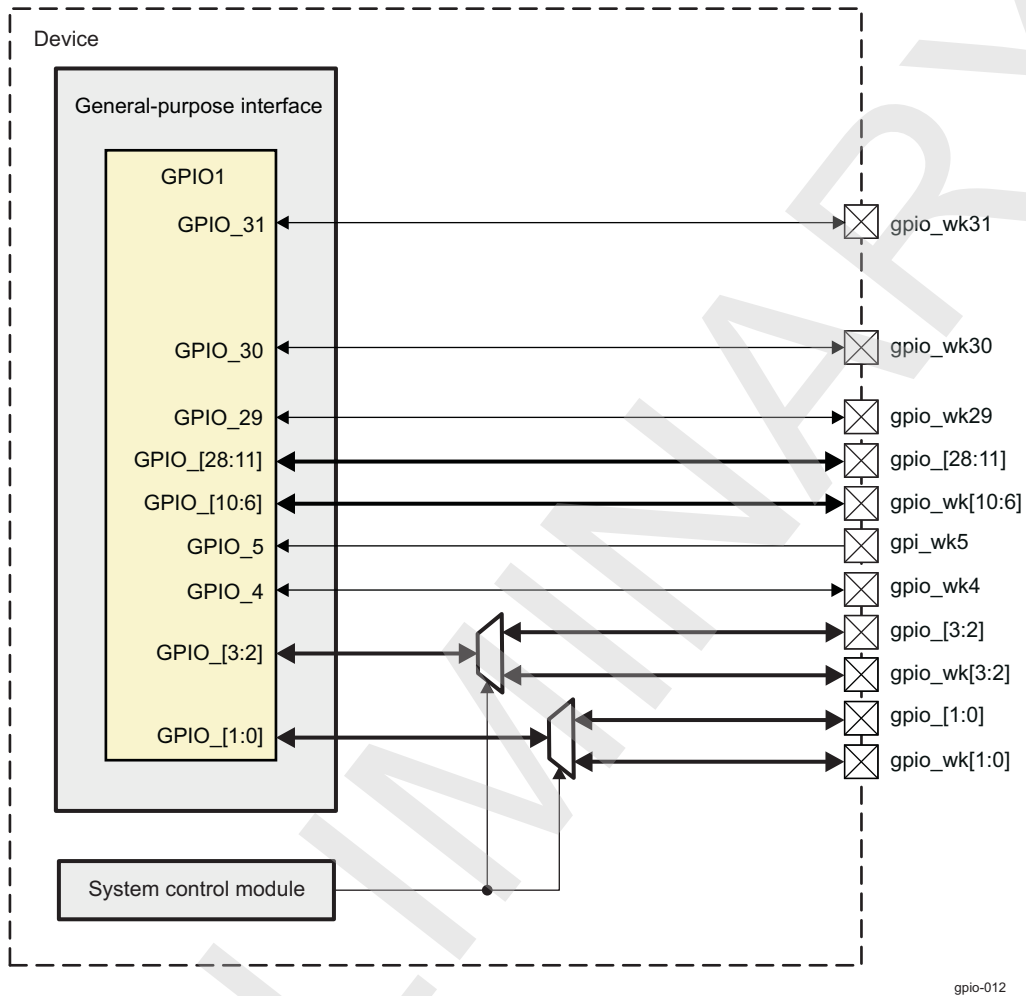

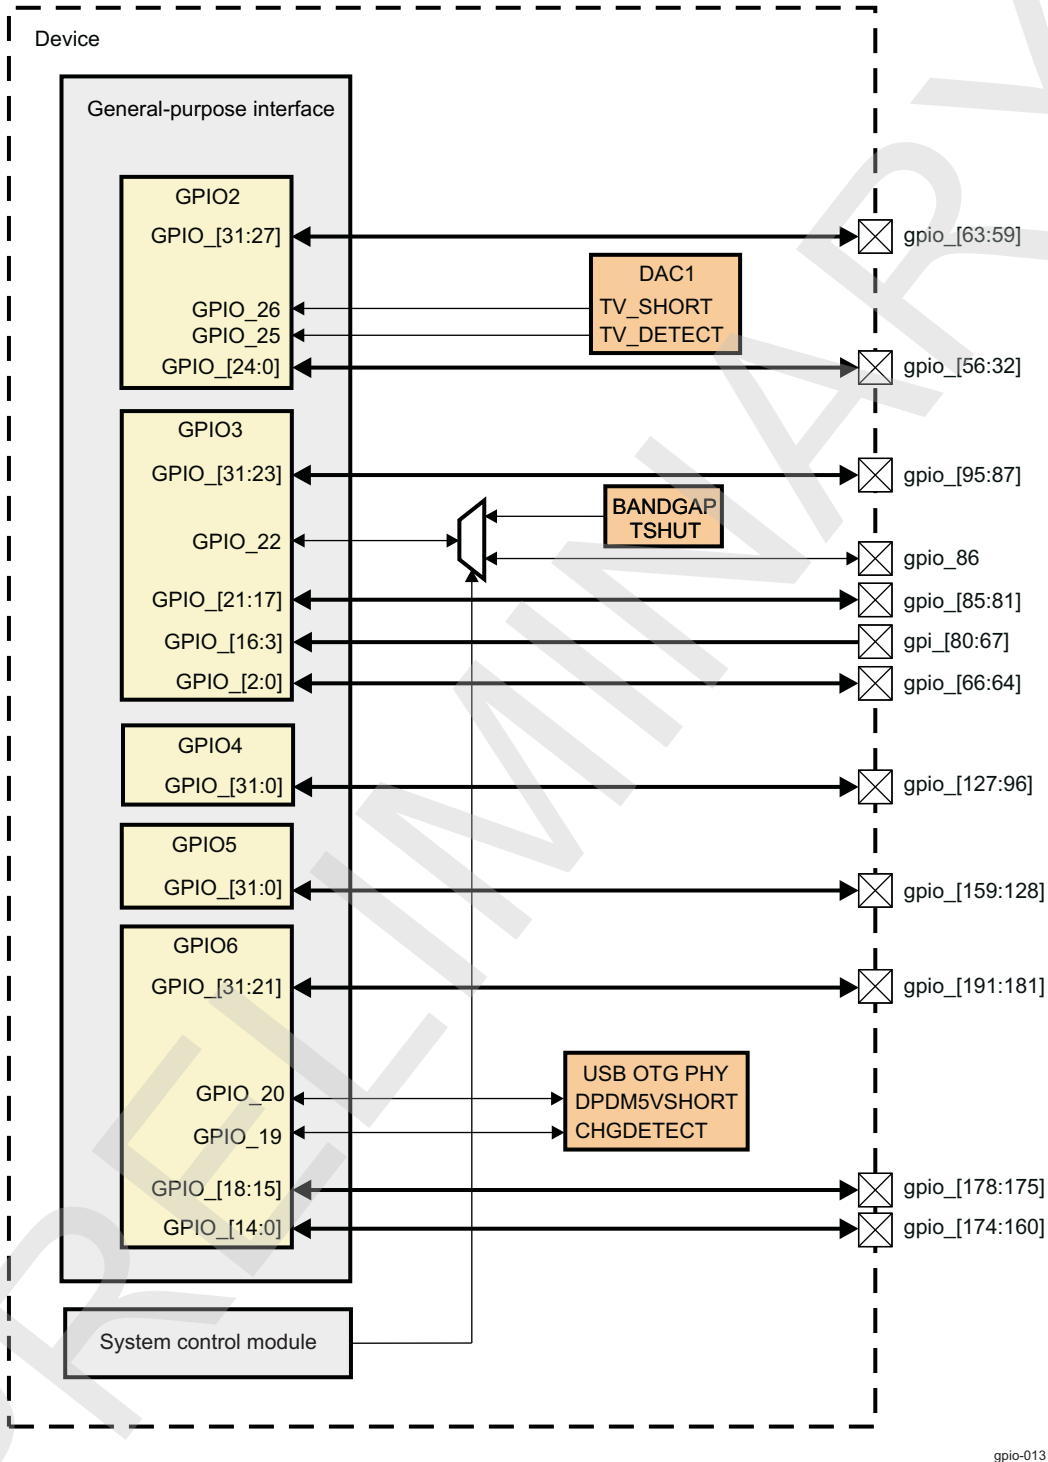

Figure 25-5 shows the signal connections of GPIO modules 2 through 6.

Figure 25-5. GPIO2 through GPIO6 Signal Connections

**NOTE:** For more information about the GPIO1 through GPIO6 signals and channel descriptions, see [Section 25.4.7, General-Purpose Interface Channels Description](#).

**NOTE:** For more information about GPIO signal multiplexing, see [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 18, Control Module](#).

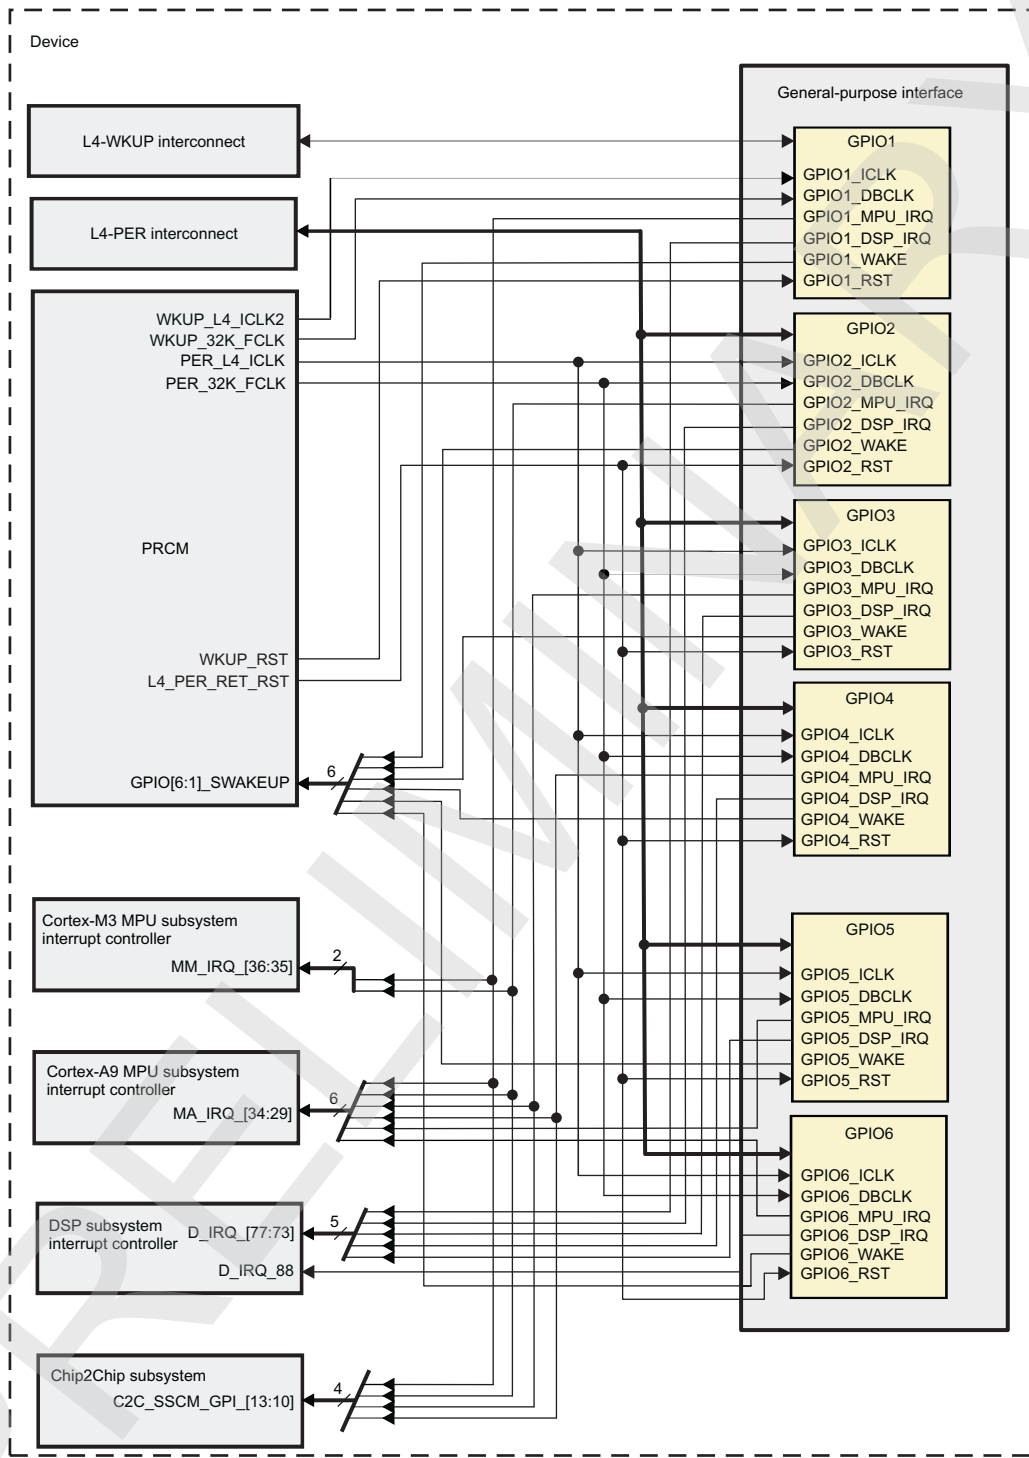

---

### 25.3 General-Purpose Interface Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

[Figure 25-6](#) shows this module integration.

Figure 25-6. GPIO Integration

gpio-004

**NOTE:** For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 25-2 through Table 25-4 summarize the integration of the module in the device.

**Table 25-2. Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect

GPIO4	GPIO4_MPU_IRQ	C2C_SSCM_GPI_13	C2C	An interrupt to distant device through C2C subsystem (first interrupt)
GPIO5	GPIO5_DSP_IRQ	D_IRQ_77	DSP	An interrupt to DSP (second interrupt)
GPIO5	GPIO5_MPU_IRQ	MA_IRQ_33	Cortex-A9	An interrupt to MPU subsystem INTC (first interrupt)
GPIO6	GPIO6_DSP_IRQ	D_IRQ_88	DSP	An interrupt to DSP (second interrupt)
GPIO6	GPIO6_MPU_IRQ	MA_IRQ_34	Cortex-A9	An interrupt to MPU subsystem INTC (first interrupt)

**NOTE:** For a description of interrupt source, see [Section 25.4.6, Interrupt and Wake-Up Requests](#).

## 25.4 General-Purpose Interface Functional Description

### 25.4.1 General-Purpose Interface Block Diagram

Figure 25-7 shows the general-purpose interface.

Figure 25-7. General-Purpose Interface Description

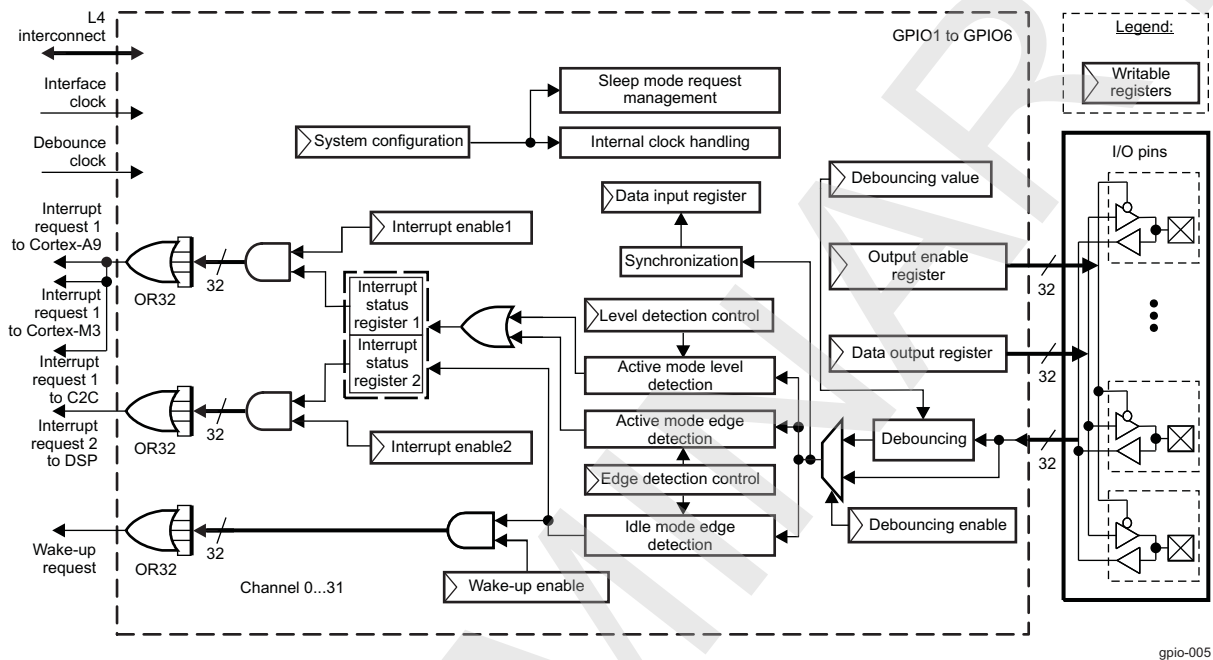

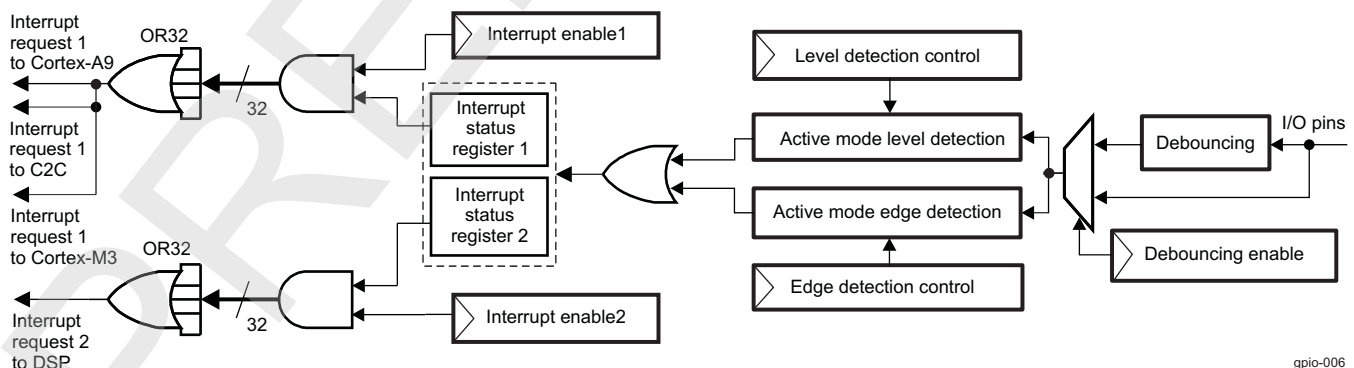

Figure 25-7 shows the details of the GPIO modules in the general-purpose interface block diagram, including their configuration registers and main functional paths:

- The synchronous path (for active mode operation) used to generate a synchronous interrupt request on expected event detection on any input GPIO. Synchronous interrupt request lines 1 and 2 are active based on their respective interrupt enable 1 and 2 registers (GPIOi.GPIO\_IRQSTATUS\_SET\_0, GPIOi.GPIO\_IRQSTATUS\_SET\_1, GPIOi.GPIO\_IRQSTATUS\_CLR\_0, and GPIOi.GPIO\_IRQSTATUS\_CLR\_1). See Figure 25-8.

Figure 25-8. Synchronous Path

- The asynchronous path (for idle mode operation) used to generate an asynchronous wake-up request on the expected edge detection on any input GPIO. The asynchronous wake-up request line is active based on the wake-up-enable register. See Figure 25-9.

Figure 25-9. Asynchronous Path

- The blocks handling the internal clock (clock gating) and managing the sleep mode request/acknowledge protocol (enabling the synchronous path in active mode and the asynchronous path in idle mode)

## 25.4.2 General-Purpose Interface Interrupt and Wake-Up Features

### 25.4.2.1 Synchronous Path: Interrupt Request Generation

The general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance). The 12 interrupt signals are GPIOi\_MPU\_IRQ (used by the MPU and C2C subsystems) and GPIOi\_DSP\_IRQ (used by the DSP subsystem), where  $i = 1, 2, 3, 4, 5, \text{ or } 6$ .

Synchronous interrupt requests from each channel are processed by two identical interrupt generation submodules used independently by the DSP subsystem on one side and by the MPU and C2C subsystems on the other side. Each submodule controls its own synchronous interrupt request line and has its own interrupt enable (GPIOi.GPIO\_IRQSTATUS\_SET\_0, GPIOi.GPIO\_IRQSTATUS\_SET\_1, GPIOi.GPIO\_IRQSTATUS\_CLR\_0, or GPIOi.GPIO\_IRQSTATUS\_CLR\_1), and interrupt status (GPIOi.GPIO\_IRQSTATUS\_0 or GPIOi.GPIO\_IRQSTATUS\_1) registers. The interrupt-enable register selects the channel(s) considered for the interrupt request generation, and the interrupt status register determines which channel(s) activate the interrupt request. Event detection on GPIO channels is reflected in the interrupt status registers independent of the content of the interrupt-enable registers.

In active mode, when the GPIO configuration registers are set to enable the interrupt generation (see Section 25.4.6, *Interrupt and Wake-up Requests*), a synchronous path samples the transitions and levels on the input GPIO with the internally gated interface clock (see Section 25.4.5.2.4, *Module Power Saving*). When an event matches the programmed settings (see Section 25.4.6, *Interrupt and Wake-up Requests*), the corresponding bit in the interrupt status register is set to 1 and, on the following interface clock cycle, interrupt lines 1 and/or 2 are activated (depending on the interrupt-enable registers).

Because of the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (the internally gated interface clock period equals  $N$  times the interface clock period (see Section 25.4.5.2.4, *Module Power Saving*)). This minimum pulse width must be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

Because the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This latency must not exceed four internally gated interface clock cycles + one interface clock cycle when the debounce feature is not used.

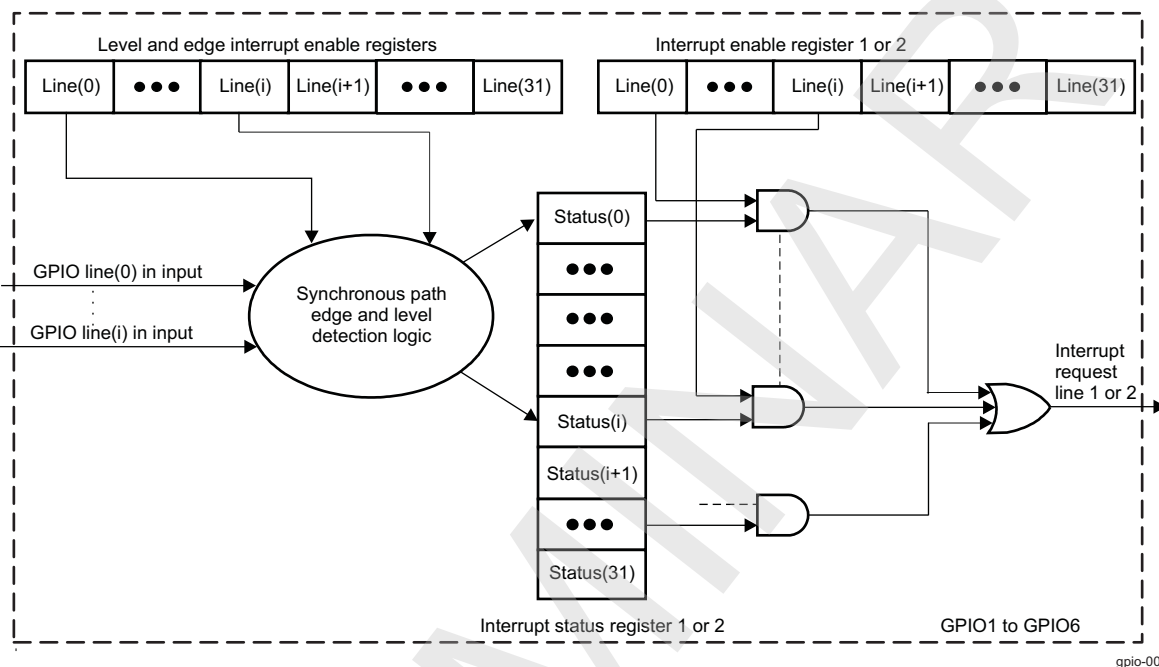

When the debounce feature is active, the latency depends on the value of the debouncing time register (GPIOi.GPIO\_DEBOUNCINGTIME) (see Section 25.4.3, *General-Purpose Interface Clock Configuration*) and is less than three internally gated interface clock cycles + two interface clock cycles + GPIOi.GPIO\_DEBOUNCINGTIME register value debounce clock cycles + three debounce clock cycles.

Synchronous interrupt request line 1 is mapped on the Cortex-A9 MPU, Cortex-M3 MPU and C2C subsystem.

Synchronous interrupt request line 2 is mapped on the DSP INTC.

Figure 25-10 is an overview of the interrupt request generation.

Figure 25-10. Interrupt Request Generation

### 25.4.2.2 Asynchronous Path: Wake-Up Request Generation

The general-purpose interface has six wake-up lines (one wake-up line per GPIO module instance) connected to the PRCM module.

Asynchronous wake-up requests from input channels are merged to issue one wake-up signal to the system per GPIO module. The wake-up-enable registers (GPIOi.GPIO\_IRQWAKEN\_0 and GPIOi.GPIO\_IRQWAKEN\_1) select the channel(s) considered for the wake-up request generation. The asynchronous wake-up request is reflected into the synchronous interrupt status registers (GPIOi.GPIO\_IRQSTATUS\_0 and GPIOi.GPIO\_IRQSTATUS\_1).

In idle mode (the interface clock is shut down and the GPIO configuration registers are programmed; see Section 25.4.6, *Interrupt and Wake-Up Requests*), an asynchronous path detects the expected transition(s) on a GPIO input (based on register programming) and activates an asynchronous wake-up request by the sideband signal (GPIOi\_SWAKEUP, where i = 1, 2, 3, 4, 5, or 6), if the wake-up-enable register is set.

When the system is awakened, the interface clock is restarted and synchronously set to 1 based on the input GPIO pin triggering the wake-up request and the corresponding bit in the interrupt status registers (GPIOi.GPIO\_IRQSTATUS\_0 and GPIOi.GPIO\_IRQSTATUS\_1). On the following internal clock cycle, interrupt lines 1 and/or 2 are active (active low) when the corresponding bits are set in the interrupt-enable registers (GPIOi.GPIO\_IRQSTATUS\_SET\_0, GPIOi.GPIO\_IRQSTATUS\_SET\_1, GPIOi.GPIO\_IRQSTATUS\_CLR\_0 and GPIOi.GPIO\_IRQSTATUS\_CLR\_1).

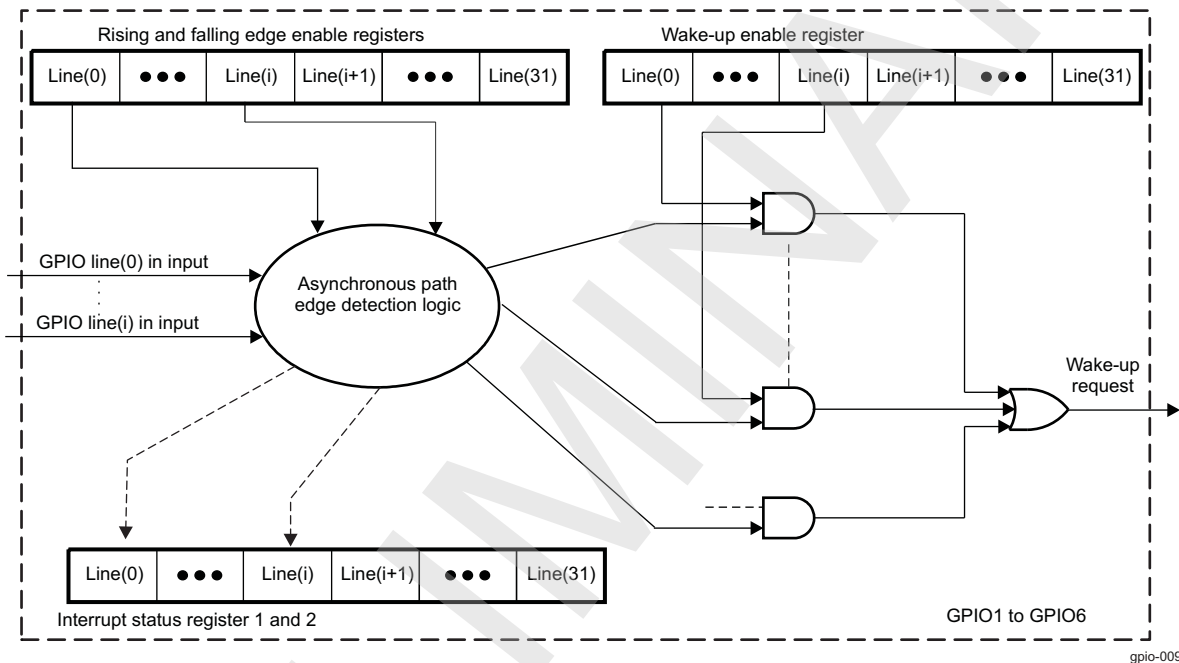

**NOTE:** When debouncing is not enabled, a minimum input pulse width does not trigger the wake-up request because there is no sampling operation.

When debouncing is enabled, the minimum pulse width is set by the specified debouncing time.

The GPIOi.GPIO\_SYSCONFIG[2] ENAWAKEUP bit enables or disables the GPIO wake-up feature globally. If the bit is 0, the wake-up-enable registers (GPIOi.GPIO\_IRQWAKEN\_0 and GPIOi.GPIO\_IRQWAKEN\_1) have no effect.

Figure 25-11 is an overview of the wake-up request generation.

**Figure 25-11. Wake-Up Request Generation**

### 25.4.2.3 Wake-Up Event Conditions During Transition To and From IDLE State

Figure 25-12 shows the wake-up event conditions.

In phase A, only the synchronous path is enabled. A synchronous interrupt request (see [Section 25.4.2.1, Synchronous Path: Interrupt Request Generation](#)) activates the interrupt line(s) and prevents the GPIO from transitioning into IDLE state until the interrupt is cleared.

In phase B, the asynchronous path and synchronous path are enabled during the first five functional clock cycles of the SLEEPTRANS state. During this period a synchronous interrupt request (see [Section 25.4.2.1, Synchronous Path: Interrupt Request Generation](#)) prevents the GPIO from transitioning into IDLE state. A shorter pulse puts the module into IDLE state but triggers a wakeup once in IDLE.

In phase C, only the asynchronous path is enabled. A wake-up request (see [Section 25.4.2.2, Asynchronous Path: Wake-Up Request Generation](#)) triggers a wake-up request from the GPIO and when the module is awakened an interrupt is generated. If debouncing is not enabled, there is no minimum input pulse width to trigger the wake-up request.

In phase D, eight OCP clock cycles occur until the module is in FUNCT state, the synchronous path is enabled, and an event that fulfills the pulse width requirements (see [Section 25.4.2.1, Synchronous Path: Interrupt Request Generation](#)) activates the interrupt line(s).

In phase E, only the synchronous path is enabled. A synchronous interrupt request (see [Section 25.4.2.1, Synchronous Path: Interrupt Request Generation](#)) activates the interrupt line(s).

Figure 25-12. Wake-Up Event Conditions

gpio-014

#### 25.4.2.4 Interrupt (or Wake-Up) Line Release

When the host processor (the MPU and/or DSP subsystem in the device) receives an interrupt request issued by the GPIO module, it reads the corresponding interrupt status register (GPIOi.GPIO\_IRQSTATUS\_0 or GPIOi.GPIO\_IRQSTATUS\_1) to determine which GPIO input triggered the interrupt (or the wake-up request).

After servicing the interrupt (or acknowledging the wake-up request), the processor resets the status bit and releases the interrupt line by writing 1 in the corresponding bit of the interrupt status register. If there is still a pending interrupt request to serve (all bits in the interrupt status register that are not masked by the interrupt-enable register are not cleared), the interrupt line is reasserted.

---

**NOTE:** The status bit must be reset to re-enter idle mode.

---

### 25.4.3 General-Purpose Interface Clock Configuration

#### 25.4.3.1 Clocking

Each GPIO module uses two clocks:

- **Debounce clock:** The 32-kHz debounce clock, GPIOi\_DBCLK, (where i = 1, 2, 3, 4, 5, or 6, with one debounce clock per module), comes from the PRCM module and is used for the debounce cell logic (without the corresponding configuration registers). This cell can sample the input line and filters the input level using a programmed delay.

The debouncing value register (GPIOi.GPIO\_DEBOUNCINGTIME) is used to set the debouncing time for all input lines in the GPIO module. The value is global for all the ports of one GPIO module, so up to six different debouncing values are possible. The debounce cell is running with the debounce clock (32 kHz). This register represents the number of clock cycle(s) to be used (one cycle is 31 μs long).

The following formula describes the required input stable time to be propagated to the debounced output:

Required input line stable = (GPIOi.GPIO\_DEBOUNCINGTIME[7:0] DEBOUNCVL bit field value + 1) × 31,

where the value of the GPIOi.GPIO\_DEBOUNCINGTIME[7:0] DEBOUNCVL bit field is from 0 to 255.

For more information, see [Section 3.6.8, CD\\_L4\\_PER\\_Clock Domain](#), and [Section 3.6.4, CD\\_WKUP\\_Clock Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

- **Interface clock:** The interface clock, GPIOi\_ICLK (where i = 1, 2, 3, 4, 5, or 6), comes from the PRCM module and is used throughout the GPIO module (except within the debounce cell logic). GPIOi\_ICLK clocks the data exchanges between the L4 interconnect and the internal logic. The clock-gating features allow module power consumption to be adapted to the activity.

For more information, see [Section 3.6.8, CD\\_L4\\_PER\\_Clock Domain](#), and [Section 3.6.4, CD\\_WKUP\\_Clock Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 25-3](#) describes the GPIO module clocks.

[Table 25-5](#) summarizes the functional clock configuration.

**Table 25-5. Functional Clock Configuration**

Interface Clock	GPIO_CTRL[2:1] GATINGRATIO	Functional Clock
GPIOi_ICLK where i = 1 to 6	00	GPIOi_ICLK /1, where i = 1 to 6
GPIOi_ICLK where i = 1 to 6	01	GPIOi_ICLK /2, where i = 1 to 6
GPIOi_ICLK where i = 1 to 6	10	GPIOi_ICLK /4, where i = 1 to 6
GPIOi_ICLK where i = 1 to 6	11	GPIOi_ICLK /8, where i = 1 to 6

### 25.4.4 General-Purpose Interface Hardware and Software Reset

The GPIO can be reset by using the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in each GPIO module.

- **Hardware reset:** The GPIO2 to GPIO6 modules are attached to the PER\_RST reset domain. The GPIO1 module is attached to the WKUP\_RST reset domain.

The hardware reset has a global reset action on the GPIO modules of the general-purpose interface. All configuration registers and internal logic are reset when it is active (low level). In each GPIO module, the GPIOi.GPIO\_SYSTATUS[0] RESETDONE bit monitors the internal reset status; it is set when the reset completes. For more information, see [Section 3.5.4, Reset Domains](#), in [Chapter 3, Power, Reset, and Clock Management](#).

- **Software reset:** Each GPIO module has its own software reset using the GPIOi.GPIO\_SYSCONFIG[1] SOFTRESET bit (where i = 1, 2, 3, 4, 5, or 6). The software reset has the same effect as the hardware reset signal, but this reset can be applied on one or more modules.

Writing 1 to the GPIOi.GPIO\_SYSCONFIG[1] SOFTRESET bit, (where i = 1, 2, 3, 4, 5, or 6) resets the module. A bit value of 1 remains until the reset is complete. When the software reset is complete, the GPIOi.GPIO\_SYSCONFIG[1] SOFTRESET bit is automatically reset to 0 and has the same effect as a hardware reset. The GPIOi.GPIO\_SYSTATUS[0] RESETDONE bit is cleared during a software reset.

This bit is set to 1 when the software reset is complete.

## **25.4.5 General-Purpose Interface Power Management**

### **25.4.5.1 Power Domain**

The GPIO1 module is attached to the WKUP power domain (see [Section 3.1.1.2, Power Management, in Chapter 3, Power, Reset, and Clock Management](#)). This domain is composed of the logic permanently supplied to manage domain power state transitions and detect wake-up events. The WKUP power domain is continuously active. Modules GPIO2 to GPIO6 are attached to the PER power domain (see [Section 3.1.1.2, Power Management, in Chapter 3, Power, Reset, and Clock Management](#)). The PER power domain is not active continuously.

### **25.4.5.2 Power Management**

#### **25.4.5.2.1 Idle Scheme**

To reduce dynamic consumption, an efficient idle scheme is based on the following:

- An efficient local autclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without requiring complex software management.

The idle mode request, idle acknowledge, and wake-up request (GPIOi\_WAKEUP, where i = 1, 2, 3, 4, 5, or 6) are sideband signals between the PRCM module and the general-purpose interface (see [Section 25.4.6.2, Wake-Up Request Generation](#)).

#### **25.4.5.2.2 Operating Modes**

The following four operating modes are defined for the modules:

- **Active mode:** The module runs synchronously on the interface clock; interrupts can be generated based on the configuration and external signals.
- **Idle mode:** Power-saving mode with the module in a waiting state. The interface clock can be stopped, an interrupt cannot be generated, and a wake-up signal can be generated based on the configuration and external signals.  
If the debounce clock provided by the PRCM module is active, the debounce cell can sample and filter the input to generate a wake-up event. If the debounce clock is inactive, the debounce cell gates all input signals and thus cannot be used.
- **Inactive mode:** The module has no activity. The interface clock can be stopped, an interrupt cannot be generated, and the wake-up feature is inhibited.
- **Disabled mode:** The module is not used. The internal clock paths are gated, and an interrupt or wake-up request cannot be generated.

The idle and inactive modes are configured within the module and activated on request by the PRCM module (see [Section 3.1.1.2, Power Management in Chapter 3, Power, Reset, and Clock Management](#)) through sideband signals (see [Section 25.4.5.2.3, System Power Management and Wakeup](#)).

The disabled mode is set by software through a dedicated configuration bit, the GPIOi.GPIO\_CTRL[0] DISABLEMODULE bit (0: The module is enabled and clocks are not gated; 1: The module is disabled and clocks are gated). It unconditionally gates the internal clock paths that are not used for the L4 interconnect.

#### **25.4.5.2.3 System Power Management and Wakeup**

The PRCM module can require the GPIO modules to be idled for power-saving purposes.

The general-purpose interface has six identical idle mode request/acknowledge (handshake) mechanisms with the PRCM module (see [Section 25.4.6.2, Wake-Up Request Generation](#)): one per GPIO module. The general-purpose interface allows the GPIO modules to enter idle mode based on the GPIOi.GPIO\_SYSCONFIG[4:3] IDLEMODE bit field.

Idle acknowledge depends on the configuration and activity of each GPIO module:

- Smart-idle mode

When the GPIO module is configured in smart-idle mode, it checks for more activity (capture of the input GPIO pins in the GPIOi.GPIO\_DATAIN register is complete with no pending interrupt; all interrupt status bits are cleared), and there is no access to the GPIO.GPIO\_DEBOUNCINGTIME register, which is waiting to be synchronized.

Idle acknowledge is then asserted and the module enters into idle-mode. It waits for active system clock gating by the PRCM module (when all peripherals supplied by the same L4 interface clock domain are also ready for idle).

In idle mode (that is, when the PRCM module gates the interface clock), no interrupt occurs and the module is ready to issue a wake-up request.

When the expected transition occurs on an enabled GPIO input pin, the GPIO module exits from idle mode if the GPIOi.GPIO\_SYSCONFIG[2] ENAWAKEUP bit is set to 1 (wake-up capability enabled).

- Smart-idle wake-up mode

If the GPIOi.GPIO\_SYSCONFIG[4:3] IDLEMODE bit field selects smart-idle or smart-idle wake-up mode, the GPIO module evaluates its internal capability to switch off the interface clock. Once all internal activity ceases (the DATA INPUT REGISTER completed to capture the input GPIO pins, there is no pending interrupt, all interrupt status bits are cleared, and there is no write access to the GPIO\_DEBOUNCINGTIME register pending to be synchronized), the Idle acknowledge is asserted and the GPIO enters into idle mode, ready to issue a wake-up request when the expected transition occurs on an enabled GPIO input pin. This wake-up request is effectively sent only if the GPIOi.GPIO\_SYSCONFIG[2] ENAWAKEUP bit of the system configuration register enables the GPIO wake-up capability (see [Section 25.6.2.2, System Configuration Register](#)). When the system is awake, the idle request goes inactive, the idle acknowledge and wake-up request (if the GPIO triggered the systems wakeup) signals are immediately deasserted, and the asynchronous wake-up request (if existing) is reflected into the synchronous interrupt status registers.

- Force-idle mode

When the GPIO module is configured in force-idle mode (the GPIOi.GPIO\_SYSCONFIG[4:3] IDLEMODE bit field = 2b00) and receives an idle request from the PRCM module, the GPIO module waits unconditionally for active system clock gating by the PRCM module. (This occurs only when all peripherals supplied by the same L4 interface clock domain are also ready for idle.)

When in idle mode (that is, when the PRCM module gates the interface clock), the module (in inactive mode) has no activity, the interface clock paths are gated, an interrupt cannot be generated, and the wake-up feature is totally inhibited.

- No-idle mode

When the GPIO module is configured in no-idle mode (the GPIOi.GPIO\_SYSCONFIG[4:3] IDLEMODE bit field = 2b01) and receives an idle request from the PRCM module, the GPIO module does not go into idle mode and the idle acknowledge is never sent.

---

**NOTE:** For more information about idle modes, see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

---

#### 25.4.5.2.4 Module Power Saving

The GPIO module has local power management by internal clock-gating features:

- Internal interface clock gating: The clock for the L4 interconnect logic can be gated when the module is not accessed, if the GPIOi.GPIO\_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock.
- Clock gating for the input data sample logic: Clock for the input data sample logic can be gated when the data in the GPIOi.GPIO\_DATAIN register is not accessed.
- Clock gating for the event detection logic: Each GPIO module implements four clock groups used for

the logic in the synchronous event detection. Each group of eight input GPIO pins has a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no detection, the corresponding clock is gated.

Grouping the edge/level enable can save the power consumption of the module.

If any of the following registers is set to 0x01 01 01 01, then all clocks are active (power consumption is high). If they are set to 0x00 00 00 FF, then a single clock is active (power saving).

- GPIOi.GPIO\_LEVELDETECT0
- GPIOi.GPIO\_LEVELDETECT1
- GPIOi.GPIO\_RISINGDETECT
- GPIOi.GPIO\_FALLINGDETECT

**NOTE:** When the clocks are enabled by writing to the following registers, the detection starts after five clock cycles. This period is required to clean the synchronization edge/level detection pipeline.

- GPIOi.GPIO\_LEVELDETECT0
- GPIOi.GPIO\_LEVELDETECT1
- GPIOi.GPIO\_RISINGDETECT
- GPIOi.GPIO\_FALLINGDETECT

The mechanism is independent of each clock group. If the clock has been started before and a new setting is performed, the following is recommended:

1. Set the new detection required.
2. Disable the previous setting (if necessary).

In this way, the corresponding clock is not gated and the detection starts immediately.

All channels are also gated using a one-out-of-N scheme. N is the GPIOi.GPIO\_CTRL[2:1] GATINGRATIO bit field and can take the values 1 (2b00), 2 (2b01), 4 (2b10), or 8 (2b11). The interface clock is enabled for this logic one cycle every N cycles. When N is equal to 1, there is no gating and this logic is free-running on the interface clock. When N is 2, 4, or 8, this logic is running at the equivalent frequency of interface clock frequency divided by N.

- Inactive mode: In inactive mode, all internal clock paths are gated.
- Disabled mode: All internal clock paths not used for the L4 interconnect are gated. The GPIOi.GPIO\_CTRL[0] DISABLEMODULE bit controls a clock-gating feature at the module level. When set to 1, this bit forces clock gating for all internal clock paths. Internal activity in the module is suspended. The L4 interconnect is not affected by this bit.

The interface clock gating is controlled with the GPIOi.GPIO\_SYSCONFIG[0] AUTOIDLE bit, which is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

Table 25-6 describes the power-management features available for the general-purpose interface module.

**NOTE:** For information about source clock gating and a description of sleep/wake-up transitions, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

For descriptions of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

**Table 25-6. Local Power-Management Features**

Feature	Registers	Description
Clock autogating	GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit	Sets the clock gating strategy for the OCP interface block

**Table 25-6. Local Power-Management Features (continued)**

Feature	Registers	Description
Slave idle modes	GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field	Force-idle, no-idle, and smart-idle wake-up-capable modes are available.
Clock activity	GPIOi.GPIO_CTRL[0] DISABLEMODULE bit field	Enable and disable the module.
Debouncing enable	GPIOi.GPIO_DEBOUNCENABLE[31:0] DEBOUNCEENABLE bit field	Debouncing mode is available.
Global wake-up enable	GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit	This bit enables the wake-up feature at module level.
Wake-up sources enable	GPIOi.GPIO_IRQWAKEN_0[31:0] INTLINE register GPIOi.GPIO_IRQWAKEN_1[31:0] INTLINE register	This register enables or disables a specific IRQ request source to generate a wake-up signal.

Table 25-7 describes the clock activity settings.

**Table 25-7. Clock Activity Settings**

GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE	Selected Mode	Description	Wake-Up Events
00	Force-idle	The GPIO module goes into inactive mode independently of the internal module state, and the Idle acknowledge is never sent.	No
01	No-idle	The GPIO module does not go into the idle mode and the idle acknowledge is never sent.	No
10	Smart-idle	The GPIO module evaluates its internal capability to switch off the interface clock. If there is no more internal activity, the idle acknowledge is asserted and the GPIO enters into idle mode.	No
11	Smart-idle wake-up	The GPIO module evaluates its internal capability to have the interface clock switched off. If there is no more internal activity, the idle acknowledge is asserted and the GPIO enters into idle mode.	Yes

## 25.4.6 General-Purpose Interface Interrupt and Wake-Up Requests

### 25.4.6.1 Interrupt Request Generation

All interrupt sources (the 32 GPIO input channels) are merged to issue two synchronous interrupt requests in each GPIO module. Thus, the general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance).

- Synchronous interrupt request line 1 is mapped on the Cortex-A9 and Cortex-M3 MPU INTCs, and on the Chip2Chip subsystem.
- Synchronous interrupt request line 2 is mapped on the DSP INTC.

Table 25-8 lists the event flags, and their mask, that can cause module interrupts.

**Table 25-8. Events**

Event Flag	Event Mask	Synchronous	Sensitivity	Map to	Description
GPIOi.GPIO_IRQSTATUS1[31:0] INTLINE	GPIOi.GPIO_IRQENABLE1[31:0] IRQENABLE1	Yes	Edge/level	MA_IRQ_n MM_IRQ_n <sup>(1)</sup> C2C_SSCM_GPI_n <sup>(2)</sup>	Corresponds to the first line of interrupt
GPIOi.GPIO_IRQSTATUS2[31:0] INTLINE	GPIOi.GPIO_IRQENABLE2[31:0] IRQENABLE2	Yes	Edge/level	D_IRQ_n	Corresponds to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0[31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_S_SET_0[31:0] INTLINE	Yes	Edge/level	MA_IRQ_n MM_IRQ_n <sup>(1)</sup> C2C_SSCM_GPI_n <sup>(2)</sup>	Corresponds to the first line of interrupt

<sup>(1)</sup> For GPIO1 and GPIO2 only

<sup>(2)</sup> For GPIO1 to GPIO4 only

**Table 25-8. Events (continued)**

Event Flag	Event Mask	Synchronous	Sensitivity	Map to	Description
GPIOi.GPIO_IRQSTATUS_1[31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_SET_1[31:0] INTLINE	Yes	Edge/level	D_IRQ_n	Corresponds to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_CLR_0[31:0] INTLINE	Yes	Edge/level	MA_IRQ_n MM_IRQ_n <sup>(1)</sup> C2C_SSCM_GPI_n <sup>(2)</sup>	Corresponds to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1[31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_CLR_1[31:0] INTLINE	Yes	Edge/level	D_IRQ_n	Corresponds to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0[31:0] INTLINE	GPIOi.GPIO_IRQWAKEN_0[31:0] INTLINE	No	Edge/level	MA_IRQ_n MM_IRQ_n <sup>(1)</sup> C2C_SSCM_GPI_n <sup>(2)</sup>	Corresponds to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1[31:0] INTLINE	GPIOi.GPIO_IRQWAKEN_1[31:0] INTLINE	No	Edge/level	D_IRQ_n	Corresponds to the second line of interrupt

Synchronous interrupt request lines 1 and 2 are active depending on their respective interrupt enable 1 and 2 registers (GPIOi.GPIO\_IRQSTATUS\_SET\_0, GPIOi.GPIO\_IRQSTATUS\_SET\_1, GPIOi.GPIO\_IRQSTATUS\_CLR\_0 and GPIOi.GPIO\_IRQSTATUS\_CLR\_1).

- Interrupt enable registers (GPIOi.GPIO\_IRQSTATUS\_SET\_0 and GPIOi.GPIO\_IRQSTATUS\_SET\_1)  
The interrupt enable1 (or interrupt enable2) register allows masking of the expected transition on input GPIO to prevent the generation of an interrupt request on line1 (or line2). The interrupt-enable registers are programmed synchronously with the interface clock.  
These registers can be accessed with direct read/write operations or using the alternate set and clear protocol feature for register update. This feature allows to set or clear explicit bits of these registers with a single write access (see Section 25.4.9, *General-Purpose Interface Set-and-Clear Protocol*).
- Interrupt status registers (GPIOi.GPIO\_IRQSTATUS\_0 and GPIOi.GPIO\_IRQSTATUS\_1)  
The interrupt status1 (or interrupt status2) register determines which of the input GPIO pins triggered the interrupt line1 (or interrupt line2) request (or the wake-up line).  
When a bit in this register is set to 1, it indicates that the corresponding GPIO pin is requesting the interrupt (or the wake-up). To reset a bit in this register, write 1 to the appropriate bit. However, an interrupt cannot be generated by writing 1 to the interrupt status1 (or interrupt status2) register.  
If 0 is written to a bit in this register, the value remains unchanged. The interrupt status1 (or interrupt status2) register is synchronous with the interface clock. In idle mode, the event is detected through an asynchronous path, and the corresponding bit in the interrupt status1 and interrupt status2 registers are set when the GPIO module is awoken.

**CAUTION**

After servicing the interrupt, the status bit in the interrupt status register (GPIOi.GPIO\_IRQSTATUS\_0 or GPIOi.GPIO\_IRQSTATUS\_1) must be reset and the interrupt line released (by writing 1 in the corresponding bit of the interrupt status register) before enabling an interrupt for the GPIO channel in the interrupt-enable register (GPIOi.GPIO\_IRQSTATUS\_SET\_0 or GPIOi.GPIO\_IRQSTATUS\_SET\_1) to prevent the occurrence of unexpected interrupts when enabling an interrupt for the GPIO channel.

**25.4.6.2 Wake-Up Request Generation**

The GPIO1 module of the general-purpose interface is attached to the WKUP power domain (see Section 3.1.1.2, *Power Management*, in Chapter 3, *Power, Reset, and Clock Management*, and can wake up the system.

**NOTE:** The GPIO2 to GPIO6 modules belong to the PER power domain and thus their wake-up capabilities are operational only when the PER power domain is active.

All wake-up sources (the 32 input GPIO channels) are merged together to issue a single asynchronous wake-up request in each GPIO module following the expected transition(s) (based on register programming). Each GPIO module generates a wake-up signal to the PRCM module.

**NOTE:** Only gpio\_wk[10:0] and gpio\_wk[31:29] can be used to generate a direct wake-up event.

The asynchronous wake-up request line is active based on the GPIOi.GPIO\_IRQWAKEN\_0 and GPIO\_IRQWAKEN\_1 wake-up-enable registers (where i = 1, 2, 3, 4, 5, or 6).

The wake-up-enable register allows masking of the expected transition on input GPIO to prevent the generation of a wake-up request. The wake-up-enable register is programmed synchronously with the interface clock before any idle mode request coming from the host processor.

This register can be accessed with direct read/write operations or by using the alternate set and clear protocol register update feature. This feature allows setting or clearing specific bits of this register with a single write access to the set wake-up-enable register (or to the clear wake-up-enable register) address (see Section 25.4.9, *General-Purpose Interface Set-and-Clear Protocol*).

**NOTE:** There must be a correlation between the wake-up enable and interrupt-enable registers. If a GPIO pin has a wake-up configured on it, it must also have the corresponding interrupt enabled (on one of the two interrupt lines). Otherwise, it is possible to have a wake-up event, but after exiting the IDLE state, no interrupt is generated; thus, the corresponding bit from the interrupt status register is not cleared, and the module does not acknowledge a future idle request.

Table 25-9 lists the mapping of the wake-up signals.

**Table 25-9. Wake-Up Signals**

Name	Mapping	Comments
GPIOi_WAKE	GPIOi_SWAKEUP	Where i = 1, 2, 3, 4, 5, and 6. Destination is the PRCM module.

### 25.4.7 General-Purpose Interface Channel Description

Table 25-10 describes the GPIO channels.

**Table 25-10. GPIO Channel Description**

Channel Number	Type <sup>(1)</sup>	Mapping	Wake-Up Feature	Comments
<b>GPIO1 Module</b>				
[31]	I/O	gpio_wk31	Yes	Wake-up path
[30]	I/O	gpio_wk30	Yes	Wake-up path
[29]	I/O	gpio_wk29	Yes	Wake-up path
[28:11]	I/O	gpio_[28:11]	Yes	GPIO
[10:6]	I/O	gpio_wk[10:6]	Yes	Wake-up path

<sup>(2)</sup> Only when the PER power domain is active

<sup>(3)</sup> The GPIO channel is not available on device pads. Reserved for internal use only (see the Comments column).

<sup>(4)</sup> The GPIO channel provides additional internal functionality (see the Comments column), besides its GPIO capabilities, when it is not connected to a pad of the device. That is, the corresponding pad is configured in a mode different from multiplexing Mode 3. For more information about pad configuration and multiplexing, see [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 18, Control Module](#).

<sup>(5)</sup> Only when the PER power domain is active

<sup>(6)</sup> The GPIO channel is not available on device pads. Reserved for internal use only (see the Comments column).

**NOTE:** The thermal shutdown comparator output signal (TSHUT) is an output from the BANDGAP module. This signal is low during normal operation and goes high during a thermal shutdown event. When channel 22 of the GPIO3 is not connected to a ball of the device (the corresponding pin is configured in a mode different from configuration mode 4; see [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 18, Control Module](#), for more information about pin configuration), TSHUT is connected to channel 22 of the GPIO3. An interrupt can be generated when a low-to-high transition occurs on TSHUT whether or not the interrupt generation for channel 22 of the GPIO3 is correctly configured.

**NOTE:** Channels 20 and 19 of GPIO6 are internally connected inside the device to the short detection (DPDM5VSHORT) and charger detection (CHGDETECT) outputs, respectively, of the USB OTG PHY module. This allows interrupt generation on the corresponding GPIO channel, if either of the mentioned events occurs.

### 25.4.8 General-Purpose Interface Data Input/Output Capabilities

The output-enable register (GPIOi.GPIO\_OE) controls the output/input capability of each pin. At reset, all the GPIO-related pins are configured as inputs, and their output capabilities are disabled. This register is not used within the module. Its only function is to carry the pad configuration.

When configured as an output (the desired bit reset in the GPIOi.GPIO\_OE register), the value of the corresponding bit in the GPIOi.GPIO\_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data-output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set and clear protocol register update feature. This feature gives the possibility to set or clear specific bits of this register with a single write access to the set-output data register (GPIOi.GPIO\_SETDATAOUT) or to the clear-output data register (GPIOi.GPIO\_CLEARDATAOUT) address (see Section 25.4.9, *General-Purpose Interface Set-and-Clear Protocol*). If the application uses a pin as an output and does not want interrupt/wake-up generation from this pin, the application must properly configure the wake-up enable (GPIOi.GPIO\_WAKEUPENABLE) and the interrupt enable (GPIOi.GPIO\_IRQSTATUS\_SET\_0 and GPIOi.GPIO\_IRQSTATUS\_SET\_1) registers.

When configured as an input (the desired bit is set to 1 in the GPIOi.GPIO\_OE register), the state of the input can be read from the corresponding bit in the GPIOi.GPIO\_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock. When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and to write data). If the application uses a pin as an input, the application must properly configure the wake-up enable (GPIOi.GPIO\_IRQWAKEN\_0 and GPIOi.GPIO\_IRQWAKEN\_1) and the interrupt enable (GPIOi.GPIO\_IRQSTATUS\_SET\_0 and GPIOi.GPIO\_IRQSTATUS\_SET\_0) registers to the interrupt and wake-up feature as needed. For using the alternate set and clear protocol, see Section 25.4.9, *General-Purpose Interface Set-and-Clear Protocol*.

### 25.4.9 General-Purpose Interface Set-and-Clear Protocol

#### 25.4.9.1 Description

The GPIO module implements the set-and-clear protocol register update for the following registers:

- GPIOi.GPIO\_DATAOUT
- GPIOi.GPIO\_IRQSTATUS\_CLR\_0
- GPIOi.GPIO\_IRQSTATUS\_CLR\_1
- GPIOi.GPIO\_IRQSTATUS\_SET\_0
- GPIOi.GPIO\_IRQSTATUS\_SET\_1
- GPIOi.GPIO\_IRQWAKEN\_0
- GPIOi.GPIO\_IRQWAKEN\_1

This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s). Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear: Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing a 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

### 25.4.9.2 Clear Instruction

#### 25.4.9.2.1 Clear Register Addresses

- Clear interrupt-enable registers (GPIOi.GPIO\_IRQSTATUS\_CLR\_0 and GPIOi.GPIO\_IRQSTATUS\_CLR\_1)  
A write operation in the GPIO\_IRQSTATUS\_CLR\_0 (or GPIO\_IRQSTATUS\_CLR\_1) register clears the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.  
A read of the clear interrupt enable0 (or enable1) register returns the value of the GPIO\_IRQSTATUS\_CLR\_0 (or GPIO\_IRQSTATUS\_CLR\_1) register
- Clear wake-up-enable registers (GPIOi.GPIO\_IRQWAKEN\_0 and GPIOi.GPIO\_IRQWAKEN\_1)  
A write operation in the clear wake-up-enable register clears the corresponding bit in the wake-up-enable register when the written bit is 1; a written bit at 0 has no effect.  
A read of the clear wake-up-enable register returns the value of the wake-up-enable register.
- Clear data-output register (GPIOi.GPIO\_CLEARDATAOUT)  
A write operation in the clear data-output register clears the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.  
A read of the clear data-output register returns the value of the data-output register.

#### 25.4.9.2.2 Clear Instruction Example

Assume the data-output register (or one of the interrupt/wake-up-enable register) contains the binary value, 0b0000 0001 0000 0001, and bit 0 is to be clear.

With the clear instruction feature, write 0b0000 0000 0000 0001 at the address of the clear data-output register (or at the address of the clear interrupt/wake-up-enable register). After this write operation, a reading of the data-output register (or the interrupt/wake-up-enable register) returns 0b0000 0001 0000 0000; bit 0 is cleared.

**NOTE:** Although the general-purpose interface registers are 32 bits wide, only the least-significant 16 bits are represented in this example.

Figure 25-13 shows an example of a clear instruction.

Figure 25-13. GPIO\_CLEARDATAOUT Register Example

### 25.4.9.3 Set Instruction

#### 25.4.9.3.1 Set Register Addresses

- Set interrupt-enable registers (GPIOi.GPIO\_IRQSTATUS\_SET\_0 and GPIOi.GPIO\_IRQSTATUS\_SET\_1)  
A write operation in the GPIOi.GPIO\_IRQSTATUS\_SET\_0 (or GPIOi.GPIO\_IRQSTATUS\_SET\_1) register sets the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.  
A read of the set interrupt enable0 (or enable1) register returns the value of the interrupt GPIOi.GPIO\_IRQSTATUS\_SET\_0 (or GPIOi.GPIO\_IRQSTATUS\_SET\_1) register.
- Set wake-up-enable registers (GPIOi.GPIO\_IRQWAKEN\_0 and GPIOi.GPIO\_IRQWAKEN\_1)  
A write operation in the set wake-up-enable register sets the corresponding bit in the wake-up-enable register when the written bit is 1; a written bit at 0 has no effect.

A read of the set wake-up-enable register returns the value of the wake-up-enable register.

- Set data-output register (GPIOi.GPIO\_SETDATAOUT)

A write operation in the set data-output register sets the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.

A read of the set data-output register returns the value of the data-output register.

### 25.4.9.3.2 Set Instruction Example

Assume the interrupt enable1 (or enable2) register (or the data-output register) contains the binary value, 0b0000 0001 0000 0000, and bits 15, 3, 2, and 1 are to be set.

With the set instruction feature, write 0b1000 0000 0000 1110 at the address of the set interrupt enable1 (or enable2) register (or at the address of the set data-output register). After this write operation, a reading of the interrupt enable1 (or enable2) register (or the data-output register) returns 0b1000 0001 0000 1110; bits 15, 3, 2, and 1 are set.

**NOTE:** Although the general-purpose interface registers are 32 bits wide, only the less-significant 16 bits are represented in this example.

Figure 25-14 shows an example of a set instruction.

**Figure 25-14. Write in GPIO\_IRQSTATUS\_SET\_0 Register Example**

gpio-011

The set wake-up-enable register offers the same feature with the wake-up-enable register.

## 25.5 General-Purpose Interface Programming Guide

### 25.5.1 General-Purpose Interface Low-Level Programming Models

#### 25.5.1.1 Global Initialization

##### 25.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the general-purpose interface module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the general-purpose interface. For more information, see [Section 25.3, General-Purpose Interface Integration](#), and [Section 25.2, General-Purpose Interface Environment](#).

**Table 25-11. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information about the module configuration, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Control module	Module specific pad muxing must be set in the control module. For more information about the module configuration, see <a href="#">Chapter 18, Control Module</a> .
MPU INTC	MPU INTC configuration must be done to enable the interrupts from the general-purpose interface module. See <a href="#">Chapter 17, Interrupt Controllers</a> .
DSP INTC	DSP INTC configuration must be done to enable the interrupts from the general-purpose interface module. See <a href="#">Chapter 17, Interrupt Controllers</a> .

##### 25.5.1.1.2 General-Purpose Interface Module Global Initialization

This procedure initializes the general-purpose interface module after a POR or software reset.

**Table 25-12. General-Purpose Interface Global Initialization**

Step	Register /Bit Field / Programming Model	Value
Execute software reset.	GPIO_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset completed?	GPIO_SYSSTATUS[0] RESETDONE	= 0x1
Configure idle mode.	GPIO_SYSCONFIG[4:3] IDLEMODE	0x–
Configure interface clock gating.	GPIO_SYSCONFIG[0] AUTOIDLE	0x–
Set clock gating power saving.	GPIO_LEVELDETECT0[31:0] LEVELDETECT0 and GPIO_LEVELDETECT1[31:0] LEVELDETECT1 and GPIO_RISINGDETECT[31:0] RISINGDETECT and GPIO_FALLINGDETECT[31:0] FALLINGDETECT	0x0000 00FF
Set clock gating ratio.	GPIO_CTRL[2:1] GATINGRATIO	0x–
Configure GPIO channels as input or output.	GPIO_OE[31:0] OUTPUTEN	0x–
Set debounce time value.	GPIO_DEBOUNCINGTIME[7:0] DEBOUNCETIME	0x–
Enable/disable debouncing for desired input line.	GPIO_DEBOUNCENABLE[7:0] DEBOUNCENABLE	0x–
<b>Interrupt and Wake-Up Request Configuration</b>		
Enable/disable interrupts.	GPIO_IRQSTATUS_SET_0[31:0] INTLINE and/or GPIO_IRQSTATUS_SET_1[31:0] INTLINE	0x–
Enable/disable wakeup for GPIO channels.	GPIO_IRQWAKEN_0[31:0] INTLINE and/or GPIO_IRQWAKEN_1[31:0] INTLINE	0x–
Enable/disable wake-up generation	GPIO_SYSCONFIG[2] ENAWAKEUP	0x1

## 25.5.1.2 General-Purpose Interface Operational Modes Configuration

### 25.5.1.2.1 General-Purpose Interface Read Input Register

**Table 25-13. General-Purpose Interface Read Input Register**

Step	Register /Bit Field / Programming Model	Value
Read input register value	GPIO_DATAIN[31:0] DATAIN	0x-

### 25.5.1.2.2 General-Purpose Interface Write Output Register

**Table 25-14. General-Purpose Interface Write Output Register**

Step	Register /Bit Field / Programming Model	Value
Write value to output register	GPIO_DATAOUT[31:0] DATAOUT	0x-

### 25.5.1.2.3 General-Purpose Interface Set Bit Function

**Table 25-15. General-Purpose Interface Set Bit Function**

Step	Register /Bit Field / Programming Model	Value
Write to set desired bit(s) in register	GPIO_SETDATAOUT[31:0] INTLINE	0x1
	GPIO_IRQSTATUS_SET_0[31:0] INTLINE	
	GPIO_IRQSTATUS_SET_1[31:0] INTLINE	
	GPIO_IRQWAKEN_0[31:0] INTLINE	
	GPIO_IRQWAKEN_1[31:0] INTLINE	

### 25.5.1.2.4 General-Purpose Interface Clear Bit Function

**Table 25-16. General-Purpose Interface Clear Bit Function**

Step	Register / Bit Field / Programming Model	Value
Write to clear desired bit(s) in register	GPIO_CLEARDATAOUT[31:0] INTLINE	0x1
	GPIO_IRQSTATUS_CLR_0[31:0] INTLINE	
	GPIO_IRQSTATUS_CLR_1[31:0] INTLINE	
	GPIO_IRQWAKEN_0[31:0] INTLINE	
	GPIO_IRQWAKEN_1[31:0] INTLINE	

## 25.6 General-Purpose Interface Register Manual

### 25.6.1 General-Purpose Interface Instance Summary

Table 25-17 summarizes the general-purpose interface instance.

**Table 25-17. Instance Summary**

Module Name	Base Address	Size
GPIO1	0x4A31 0000	4KB
GPIO2	0x4805 5000	4KB
GPIO3	0x4805 7000	4KB
GPIO4	0x4805 9000	4KB
GPIO5	0x4805 B000	4KB
GPIO6	0x4805 D000	4KB

### 25.6.2 General-Purpose Interface Registers

#### 25.6.2.1 General-Purpose Interface Register Summary

Table 25-18 summarizes the general-purpose interface GPIO1 to GPIO3 registers.

**Table 25-18. General-Purpose Interface GPIO1 to GPIO3 Registers Summary**

RESERVED																IDLEMODE	ENAWAKEUP	SOFTRESET	AUTOIDLE																																			

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Reserved	R	0x00000000
4:3	IDLEMODE	0x0: Force Idle: An idle request is acknowledged unconditionally. 0x1: No Idle: An idle request is never acknowledged. 0x2: Smart Idle: The acknowledgment to an idle request is given based on the internal activity (see 4.1.2). 0x3: Smart Idle Wake-up	RW	0x0
2	ENAWAKEUP	Wake-up control. 0x0: Wake-up generation is disabled. 0x1: Wake-up capability is enabled upon expected transition on input GPIO pin	RW	0
1	SOFTRESET	Software Reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal Mode 0x1: The module is reset.	RW	0
0	AUTOIDLE	OCP clock gating control. 0x0: Internal Interface OCP clock is free-running 0x1: Automatic internal OCP clock gating, based on the OCP interface activity	RW	0

## Keyboard Controller

---

---

---

This chapter describes the keyboard module of the device.

Topic	Page
<b>26.1 Keyboard Controller Overview .....</b>	<b>5142</b>
<b>26.2 Keyboard Controller Environment .....</b>	<b>5144</b>
<b>26.3 Keyboard Controller Integration .....</b>	<b>5147</b>
<b>26.4 Keyboard Controller Functional Description .....</b>	<b>5149</b>
<b>26.5 Keyboard Controller Programming Guide .....</b>	<b>5159</b>
<b>26.6 Keyboard Controller Register Manual .....</b>	<b>5163</b>

## 26.1 Keyboard Controller Overview

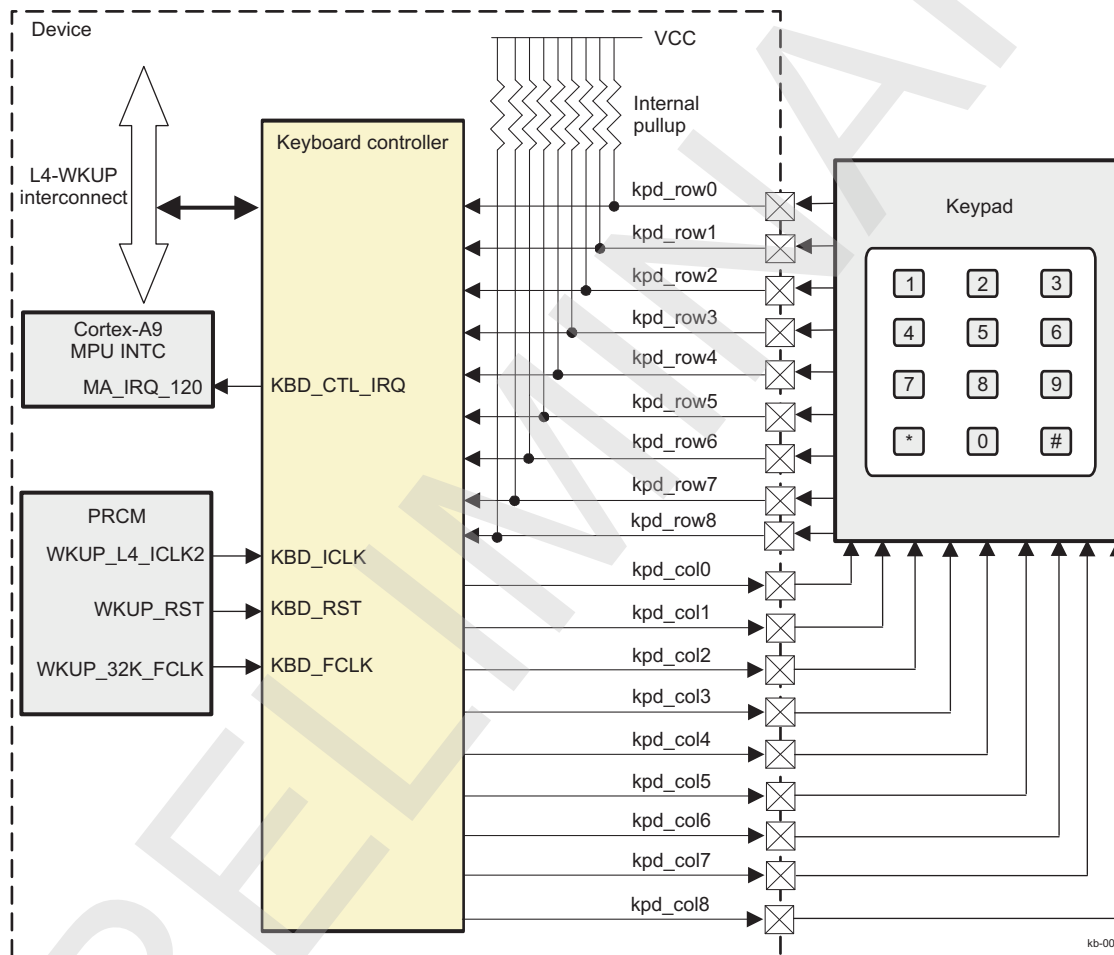

The keyboard controller implements a built-in scanning algorithm for hardware-based key-press decoding and reduces overhead in the microprocessor unit (MPU) software.

The keyboard controller includes a debouncing feature to ensure that only one key combination can be registered in the programmed time.

The keyboard controller can handle up to 9 × 9 keys, works on a 32-kHz clock, and can generate wake-up events when the chip is in sleep mode.

Figure 26-1 shows the keyboard controller.

**Figure 26-1. Keyboard Controller Overview**

The keyboard controller includes the following main features:

- Support of multiconfiguration keyboards up to 9 rows × 9 columns
- Each key coded on 1 bit in two 32-bit registers
- Long-key value or repeat timing reconfigurable on the fly
- Event detection on key press and key release
- Multikey-press detection and decoding
- Long-key detection on prolonged key press
- Integrated timer with four programmable comparison values
- Programmable time-out on permanent key press or after keyboard release
- Programmable interrupt generation on key events
- Software reset capability

- Read/write-posted register access modes
- 8-/16-/32-bit access supported on the level 4 (L4) interface
- 32-bit data bus
- 7-bit address bus

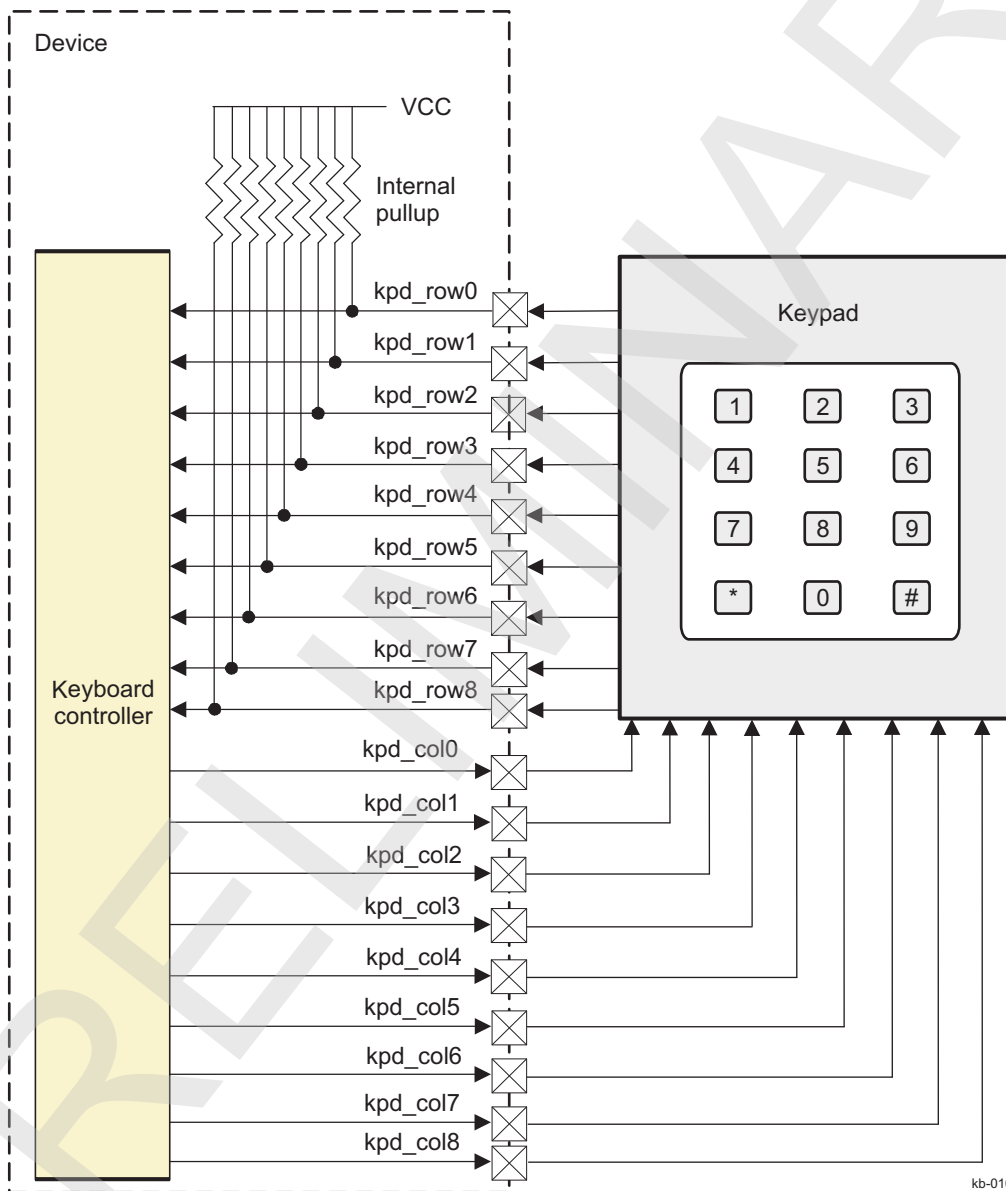

PRELIMINARY

## 26.2 Keyboard Controller Environment

The keyboard controller external interface pins map on the device pads when the device general-purpose input/output (GPIO) cells are configured and multiplexed for the keypad function by the control module. For more information, see [Section 18.4.8, PAD Functional Multiplexing and Configuration](#), and [Section 25.2.1, General-Purpose Interface as a Keyboard interface](#).

The external keypad typically connects directly to the keyboard controller of the device (see [Figure 26-2](#)).

**Figure 26-2. Typical Keyboard Environment**

### 26.2.1 Keyboard Controller Functions/Modes

The keyboard controller executes two functions:

- Key pad scanning and decoding for input of the external key presses. For more information, see [Section 26.4.6.4, Software Mode](#), and [Section 26.4.5, Keyboard Controller Hardware Decoding Modes](#).
- Device wake-up by interrupt request to the processor when a key is pressed and the device is in idle or sleep mode. For more information, see [Section 26.4.6, Keyboard Controller Interrupt Generation](#).

### 26.2.2 Keyboard Controller Signals

Table 26-1 describes the module signals and specifies their links to functions.

**Table 26-1. I/O External Keyboard Signals**

Signal	I/O <sup>(1)</sup>	Description	Reset Value	Function	Wake-Up Capability
kpd_row0	I	Keypad row 0 feed	HiZ (pulled up)	Key reading	Yes
kpd_row1	I	Keypad row 1 feed	HiZ (pulled up)	Key reading	Yes
kpd_row2	I	Keypad row 2 feed	HiZ (pulled up)	Key reading	Yes
kpd_row3	I	Keypad row 3 feed	HiZ (pulled up)	Key reading	Yes
kpd_row4	I	Keypad row 4 feed	HiZ (pulled up)	Key reading	Yes
kpd_row5	I	Keypad row 5 feed	HiZ (pulled up)	Key reading	Yes
kpd_row6	I	Keypad row 6 feed	HiZ (pulled up)	Key reading	Yes
kpd_row7	I	Keypad row 7 feed	HiZ (pulled up)	Key reading	Yes
kpd_row8	I	Keypad row 8 feed	HiZ (pulled up)	Key reading	Yes
kpd_col0	O	Keypad column 0 feed, active low	HiZ	Key reading	No
kpd_col1	O	Keypad column 1 feed, active low	HiZ	Key reading	No
kpd_col2	O	Keypad column 2 feed, active low	HiZ	Key reading	No
kpd_col3	O	Keypad column 3 feed, active low	HiZ	Key reading	No
kpd_col4	O	Keypad column 4 feed, active low	HiZ	Key reading	No
kpd_col5	O	Keypad column 5 feed, active low	HiZ	Key reading	No
kpd_col6	O	Keypad column 6 feed, active low	HiZ	Key reading	No
kpd_col7	O	Keypad column 7 feed, active low	HiZ	Key reading	No
kpd_col8	O	Keypad column 8 feed, active low	HiZ	Key reading	No

<sup>(1)</sup> I = Input; O = Output

### 26.2.3 Protocols and Data Formats

The keyboard controller detects and decodes multikey combinations using the following rules:

- Any 2-key combination is valid and can be decoded.
- Combinations using more than two keys are valid only if the rows and columns used do not cross over on another key to be detected. This is caused by equipotent propagation on a row/column (multikey limitations).

Figure 26-3 shows an example of multikey limitation.

**Figure 26-3. Multikey Limitation Example**

kb-007

**NOTE:** When using the keyboard controller with a smaller keypad (for example, 5 × 5), unused rows must be tied high to prevent disturbing the scanning process. Normally, all rows must be pulled up internally at the I/O cells of the device.

---

PRELIMINARY

### 26.3 Keyboard Controller Integration

Figure 26-4 shows keyboard controller integration.

Figure 26-4. Keyboard Controller Integration

The control module must enable the internal pullups of the GPIO cells for all keypad rows (for more information about configuration, see [Chapter 18, Control Module](#)).

[Table 26-2](#) through [Table 26-4](#) summarize the integration of the module in the device.

Table 26-2. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
KEYBOARD CONTROLLER	PD_WKUP	Yes	L4-WKUP

Table 26-3. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description

**Table 26-3. Clocks and Resets (continued)**

KEYBOARD CONTROLLER	KBD_FCLK	WKUP_32K_FCLK	PRCM	32-kHz functional clock. For information about power, reset, clock management (PRCM) clock gating and management, see <a href="#">Section 3.1.1.1.4, Clock Domain Level Clock Management</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
KEYBOARD CONTROLLER	KBD_ICLK	WKUP_L4_ICLK2	PRCM	L4-Interconnect interface clock. For information about PRCM clock gating and management, see <a href="#">Section 3.1.1.1.4, Clock Domain Level Clock Management</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
<b>Resets</b>				
KEYBOARD CONTROLLER	KBD_RST	WKUP_RST	PRCM	Active low asynchronous general reset. For information about PRCM reset sources and distribution, see <a href="#">Section 3.1.1.1.4, Clock Domain Level Clock Management</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .

**Table 26-4. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
KEYBOARD CONTROLLER	KBD_CTL_IRQ	MA_IRQ_120	Cortex-A9 INTC	Interrupt signal to the interrupt controller (INTC) of the MPU. For information about INTC interrupt control, see <a href="#">Chapter 17, Interrupt Controllers</a> .

**NOTE:**

- For the description of the interrupt source, see [Section 26.4.4, Interrupt Requests](#).

## 26.4 Keyboard Controller Functional Description

### 26.4.1 Keyboard Controller Block Diagram

Figure 26-5 shows the functional specification block diagram of the keyboard controller.

Figure 26-5. Keyboard Controller Block Diagram

kb-004

The keyboard controller detects events issued on any key of the connected keyboard and generates an interrupt to alert the host processor. The built-in hardware-scan algorithm decodes the pressed keys, including multikey combinations.

To reduce MPU software overhead, the hardware performs detecting and decoding in the keyboard controller state-machine. However, hardware decoding can be deactivated so that software handles the scanning algorithm.

The value of the columns output is determined in the [KBD\\_COLUMNOUTPUTS\[8:0\]](#) KBC\_REG bit field. To activate a key pad row-column connection, the corresponding bit must be 0b0.

The following sections describe subfunctions and subfunction interactions (control, data paths).

### 26.4.2 Keyboard Controller Software Reset

To perform a software reset, write 1 to the [KBD\\_SYSCONFIG\[1\]](#) SOFTRESET bit. The [KBD\\_SYSSTATUS\[0\]](#) RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the [KBD\\_SYSCONFIG\[1\]](#) SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before performing mailbox operations.

### 26.4.3 Keyboard Controller Power Management

[Table 26-5](#) describes the power-management features available for the keyboard controller module.

**NOTE:** For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.4, Clock Domain Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**Table 26-5. Local Power-Management Features**

Feature	Registers	Description
Clock autogating	<a href="#">KBD_SYSCONFIG[0]</a> AUTOGATING	This bit allows local power optimization in the module by gating the KBD_ICLK clock upon interface activity, or gating KBD_FCLK upon internal activity.
Slave idle modes	<a href="#">KBD_SYSCONFIG[4:3]</a> IDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	<a href="#">KBD_SYSCONFIG[9:8]</a> CLOCKACTIVITY	For configuration details, see <a href="#">Table 26-6</a> .
Master standby modes	N/A	N/A
Global wake-up enable	<a href="#">KBD_SYSCONFIG[2]</a> ENAWAKEUP	This bit enables the wake-up feature at the module level. If smart-idle mode is selected, this bit provides the option of smart-idle wake-up-capable mode.
Wake-up sources enable	<a href="#">KBD_WAKEUPENABLE</a>	This register holds one active-high enable bit per event source able to generate a wake-up signal.

[Table 26-6](#) lists the clock activity settings.

**Table 26-6. Clock Activity Settings**

<a href="#">KBD_SYSCONFIG[9:8]</a> CLOCKACTIVITY Values	Clock State When Module is in IDLE State		Features Available When Module is in IDLE State	Wake-Up Events
	KBD_ICLK	KBD_FCLK		
00	OFF	OFF	None	The wake-up capability of the module is disabled.
10	OFF	ON	All	Asserting of wake-up signal
01	ON	OFF	None	The wake-up capability of the module is disabled.
11	ON	ON	All	Asserting of wake-up signal

**CAUTION**

The PRCM module has no hardware means of reading the CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the keyboard controller CLOCKACTIVITY and keyboard controller clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**26.4.4 Keyboard Controller Interrupt Requests**

[Table 26-7](#) lists the event flags, and their mask, that can cause module interrupts.

**Table 26-7. Events**

Event Flag	Event Mask	Description
KBD_IRQSTATUS[3] MISS_EVENT	–	A miss event occurs.
KBD_IRQSTATUS[2] IT_TIMEOUT	KBD_IRQENABLE[2] IT_TIMEOUT_EN	A time-out event is detected.
KBD_IRQSTATUS[1] IT_LONG_KEY	KBD_IRQENABLE[1] IT_LONG_KEY_EN	A long-key event is detected.
KBD_IRQSTATUS[0] IT_EVENT	KBD_IRQENABLE[0] IT_EVENT_EN	An event is detected.

**26.4.5 Keyboard Controller Software Mode**

The KBD\_CTRL[1] NSOFTWARE\_MODE bit selects software mode when it is set to 0.

In software mode, the keyboard controller internal sequencer, which performs automatic scanning and decoding, is disabled. Consequently, the software must manually perform the scanning algorithm.

The scanning sequence is managed using the keyboard controller column outputs register (KBD\_COLUMNOUTPUTS) and the keyboard controller row inputs register (KBD\_ROWINPUTS). In this configuration, the keyboard interrupt is a logical ANDing of all bits of the keyboard controller row input register (KBD\_ROWINPUTS).

For more information about the software scan, see [Section 26.5.1.2.2, Keyboard Controller Basic Programming Model](#).

**26.4.6 Keyboard Controller Hardware Decoding Modes**

**26.4.6.1 Functional Modes**

When running in hardware(default) decoding mode (the KBD\_CTRL[1] NSOFTWARE\_MODE bit is set to 1), the keyboard controller offers several functional modes; these modes are summarized in [Table 26-8](#). The keyboard interrupt depends on the configuration in the keyboard controller interrupt-enable register (KBD\_IRQENABLE). If the event is enabled (bit 0 at 1), an interrupt is generated when the sequencer detects an event. Even if this interrupt is disabled, the flag status of the keyboard controller interrupt-status register (KBD\_IRQSTATUS) is updated.

**Table 26-8. Keyboard Controller Functional Modes**

Functional Mode	Associated Interrupt	Associated Timer Value	Description	Control
Keyboard event	Event interrupt	Debouncing value	Occurs when a key is pressed or released Always enabled	KBD_CTRL[8:5] bits must be set to 0 to disable all the other features.
Long key	Long-key interrupt	Long-key value	Used to detect a key that is pressed for a long time Should be associated with the long-key time-out functionality or repeat mode	KBD_CTRL[5] LONG_KEY bit

**Table 26-8. Keyboard Controller Functional Modes (continued)**

Functional Mode	Associated Interrupt	Associated Timer Value	Description	Control
Repeat key	Long-key interrupt	Long-key value	Generates an interrupt every long-key delay No time-out can be associated.	<a href="#">KBD_CTRL</a> [8] REPEAT_MODE bit
Empty time-out	Time-out interrupt	Empty time-out value	Interrupt generated if no key is pressed during an empty time-out period.	<a href="#">KBD_CTRL</a> [6] TIMEOUT_EMPTY bit
Long-key time-out	Time-out interrupt	Long-key time-out value	Associated with the long-key function Generated after a long-key interrupt if no event occurs during a long-key time-out period	<a href="#">KBD_CTRL</a> [7] TIMEOUT_LONG_KEY bit

Each mode can be activated/deactivated by setting the corresponding bits (5, 6, 7, and 8) in the [KBD\\_CTRL](#) register with the appropriate values (for more information, see [Section 26.6, Register Manual](#)).

### 26.4.6.2 Keyboard Controller Timer

As described in the previous section, each functional mode is associated with a timer value. Depending on the selected mode, the keyboard controller timer is loaded with the corresponding value as set in the related registers:

- [KBD\\_DEBOUNCINGTIME](#)
- [KBD\\_KEYLONGTIME](#)
- [KBD\\_TIMEOUT](#)

[Table 26-9](#) summarizes the keyboard controller timer values.

**Table 26-9. Keyboard Controller Timer Values**

Timer Value	Associated Register Field	Description
Debouncing time	<a href="#">KBD_DEBOUNCINGTIME</a> [5:0] DEBOUNCING_VALUE	To remove the effects of glitches when an event occurs on the keyboard, the controller waits for a debouncing period before taking a snapshot of the current state on the keyboard matrix. The timer is loaded with the debouncing time value after each detected event on the keyboard matrix. An event interrupt is generated after this delay.
Long-key time	<a href="#">KBD_KEYLONGTIME</a> [11:0] LONG_KEY_VALUE	This is the delay before generating a long-key interrupt after an event interrupt. If the long-key mode is selected, the timer is loaded with the long-key time value after an event interrupt is generated.  In repeat mode, the timer is reloaded with the same value after a long-key interrupt, and starts to count down again.
Long-key time-out	<a href="#">KBD_TIMEOUT</a> [15:0] TIMEOUT_VALUE	The timer is loaded with the time-out value and then a long-key interrupt is generated and starts to count down. When it reaches 0, a time-out interrupt is generated and the keyboard controller comes back to its IDLE state. This long-key time-out does not work in repeat mode.
Empty key time-out	<a href="#">KBD_TIMEOUT</a> [15:0] TIMEOUT_VALUE	The time-out interrupt occurs if no key is pressed during this delay. The keyboard controller then goes back to IDLE state.

The timer countdown period depends on three factors:

- The loaded value as set in:
  - [KBD\\_DEBOUNCINGTIME](#)
  - [KBD\\_KEYLONGTIME](#)
  - [KBD\\_TIMEOUT](#)
- The prescale clock timer value as set in the [KBD\\_CTRL](#)[4:2] PTV bit field. This programmable clock divider allows the reduction of the clock frequency used by the timer.
- The keyboard controller functional clock frequency (32 kHz)

The period is calculated as follows:

$$T_{\text{period}} = (T_{\text{value}} + 1) \times 2^{\text{PTV} + 1} \times T_{\text{clk}}$$

Where:

$T_{\text{value}}$  is the value stored in the [KBD\\_DEBOUNCINGTIME](#), [KBD\\_KEYLONGTIME](#), or [KBD\\_TIMEOUT](#) register.

PTV is the value of the [KBD\\_CTRL\[4:2\]](#) register PTV bit field.

$T_{\text{clk}}$  is the period of the 32-kHz functional clock; that is, 31.25  $\mu\text{s}$ .

The [KBD\\_CTRL\[4:2\]](#) PTV bit field determines the division factor of the timer clock. [Table 26-10](#) lists the divider rates.

**Table 26-10. Timer Prescale Values**

<a href="#">KBD_CTRL[4:2]</a> PTV Value	Divisor
0	2
1	4
2	8
3	16
4	32
5	64
6	128
7	256

**NOTE:** The timer minimum period is 62.5  $\mu\text{s}$ ; its maximum period is 524.288 s.

**CAUTION**

To prevent undefined results, the [KBD\\_CTRL\[4:2\]](#) PTV bit field must not be changed when the timer is running.

The timer value registers ([KBD\\_DEBOUNCINGTIME](#), [KBD\\_KEYLONGTIME](#), and [KBD\\_TIMEOUT](#)) can be updated at any time, whether or not the timer is running.. Nevertheless, the timer is updated only on the fly for the long-key time value. The new debouncing and time-out values are loaded only on the next load. Depending on the updated register, two cases can occur:

- The [KBD\\_KEYLONGTIME](#) register is updated; the new value stored in the [KBD\\_KEYLONGTIME](#) register is loaded into the timer when the register is written. If the timer is already counting down when [KBD\\_KEYLONGTIME](#) is updated, it counts down from the new value loaded in [KBD\\_KEYLONGTIME](#).
- The [KBD\\_DEBOUNCINGTIME](#) or [KBD\\_TIMEOUT](#) register is updated; the new value is considered only at the next timer load. If the timer is counting down when the registers are updated, the timer continues counting down from the previous value and is loaded with the new one on the next load.

Regardless of the timer state (stopped, counting down any of the values previously described, etc.), when a new event occurs on the keyboard, the timer is stopped and loaded with the debouncing time value. It then starts counting down.

**26.4.6.3 State-Machine Status**

To facilitate debugging, each state of the state-machine is coded in a register that indicates the current state of the machine. [Table 26-11](#) lists the corresponding codes.

**Table 26-11. State-Machine Values**

<a href="#">KBD_STATEMACHINE[3:0]</a> Value	Description
0x0	Idle
0x1	Scanning

**Table 26-11. State-Machine Values (continued)**

<b>KBD_STATEMACHINE[3:0] Value</b>	<b>Description</b>
0x2	Load timer debouncing
0x3	Test timer debouncing
0x4	Generated interrupt event
0x6	Load timer long key
0x7	Test timer long key
0x8	Generated interrupt long key
0x9	Load timer time-out
0xA	Test timer time-out
0xB	Generated interrupt time-out
0xF	Other

#### 26.4.6.4 Keyboard Controller Interrupt Generation

##### 26.4.6.4.1 Interrupt-Generation Scheme

The keyboard controller generates one interrupt signal to external INTC KBD\_CTL\_IRQ. Each functional mode generates dedicated interrupt events (logged in the [KBD\\_IRQSTATUS](#) register) that can be masked or unmasked using the [KBD\\_IRQENABLE](#) register.

The [KBD\\_IRQSTATUS](#) register is updated when the selected functional mode generates an interrupt event. However, the KBD\_CTL\_IRQ signal is asserted on the related event only when the corresponding bit is set in the [KBD\\_IRQENABLE](#) register.

---

**NOTE:** To reset the interrupt status bit, 1 must be written to the appropriate bit of the [KBD\\_IRQSTATUS](#) read/write register.

---

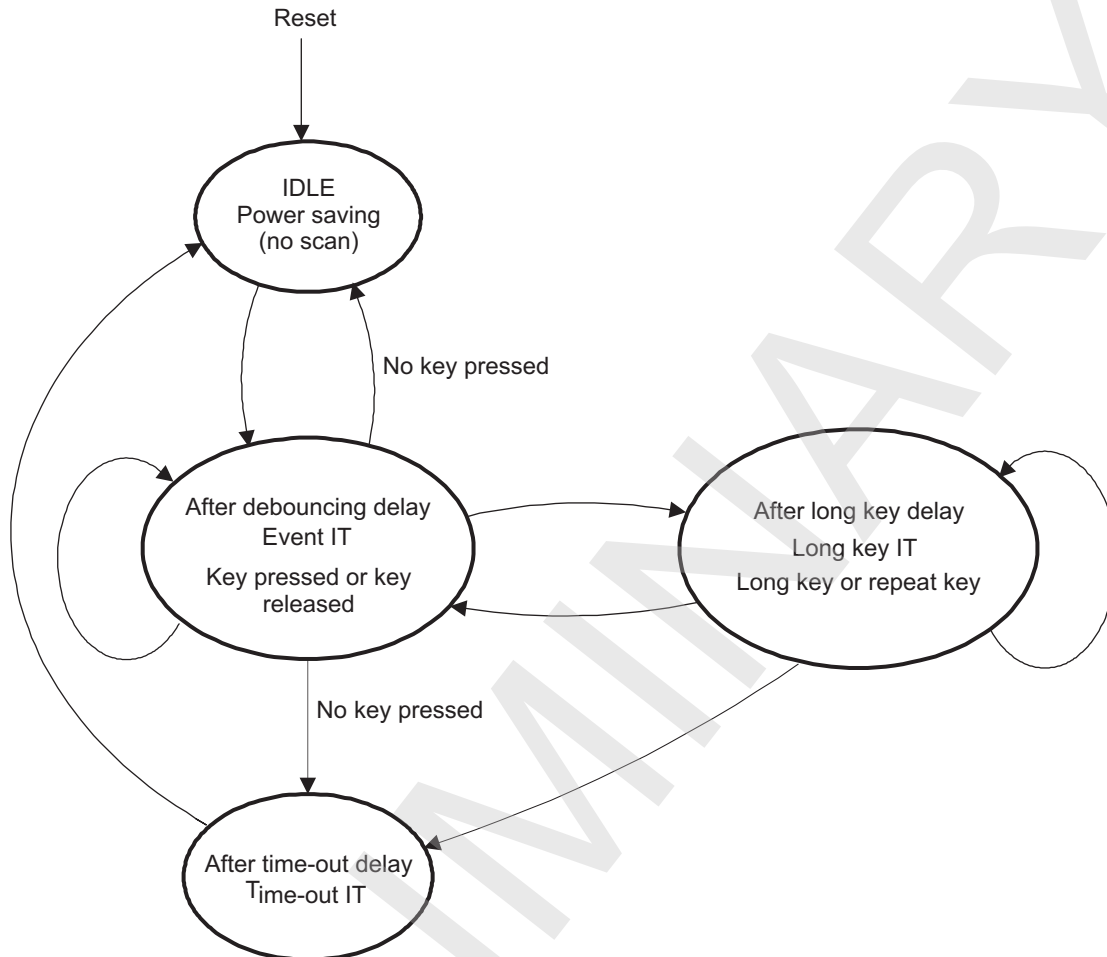

[Figure 26-6](#) shows the different interrupt events generated in each keyboard controller functional mode and details the relationships between them.

---

**NOTE:** Depending on the selected mode, some interrupt events cannot be generated.

---

Figure 26-6. Functional Modes and Related Interrupt Events

kb-005

While running in hardware-decoding mode, the keyboard controller performs automatic scans when not in IDLE state. When a key-press event occurs on the keyboard matrix, the keyboard controller leaves IDLE state and an interrupt event (the `KBD_IRQSTATUS[0]` IT\_EVENT bit) is set after the timer counts down the debouncing delay. An IT\_EVENT is generated when a key is pressed or released.

**NOTE:** An IT\_EVENT is generated regardless of the selected functional mode. If no time-out is set and no more keys are pressed, the keyboard controller goes back to IDLE state.

If long-key detection mode is set when the timer counts down the long-key delay, an interrupt long key (the `KBD_IRQSTATUS[1]` IT\_LONG\_KEY bit) is generated. If the repeat mode is set, the IT\_LONG\_KEY interrupt is generated periodically every long-key delay.

A time-out can also be set in event detection or long-key detection mode. In this case, a time-out interrupt (the `KBD_IRQSTATUS[2]` IT\_TIMEOUT bit) is generated after the time-out delay timer expires. After such an interrupt, the keyboard controller always goes back to idle.

**NOTE:** No time-out can be set in repeat mode. Only a keyboard event can stop the periodic interrupt generation.

### 26.4.6.4.2 Keyboard Buffer and Missed Events (Overrun Feature)

The keyboard controller has an overrun feature: A dedicated buffer allows the keyboard controller to memorize two successive events. If two successive events occur before a read is performed, the second event is stored and a second interrupt is generated when the first interrupt is cleared, allowing two key events to be received in a row.

If a third event occurs before the first event is treated, a missed event interrupt ([KBD\\_IRQSTATUS\[3\] MISS\\_EVENT](#) bit) is generated to report the lost event.

---

**NOTE:** The `MISS_EVENT` interrupt is not routed to the `KBD_CTL_IRQ` signal; the software must check the [KBD\\_IRQSTATUS\[3\] MISS\\_EVENT](#) bit to detect any missed events.

---

### 26.4.7 Keyboard Controller Key Coding Registers

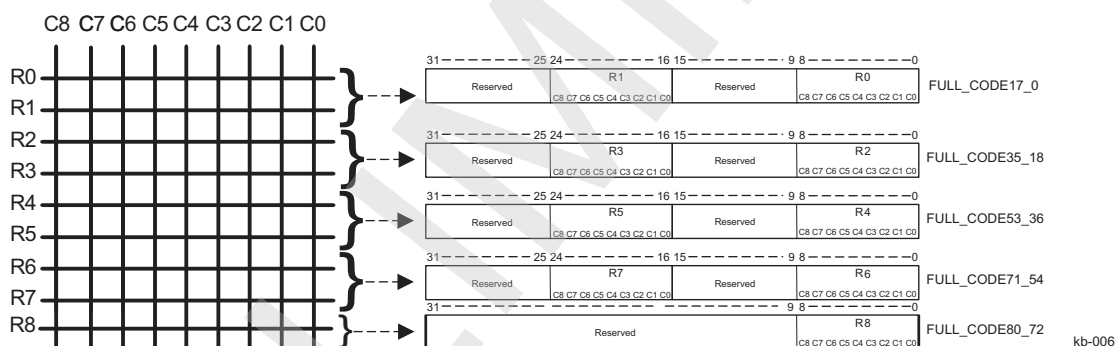

The keyboard controller matrix pressed keys state (indicating which columns/rows are connected) is reflected in the [KBD\\_FULLCODE17\\_0](#) up to [KBD\\_FULLCODE80\\_72](#) registers, as shown in [Figure 26-7](#). These registers are updated only when interrupt event status is inactive to prevent a lost event.

---

**NOTE:** The [KBD\\_FULLCODE31\\_0](#) and [KBD\\_FULLCODE63\\_32](#) registers, which are limited to supporting keyboards of a maximum 8 × 8 array size, can be used for back-to-back software compatibility.

---

**Figure 26-7. Key Coding Registers**

Each of the 9 × 9 keyboard size supporting registers ([KBD\\_FULLCODE17\\_0](#) up to [KBD\\_FULLCODE71\\_54](#)) stores the state of two keyboard rows. The [KBD\\_FULLCODE80\\_72](#) register stores the state of the last row, R8:

- The [KBD\\_FULLCODE17\\_0](#) register code rows 0, 1 (row 0 is coded between bits 0 and 8, row 1 is coded between bits 16 and 24)
- The [KBD\\_FULLCODE35\\_18](#) register code rows 2, 3 (row 2 is coded between bits 0 and 8, row 3 is coded between bits 16 and 24)
- The [KBD\\_FULLCODE53\\_36](#) register code rows 4, 5 (row 4 is coded between bits 0 and 8, row 5 is coded between bits 16 and 24)
- The [KBD\\_FULLCODE71\\_54](#) register code rows 6, 7 (row 6 is coded between bits 0 and 8, row 7 is coded between bits 16 and 24)
- The [KBD\\_FULLCODE80\\_72](#) register code row 8 (row 8 is coded between bits 0 and 8)

In each of these registers (excluding [KBD\\_FULLCODE80\\_72](#)):

- Bit 0 corresponds to column(0) – row (i) key, ..., bit 8 corresponds to column(8) – row(i) key.
- Bits from 9 to 15 are reserved.
- Bit 16 corresponds to column(0) – row(i+1) key, ..., bit 24 corresponds to column(8) – row(i+1) key.
- Bits 31 to 25 are reserved, where  $i = 0, 2, 4, 6$ .

In register [KBD\\_FULLCODE80\\_72](#) bit 0 corresponds to column(0) – row(8) key, ..., the bit 8 corresponds to column(8) – row(8) key, and the remaining bits (from 9 to 31) are reserved.

Each of the 8 × 8-keyboard size supporting registers ([KBD\\_FULLCODE31\\_0](#) and [KBD\\_FULLCODE63\\_32](#)) stores the state of four keyboard rows:

- The [KBD\\_FULLCODE31\\_0](#) register code rows 0, 1, 2, and 3 (row 0 is coded between bits 0 and 7, row 1 is coded between bits 8 and 15, row 2 is coded between bits 16 and 23, and row 3 is coded between bits 24 and 31)
- The [KBD\\_FULLCODE63\\_32](#) register code rows 4, 5, 6, and 7 (row 4 is coded between bits 0 and 7, row 5 is coded between bits 8 and 15, row 6 is coded between bits 16 and 23, and row 7 is coded between bits 24 and 31)

In these registers:

- [KBD\\_FULLCODE31\\_0](#)[0] corresponds to column(0) – row(0) key,..., [KBD\\_FULLCODE31\\_0](#)[7] corresponds to column(7) – row(0).
- [KBD\\_FULLCODE31\\_0](#)[8] corresponds to column(0) – row(1) key,..., [KBD\\_FULLCODE31\\_0](#)[15] corresponds to column(7) – row(1).
- [KBD\\_FULLCODE31\\_0](#)[16] corresponds to column(0) – row(2) key,..., [KBD\\_FULLCODE31\\_0](#)[23] corresponds to column(7) – row(2).
- [KBD\\_FULLCODE31\\_0](#)[24] corresponds to column(0) – row(3) key,..., [KBD\\_FULLCODE31\\_0](#)[31] corresponds to column(7) – row(3).
- [KBD\\_FULLCODE63\\_32](#)[0] corresponds to column(0) – row(4) key,..., [KBD\\_FULLCODE63\\_32](#)[7] corresponds to column(7) – row(4).
- [KBD\\_FULLCODE63\\_32](#)[8] corresponds to column(0) – row(5) key,..., [KBD\\_FULLCODE63\\_32](#)[15] corresponds to column(7) – row(5).
- [KBD\\_FULLCODE63\\_32](#)[16] corresponds to column(0) – row(6) key,..., [KBD\\_FULLCODE63\\_32](#)[23] corresponds to column(7) – row(6).
- [KBD\\_FULLCODE63\\_32](#)[24] corresponds to column(0) – row(7) key,..., [KBD\\_FULLCODE63\\_32](#)[31] corresponds to column(7) – row(7).

---

**NOTE:** The keyboard fullcode registers are not updated in software mode.

---

---

**NOTE:** When using a smaller keyboard (for example, 5 × 5 or 4 × 4), the bits of the unused columns/rows are not used either.

---

## 26.4.8 Keyboard Controller Register Access

### 26.4.8.1 Write Registers Access

The keyboard module uses a posted-write scheme to update any internal registers. This means the write transaction is immediately acknowledged on the L4-interface, although the effective write operation occurs later due to a resynchronization in the functional clock domain. This has the advantage of not stalling the interconnect system or the CPU that requested the write transaction. For each functional register, a pending bit is provided that is set if there is a pending write access to this register. The pending bits are accessible in the keyboard pending write register ([KBD\\_PENDING](#)).

In this mode, it is mandatory that the CPU checks the pending bits before any write access in the functional registers. In case a write is attempted to a register with a previous access pending, the previous access is discarded without notice (this can also lead to unexpected results).

A register read following a posted write (on the same register) may not read the previous write value if the write posted process is not complete. Software synchronization must be used to avoid noncoherent read.

This posted period is defined as the interval between the posted write access request and the reset of the pending bit in the [KBD\\_PENDING](#) register, and can be quantified:

$$T (\text{reset posted bit maximum}) = 3 * T_{\text{iclk}} + 3 * T_{\text{funcclk}}$$

The time it takes to accomplish the writing is:

$$T (\text{write accomplish maximum}) = 1 * T_{\text{iclk}} + 3 * T_{\text{funcclk}}$$

where:

Tickl is the L4-Interface clock period, and Tfuncclk is the functional clock period.

#### 26.4.8.2 Read Registers Access

The keyboard module uses a posted-read scheme for reading any internal register. The read transaction is immediately acknowledged on the L4-Interface. The value of the functional register to be read must be previously synchronized. This has the advantage of not stalling the interconnect system or the CPU that requested the read transaction.

The posted-read scheme can be used only if  $\text{Freq}(\text{KBD\_FCLK}) < \text{Freq}(\text{KBD\_ICLK})/4$ .

## 26.5 Keyboard Controller Programming Guide

### 26.5.1 Keyboard Controller Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

#### 26.5.1.1 Global Initialization

##### 26.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the keyboard module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the keyboard. For more information, see [Section 26.2, Keyboard Controller Environment](#), and [Section 26.3, Keyboard Controller Integration](#).

A description of the global initialization of surrounding modules is presented in [Table 26-12](#).

**Table 26-12. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
Power, reset, and clock management (PRCM)	The module interface (WKUP_L4_ICLK2) and functional (WKUP_32K_FCLK) clocks must be enabled. See <i>Clock Management Global Initialization</i> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a>
Interrupt controller of the Cortex-A9 MPU (INTC)	Interrupt request KBD_CTL_IRQ from the keyboard must be unmasked. For more information, see <a href="#">Chapter 17, Interrupt Controllers</a> .
Control module	The PAD CONFIG registers must be configured in to map the keyboard interface signals on the device pins through the multiplexers (mux mode 0 must be switched on) to determine the signal directions and to enable the internal pullups of the GPIO cells for all the keyboard rows. For more information about configuration, see <a href="#">Section 18.4.8, Pad Functional Multiplexing and Configuration</a> , and <a href="#">Section 25.2.1, General-Purpose Interface as a Keyboard interface</a> .

##### 26.5.1.1.2 Keyboard Controller Global Initialization

###### 26.5.1.1.2.1 Main Sequence – Keyboard Controller Global Initialization

This procedure initializes the keyboard controller after a POR or software reset (see [Table 26-13](#)).

**Table 26-13. Keyboard Controller Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Configure the parameters of the L4-Interface and enable the clock activity.	<a href="#">KBD_SYSCONFIG</a>	0x00000–
Configure the debouncing time of filtering the glitches on pressing or releasing key.	<a href="#">KBD_DEBOUNCINGTIME[5:0]</a> DEBOUNCING_VALUE	0x–
Configure the duration of a key press to allow shortcut detection (desired value of the long key interrupt or repeat mode value).	<a href="#">KBD_KEYLONGTIME[11:0]</a> LONG_KEY_VALUE	0x–
Configure the period of the long inactivity on the keyboard (desired value of the time-out interrupt).	<a href="#">KBD_TIMEOUT[15:0]</a> TIMEOUT_VALUE	0x–
Define the logical value of the column outputs (KEYPAD configuration) (logical 0 bit = active column-row).	<a href="#">KBD_COLUMNOUTPUTS[8:0]</a> KBC_REG	0x–
Perform the functional configuration of the keyboard module and the prescale clock timer value.	<a href="#">KBD_CTRL</a>	0x00000–
Clear the interrupt-status register.	<a href="#">KBD_IRQSTATUS</a>	0x0000000F
Enable (0b1)/disable (0b0) certain keyboard events for generating an Interrupt request.	<a href="#">KBD_IRQENABLE[2:0]</a> IT_..._EN	0x–
Unmask (0b1)/mask (0b0) the expected source of wake-up event that generates a wake-up request.	<a href="#">KBD_WAKEUPENABLE[2:0]</a> WUP_..._ENA	0x–

## 26.5.1.2 Operational Modes Configuration

### 26.5.1.2.1 Keyboard Controller in Hardware Decoding Mode (Default Mode)

#### 26.5.1.2.1.1 Main Sequence – Keyboard Controller Hardware Mode

After reset, all available functional modes are disabled, except detect-event mode, which is always active. [Table 26-14](#) describes the keyboard controller hardware mode.

**Table 26-14. Keyboard Controller Hardware Mode**

Step	Register/Bit Field/Programming Model	Value
Activate the internal keyboard controller sequencer by setting the bit.	<a href="#">KBD_CTRL</a> [1] NSOFTWARE_MODE	0b1
Select the functional mode by setting its corresponding bit to 1.	<a href="#">KBD_CTRL</a> [8:5]	0x–
Configure the duration of a key press to allow shortcut detection (desired value of the long key interrupt or repeat mode value).	<a href="#">KBD_KEYLONGTIME</a> [11:0] LONG_KEY_VALUE	0x–
Configure the period of the long inactivity on the keyboard (desired value of the time-out interrupt).	<a href="#">KBD_TIMEOUT</a> [15:0] TIMEOUT_VALUE	0x–
Configure the debouncing time of filtering the glitches on pressing or releasing key.	<a href="#">KBD_DEBOUNCINGTIME</a> [5:0] DEBOUNCING_VALUE	0x–
Clear the interrupt-status register.	<a href="#">KBD_IRQSTATUS</a>	0x0000000F
Enable (by writing 1)/disable (by writing 0) certain keyboard event for generating an Interrupt request	<a href="#">KBD_IRQENABLE</a> [2:0] IT_..._EN	0x–
Unmask (0b1)/mask (0b0) the expected source of wake-up event that generates a wake-up request.	<a href="#">KBD_WAKEUPENABLE</a> [2:0] WUP_..._ENA	0x–
Wait for the <a href="#">KBD_CTL_IRQ</a> interrupt signal assertion.		
Read the interrupt-status register to determine which event caused the interrupt.	<a href="#">KBD_IRQSTATUS</a>	
Read the <a href="#">KBD_FULLCODE17_0</a> to <a href="#">KBD_FULLCODE80_72</a> registers (or 8 × 8-keyboard-size-supporting <a href="#">KBD_FULLCODE31_0</a> and <a href="#">KBD_FULLCODE63_32</a> registers) to determine which key matrix combination was pressed.	<a href="#">KBD_FULLCODE17_0</a> [ROWi bits] (where i = 0 to 1) up to <a href="#">KBD_FULLCODE71_54</a> [ROWi bits] (where i = 6 to 7); <a href="#">KBD_FULLCODE80_72</a> [ROWi bits] (where i = 8); (or <a href="#">KBD_FULLCODE31_0</a> [j] FULL_CODE_31_0 and <a href="#">KBD_FULLCODE63_32</a> [k] FULL_CODE_63_32 bits (where j = 0 to 31, k = 32 to 63)	
Clear the corresponding bit(s) in the interrupt-status register by writing logical 1.	<a href="#">KBD_IRQSTATUS</a>	0x1

**NOTE:** The long-key detection mode and the repeat mode cannot be used simultaneously, because they share the same interrupt status bit and are mutually exclusive. Software must ensure that only one of these modes is selected at a time.

**NOTE:** All interrupts are disabled on reset

**NOTE:** When two events occur successively before the first event is read, the second interrupt is generated when the first interrupt is cleared. When more than two events in a row occur, the [KBD\\_IRQSTATUS](#)[3] MISS\_EVENT bit is set. Software must check this bit, which is not reflected on the [KBD\\_CTL\\_IRQ](#) line.

**NOTE:** The keyboard controller uses a posted-write scheme to update any internal register. Software must read the pending write status bits to ensure that the next write access is not discarded because of ongoing write synchronization. For more information, see [Section 26.4.8.1, Write Registers Access](#).

### 26.5.1.2.2 Keyboard Controller Software Scanning Mode

#### 26.5.1.2.2.1 Main Sequence – Keyboard Controller Software Mode

Table 26-15 contains a description of the keyboard controller software mode.

**Table 26-15. Keyboard Controller Software Mode**

Step	Register/Bit Field/Programming Model	Value D
Deactivate the internal keyboard controller sequencer by clearing the bit.	<a href="#">KBD_CTRL[1]</a> NSOFTWARE_MODE	0b0
Enable the event interrupt by setting the bit.	<a href="#">KBD_IRQENABLE[0]</a> IT_EVENT_EN	0b1
Wait for the KBD_CTL_IRQ interrupt signal assertion. Begin the software scan when the interrupt signal is asserted:		
1) Disable all columns to drive a logical 0 on the kpd_col[8:0] output by writing 0xFF. (logical 1 bit = inactive column-row)	<a href="#">KBD_COLUMNOUTPUTS[8:0]</a> KBC_REG	0xFF
2) Drive kpd_col(i) output, (where i = 0 to 8) , to 0 to capture a pressed-key-event, at the corresponding row input.	<a href="#">KBD_COLUMNOUTPUTS[i]</a> KBC_REG (where i = 0 to 8)	0b0
3) Read the KBR_LATCH bit field of the <a href="#">KBD_ROWINPUTS</a> register to determinate which is the pressed key. IF: KBR_LATCH k-bit = 0 , where k = 0 to 8 Then, the corresponding k-row is connected to the column being enabled. END IF	<a href="#">KBD_ROWINPUTS[8:0]</a> KBR_LATCH	
Repeat steps 2) and 3) for all existing columns.	<a href="#">KBD_WAKEUPENABLE[2:0]</a> WUP_..._ENA	0x–

**NOTE:** In software mode, during the manual keyboard scan, an interrupt is generated when a pressed key is detected.

#### 26.5.1.2.3 Using the Timer

For information about programming the keyboard controller timer, see [Section 26.4.6.2, Keyboard Controller Timer](#).

#### 26.5.1.2.4 State-Machine Status Register

To see the state of the state-machine, see [Section 26.4.6.3, State-Machine Status](#).

### 26.5.1.3 Keyboard Controller Events Servicing

Table 26-16 lists the keyboard controller event servicing.

**Table 26-16. Keyboard Controller Event Servicing**

Step	Register/Bit Field/Programming Model	Value
Clear all eventual previous indications of treated interrupts; write the IRQSTATUS register:	<a href="#">KBD_IRQSTATUS</a>	0x0000000F
Enable the desired sources of interrupt by writing in:	<a href="#">KBD_IRQENABLE</a>	0x0000000–
Unmask (enable) the desired sources of interrupt by writing logical 1 in the desired bit fields.	<a href="#">KBD_WAKEUPENABLE</a>	0x0000000–
When event occurs:		
Read the status register.	<a href="#">KBD_IRQSTATUS</a>	
IF: <a href="#">KBD_IRQSTATUS[3]</a> MISS_EVENT = 1	Start the interrupt handler for missed event.	

**Table 26-16. Keyboard Controller Event Servicing (continued)**

Step	Register/Bit Field/Programming Model	Value
ELSIF: <a href="#">KBD_IRQSTATUS[2]</a> IT_TIMEOUT = 1	Start the interrupt handler for timeout event.	
ELSIF: <a href="#">KBD_IRQSTATUS[1]</a> IT_LONG_KEY = 1	Start the interrupt handler for long key pressed event.	
ELSIF: <a href="#">KBD_IRQSTATUS[0]</a> IT_EVENT = 1	Start the interrupt handler for pressed key event.	
ENDIF		
Wait for the execution of the corresponding interrupt handler.	Interrupt controller of the MPU	
Clear the corresponding IRQ status register bits by writing of 1 there.	<a href="#">KBD_IRQSTATUS</a>	0x0000000-
Disable the corresponding sources of Interrupt if needed by writing of 0 at the corresponding bit fields.	<a href="#">KBD_IRQENABLE</a> or <a href="#">KBD_WAKEUPENABLE</a>	0x0000000-

## 26.6 Keyboard Controller Register Manual

### 26.6.1 Keyboard Controller Instance Summary

Table 26-17 summarizes the Keyboard Controller instances.

**Table 26-17. Keyboard Controller Instance Summary**

Module Name	Base Address	Size
Keyboard controller	0x4A31 C000	4KB

### 26.6.2 Keyboard Controller Registers

#### 26.6.2.1 Keyboard Controller Register Summary

Table 26-18 summarizes the keyboard controller register mapping.

**Table 26-18. Keyboard Controller Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Keyboard Controller L4-WKUP Base Address
KBD_REVISION	R	32	0x0000 0000	0x4A31 C000
KBD_SYSCONFIG	RW	32	0x0000 0010	0x4A31 C010

#### 26.6.2.2 Keyboard Controller Register Description

Table 26-19 through Table 26-59 describe the individual keyboard module registers.

**Table 26-19. KBD\_REVISION**

<b>Address Offset</b>	0x0000 0000	
<b>Physical Address</b>	See <a href="#">Table 26-18</a> .	<b>Instance</b> Keyboard Controller
<b>Description</b>	This register contains the IP revision code.	
<b>Type</b>	R	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP Revision	R	0x----- <sup>(1)</sup>

<sup>(1)</sup> TI internal data

**Table 26-20. Register Call Summary for Register KBD\_REVISION**

Keyboard Controller Register Manual

- [Keyboard Controller Register Summary: \[0\]](#)

**Table 26-21. KBD\_SYSCONFIG**

<b>Address Offset</b>	0x0000 0010	
<b>Physical Address</b>	See <a href="#">Table 26-18</a> .	<b>Instance</b> Keyboard Controller
<b>Description</b>	This register controls the various parameters of the L4-Interface.	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CLOCKACTIVITY	RESERVED	EMUFREE	IDLEMODE	ENAWAKEUP	SOFTRESET	AUTOGATING									

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Reads return 0.	RW	0x000000
9:8	CLOCKACTIVITY	<p>Clock(s) activity during wake-up mode period.</p> <p>0x0: Functional clock can be switched-off; L4-Interface clock can be switched-off.</p> <p>0x1: Functional clock can be switched-off; L4-Interface clock is maintained during wake-up period.</p> <p>0x2: Functional clock is maintained during wake-up period; L4-Interface clock can be switched-off.</p> <p>0x3: Functional clock is maintained during wake-up period; L4-Interface clock is maintained during wake-up period.</p>	RW	0x0
7:6	RESERVED	Write 0s for future compatibility. Reads return 0.	RW	0x0
5	EMUFREE	<p>Emulation mode</p> <p>0x0: The keyboard module is frozen in emulation mode (PINSUSPENDN signal active).</p> <p>0x1: The keyboard module runs free, regardless of PINSUSPENDN value.</p>	RW	0

Bits	Field Name	Description	Type	Reset
4:3	IDLEMODE	Power management, req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally. 0x1: No-idle. An idle request is never acknowledged. 0x2: Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module. 0x3: Reserved. Do not use.	RW	0x0
2	ENAWAKEUP	Wake-up feature global control 0x0: No wake-up line assertion in idle mode 0x1: Wake-up line assertion enabled in smart-idle mode	RW	0
1	SOFTRESET	Software reset. This bit is automatically reset by the hardware. During reads, it always return 0. 0x0: Normal mode 0x1: The module is reset.	RW	0
0	AUTOGATING	Internal L4-Interface clock gating strategy 0x0: L4-Interface clock is free-running. 0x1: Automatic L4-Interface clock gating strategy is applied, based on the L4-Interface activity.	RW	1

## Initialization

This chapter introduces the steps in the general-purpose (GP) device initialization.

Topic	Page
<b>27.1 Initialization Overview</b> .....	<b>5180</b>
<b>27.2 Preinitialization</b> .....	<b>5182</b>
<b>27.3 Reset Sequences</b> .....	<b>5197</b>
<b>27.4 Device Initialization by ROM Code</b> .....	<b>5198</b>
<b>27.5 Services for HLOS Support</b> .....	<b>5264</b>

## 27.1 Initialization Overview

This chapter provides an overview of the requirements for initializing the device from power-on to OS/application execution. It provides an overview of the overall initialization process, including hardware- and software-related steps, a general overview of the ROM code operational requirements, and the behavior expectations.

### 27.1.1 Terminology

- **Bootstrap:** Initial software launched by the ROM code during the memory booting phase
- **Configuration Header (CH):** Optional structure, that precedes the initial software and allows the redefinition of the ROM code default settings.
- **Downloaded software:** Initial software downloaded into the internal static RAM (SRAM) by the ROM code during the peripheral booting phase
- **eFuse:** A one-time programmable memory location usually set at the factory
- **Flash loader:** Downloaded software launched by the ROM code in preflashing. It also programs an image in external memories.
- **GP device:** General-purpose device
- **Initial software:** Software executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial software is a generic term for bootstrap and downloaded software.
- **Memory booting:** ROM code mechanism that consists of executing initial software from external memory
- **Master CPU:** The ARM Cortex™-A9 MPCore™ CPU for which CPU-ID is 0. It configures the multicore platform and starts the ROM code to ensure device booting from a mass storage memory (memory booting) or a peripheral interface (peripheral booting).
- **Peripheral booting:** ROM code mechanism that consists of polling selected interfaces, downloading, and executing initial software (in this case, downloaded software) in the internal RAM.
- **Permanent booting device:** Memory device containing, by default, the image to be executed during the booting sequence. It is the default memory booting device. The permanent booting device is used after warm reset if no software booting configuration is programmed.
- **Preflashing:** A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory
- **ROM Code:** The on-chip software in OMAP™ ROM that implements booting
- **Save-And-Restore (SAR RAM) memory:** On-chip RAM memory that is not cleared after warm resets or wake-ups from low-power modes
- **Slave CPU:** The ARM Cortex-A9 MPCore CPU for which CPU-ID is 1. It is brought to the wait-for-event (WFE) state by the ROM code, waiting to be woken up by the master CPU.
- **Software booting configuration:** A logical structure stored in the SAR memory that allows the redefinition of the ROM code default settings when booting after a warm reset

### 27.1.2 Initialization Process

Figure 27-1 is an overview of the initialization process and its steps:

- **Preinitialization:** Power, clock, and control connections must be present, and the boot configuration pins must be held at the desired logical levels.
- **Power/clock/reset ramp sequence:** Specific sequence that is applied by the power-management chip
- **ROM code:** Responsible for finding/downloading and for executing the initial software by using the master CPU
- **Initial software:** Software that prepares and passes control to application software or to the high-level operating system (HLOS)
- **Symmetric multiprocessing (SMP)-capable HLOS** or application (primarily for diagnostics)

Figure 27-1. Initialization Process

The first two steps in the initialization process are hardware-oriented; however, they require understanding of the process of configuring these system interface pins (balls on the device), which have software-configurable functionality. This configuration is an essential part of the chip configuration and is application-dependent. This chapter discusses these pins and the associated configuration registers that are vital to the correct initialization of the device.

## 27.2 Preinitialization

To accomplish a successful boot-up operation with a general-purpose (GP) device, certain hardware configuration settings must be in place. Clock, reset, and power connections, as well as pins involved in setting the boot memory space for the master CPU, must be connected and driven correctly for successful initialization of the device. The following sections describe the specific requirements for the preinitialization stage.

### 27.2.1 Power Requirements

The device can be supplied by an external power-management integrated circuit (IC). TI provides a global solution with the device connected to the TWL6030 power-management/TWL6040 audio codec IC.

[Figure 27-2](#) shows the power connections between the OMAP device and the TWL6030 power IC.

Figure 27-2. Power Supply Connections

init-002

**NOTE:** Figure 27-2 is an example of power connections between the device and the TWL6030. These connections depend on the actual application.

Table 27-1 describes the device power pins.

vdds_dv_bank7	Bank 7 of I/Os: KEYBOARD I/Os
vdds_dv_c2c	Chip-to-chip (C2C) I/Os
vdds_dv_fref	fref dual voltage I/Os: fref_clk[3:4]_out/fref_clk[3:4]_req
vdds_1p8_fref	Oscillator, slicer, fref_clk0_out, and fref_clk_ioreq

For more information about power management, see [Section 3.7 Power Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

The OMAP4430 power supply structure is based on the following constraints:

- Because most of the I/Os must be powered before the core, they are supplied on a specific rail (1.2 or 1.8 V).
- MPU, IVA/ABE, and Core are mapped on dedicated SMPS to allow independent SmartReflex dynamic frequency and voltage scaling for each of them.
- Because the DPLL, DSI, CSI, and USB OTG interfaces are noise-sensitive power domains, they are supplied by a dedicated rail to avoid other power sinks from affecting their power rail.
- Because bandgap, BodyBias LDOs, and SRAM LDOs must be supplied at 1.8 V from the beginning of the power-up sequence up to the end of power down, they are supplied by V1V8. This also applies to WKUP LDO at 1.2 V.
- Video DAC, eFuse VPP, SDMMC, and USB I/Os have specific requirements (sequencing, dual voltage, noise immunity, etc.) that require each of them be supplied by a dedicated power source.

## 27.2.2 Access to Power-Management IC

The ROM code accesses the power-management chip for the following purposes:

- SD/MMC1 powering:
  - The VMMC LDO is switched on by the ROM code when booting from the SD/MMC1 interface.

---

**NOTE:** The power supplies required for SD/MMC interface 2 are not controlled by the ROM code. It is assumed that the power-management chip (or the system hardware) properly powers the SD/MMC module attached to this interface.

---

- USB peripheral booting (internal or external transceiver):
  - PrevStartOk mechanism

This mechanism provides the ability to bypass the USB connection if a specific flag is set in the TWL6030 RTC domain (retained when the system is switched off).
- USB peripheral booting (internal transceiver):

- USB transceiver powering  
The TWL6030 VUSB LDO is turned on by the ROM code when selecting boot from the internal transceiver.
- VBUS detection  
The VBUS power pad is localized on the TWL6030 power IC. As a result, the ROM code must read from a TWL6030 register to get the status reflecting the device attachment to the USB link.
- Gating the TWL6030 USB charging circuitry during a suspend scenario  
If this event occurs, the ROM code should detect a suspend event and gate the charge circuitry inside the TWL6030.

### 27.2.2.1 Power-Management IC Detection

When booting from an SD/MMC card or USB internal transceiver (and only for these two booting options) the ROM code attempts to access the power device through the inter-integrated circuit (I<sup>2</sup>C™). The first access is a read transaction to obtain the TWL6030 version register. If this read access is successful (that is, the I<sup>2</sup>C transaction is acknowledged), the ROM code considers that a power-management device is attached, assuming it is TWL6030. The version value read is not used in any computation or compared to any hardcoded value.

If the first read transaction fails (that is, the I<sup>2</sup>C transaction times out or is not acknowledged), the ROM code logs it into a flag and does not try any further transaction until the next reset cycle. In this case, the nondetection of the companion chip does not block the boot process. However, the MMC card and USB boot procedures do not work as defined in this document:

- The ROM code does not ensure that the SD/MMC1 interface is powered when accessing the memory contents.
- The PrevStartOk mechanism is not functional (the specific flag is not checked).
- The peripheral booting from the internal USB transceiver is not possible, because the VBUS state read transaction is not performed. The USB (internal) device is skipped, and ROM code proceeds to the next device in the booting list.

### 27.2.2.2 Summary of the I<sup>2</sup>C Transactions

Nothing prevents the use of another power companion device together with the OMAP4430. However, special care must be taken if considering the two previously mentioned booting options (MMC/SD1 or USB internal transceiver). As a workaround solution, the alternative companion device can match (or emulate) the same register set and functionality as per TWL6030 for the following registers:

- JTAGVERNUM: Power-management IC detection. There must be a register at this location; however, its value is not used further by ROM code.
- PHOENIX\_SEQ\_CFG: The PrevStartOk flag is checked when performing USB peripheral boot (internal or external transceiver). If the flag is set, the USB peripheral booting procedure is skipped. In any case the full register is cleared (write 0x00) after the read transaction.
- VMMC\_CFG\_VOLTAGE: For the sake of powering the SDRAM1 card cage, the VMMC\_CFG\_VOLTAGE and VMMC\_CFG\_STATE registers are configured to set the VMMC LDO to 3 V. The value 0x15 is written to the VMMC\_CFG\_VOLTAGE register (selects 3-V output).
- VMMC\_CFG\_STATE: The value 0xE1 is written to the VMMC\_CFG\_STATE register (applies to all register groups, LDO state switched on).
- VUSB\_CFG\_VOLTAGE: The USB OMAP internal transceiver must be powered with a 3.3-V source to ensure its correct functionality. Three registers are used for this purpose. The VUSB\_CFG\_VOLTAGE register is written the value 0x18 for selecting 3.3 V.
- MISC2: The MISC2 register is written the value 0x08 for selecting the VBUS source.
- VUSB\_CFG\_STATE: The VUSB\_CFG\_STATE register is written the value 0xE1 for switching the VUSB LDO on for all register groups.
- CONTROLLER\_STAT1: VBUS detection is performed by reading the VBUS\_DET bit from the CONTROLLER\_STAT1 register. If this bit is set it reflects that a USB cable is plugged.
- CHARGERUSB\_CTRL1: This register is written the value 0x80 (SUSPEND\_BOOT = 1) for gating the charge circuitry when getting a USB SUSPEND event. If this bit is not set, the USB boot is aborted.

The complete description of TWL6030 register map can be found in TWL6030 documentation.

**NOTE:** No specific action is performed regarding the TWL6030 primary watchdog feature. In particular, if it is active (configurable in EEPROM) in the companion device, a system reset may occur before ROM code completes. The elapse value for the reset must be appropriately tuned so that the ROM code is not interrupted before the full platform start up (that is, before the initial software can take a specific action).

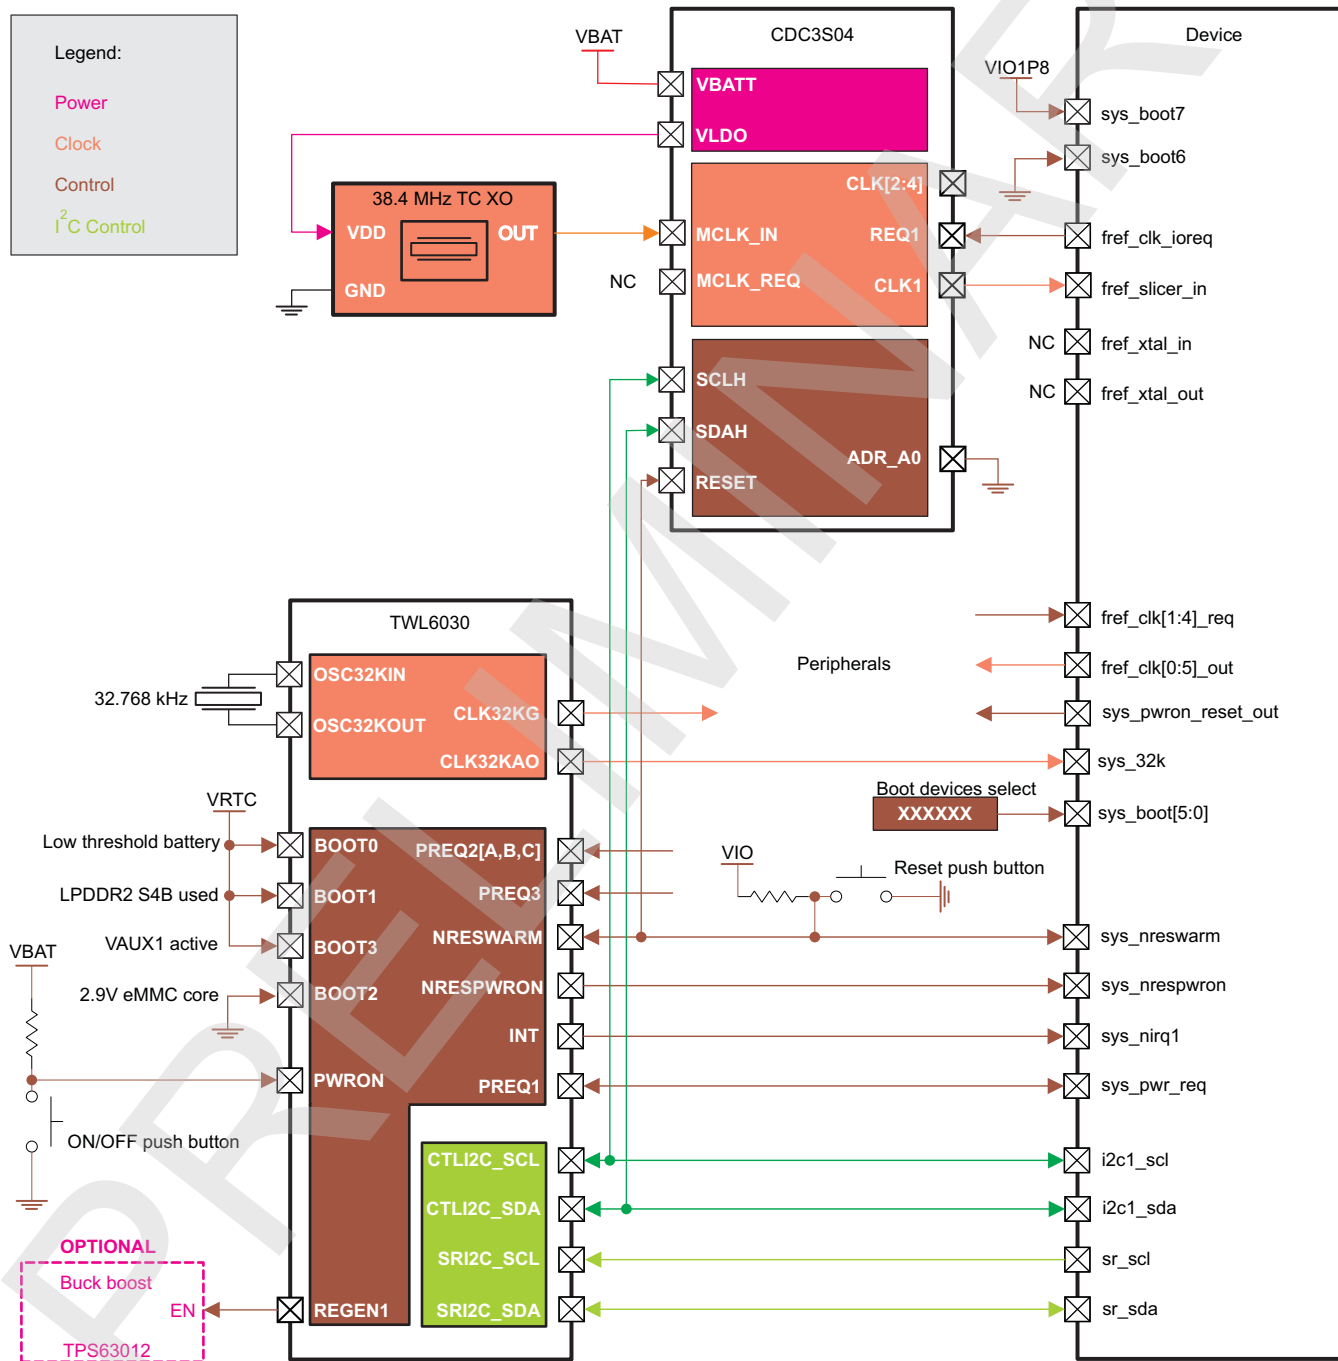

---

## 27.2.3 Clock, Reset, and Control

### 27.2.3.1 Overview

Figure 27-3 shows the clock and reset environment that gathers the clocks and reset-related signals at the system level, and the system-expansion signals.

Figure 27-3. Clock, Reset and Control Environment

init-004

The main features of the system interface are:

- A clock request output to an external clock source

- 12-, 16.8-, 19.2-, 26-, or 38.4-MHz reference clock input from external oscillator or clock supplied using internal crystal oscillator (up to 20 MHz)
- 32-kHz CMOS clock input
- Six configurable output clocks
- Eight input signals to define the boot mode and device system clock source
- Two reset sources
  - Power-on reset (POR) (cold reset)
  - Bidirectional warm reset

### 27.2.3.2 Clocking Scheme

#### 27.2.3.2.1 Required System Input Clocks

The device operation requires external input clocks, as follows:

- 32k-clock: A 32.768-kHz crystal is connected to the TWL6030 power device that embeds the 32k oscillator (a square CMOS clock can also be delivered on the 32k\_xtalin pin if the 32k crystal is connected on another device of the system). The resulting 32k-clock is delivered to the entire system on three outputs:
  - CLK32KAO\_is always on (meaning that when TWL6030 power VIO is on; that is, it is in WAIT-ON or ACTIVE state). It is used to deliver a 32k-clock to always-on features, such as the OMAP4430 and modem in the described system.
  - CLK32KG is software-controlled and is delivered when requested by the OMAP4430 (this input is on by default at platform boot).
  - CLK32KAUDIO is software-controlled and is delivered to the TWL6040 audio device (not shown in [Figure 27-3](#)) when requested by the OMAP4430 (this input is on by default at platform boot).
- High-speed clock: The platform high-speed (HS) low-jitter sine clock is provided by the clock driver (CDC3S04) to the TWL6040 audio IC, OMAP, and other peripherals requesting low-jitter sine clock (up to three outputs are available for peripherals). The OMAP device delivers digital clocks to other peripherals. The OMAP4430 supports different flavors of clock sources at several frequencies:
  - Crystal source. An internal oscillator embedded in the OMAP4430 is used. In this mode, the input clock is limited to 20 MHz by oscillator construction. The `fref_clk_ioreq` is then set as an input to be used by an external device to request the OMAP4430 to deliver the clock on `fref_clk0_out`. Pin `fref_slicer_in` can then be used to input an auxiliary clock (mainly for debugging purposes).
  - External oscillator type source. The internal OMAP4430 oscillator is disabled. The external source delivers a sine (slicer active) or square (slicer bypassed) single-ended clock on `fref_slicer_in` pin. The external source is enabled by the `fref_clk_ioreq` output. `fref_xtal_in` can then be used to input an auxiliary clock (oscillator-bypass mode).
- Audio clock: The TWL6040 audio device builds its own clock, either from the 32k clock or the HS clock (depending on the audio scenario). This internal clock is delivered to the OMAP4430 ABE subsystem (`abe_clks` input) for audio flow synchronization.

Clock input modes are selected by the `sysboot` pin (`sys_boot[6:7]`) to allow the system to wake up in the proper mode, even after a cold boot (selection of the relevant input pin (`fref_slicer_in` or `fref_xtal_in/out`) and slicer/oscillator mode setting (on or bypass)).

The OMAP4430 provides the HS clock to other devices through six `fref_clk[0:5]_out` pins.

TWL6040 audio device receives the HS clock on the MCLK pin when the audio scenario requires it (some low-power audio player scenarios can be performed only with the 32k-clock).

[Table 27-2](#) lists the mapping for the OMAP clock input sources. [Table 27-3](#) lists the TWL6030 clock requirements.

**Table 27-2. Mapping for Input Sources**

Input Source	Mapping	Frequency Range/List	Type
Internal oscillator	<code>fref_xtal_in/fref_xtal_out</code>	12, 16.8, or 19.2 MHz	Crystal connection balls
External HS clock	<code>fref_slicer_in</code>	12, 16.8, 19.2, 26, or 38.4 MHz	Sine or square single ended

**Table 27-2. Mapping for Input Sources (continued)**

Input Source	Mapping	Frequency Range/List	Type
External 32k-clock	sys_32k	32.768 kHz (nom.)	Square
TWL6040 audio IC	abe_clks	< 19.2 MHz	Square

**Table 27-3. TWL6030 Clock Requirements**

Input Source	Mapping	Frequencies Range/List	Type
Internal oscillator	OSC32KIN/OSC32KOUT	32.768 kHz (nom.)	Crystal connection pins

**CAUTION**

Clock configurations depend on core voltage, and maximum clock frequencies may not be applicable to production.

**27.2.3.2.2 Optional System Output Clocks**

The OMAP device can output six alternate clocks, `fref_clk[0:5]_out`. Output clocks 1 through 4 can be gated or enabled through associated clock-request signals, `fref_clk[1:4]_req`.

The clocks can be managed by software with the appropriate register in the power, reset, and clock management (PRCM) module. For more information, see [Section 3.3, PRCM Subsystem Environment](#).

**27.2.3.3 Reset Configuration****27.2.3.3.1 ON/OFF Interconnect and Power-On-Reset**

The entire system is typically awakened by an ON/OFF push button connected to the TWL6030 power IC. This signal belongs to the VBAT power domain and is active low (the TWL6030 internal pullup ties it to VBAT). Power up is propagated to the OMAP4430 through NRESPWRON/sys\_nrespwron signals when the TWL6030 power-up sequence is achieved. Because this signal is also provided to the TWL6040 audio IC, it resets its state-machine and gets some available functions even if V2V1 power supply is not provided.

**27.2.3.3.2 Warm Reset**

A warm reset can be asserted by the OMAP4430, by an external button (typically for development platform), or by any other device connected to it. It is mainly used to propagate the OMAP4430 internal reset to the whole platform to set it to a known state.

The OMAP4430 releases `sys_nreswarm` after NRESPWRON is deasserted.

**27.2.3.3.3 Peripheral Reset by sys\_pwron\_reset\_out**

`Sys_pwron_reset_out` is provided to the system by the OMAP4430 to power on and/or deactivate the reset of system peripherals. This signal is activated by SCRMP during the power-up sequence a few milliseconds after the default-on clocks (OMAP4430 – `fref_clk4_out` and CDC3S04 – `CLK[1:4]`) are stabilized. This allows switching on peripherals that require synchronous reset.

`Sys_pwron_reset_out` is controllable by software when the system is on. It is not affected by a warm reset.

**27.2.3.3.4 Peripheral Reset by GPIO**

Most of the peripherals are reset/power on/off by GPIO. By default, under POR, most OMAP4430 signals are in safe mode with a default value driven by the I/O cell. The value is driven by an internal pullup or pulldown. Depending on the peripheral reset active level, users must select one GPIO or another (according to the reset value).

Once POR is released, the value on the pad is driven by the default configuration of control module. Most of time, this configuration is aligned with the default value selected on the I/O cell.

The next step is application-dependent: Users must configure the OMAP4430 registers to validate GPIO use and the default configuration of the control module.

### 27.2.3.3.5 Warm Reset Impact on GPIOs

When a warm reset event occurs:

- The GPIO controller is reset. Consequently, the GPIO is automatically turned in input mode.
- The control module, which is part of the wake-up domain, is not reset. Information related to signal multiplexing mode and pullup or pulldown configuration is still valid.

Therefore, when a warm reset event happens, the output buffer is disabled and the selected pull is activated. Consequently, two different behaviors can be defined with regard to what is expected by the platform:

- GPIO sensitive to warm reset:  
To avoid getting a floating signal during (and after) a warm reset event, users need to select a pullup or pulldown (depending on the reset value of the peripheral) and enable the pull. Pull activation does not affect overall leakage when the GPIO buffer is driving because the pull is disconnected at that time.
- GPIO not sensitive to warm reset:  
To avoid getting a floating signal during (and after) a warm reset event and to keep the same value that was driven before the reset, users must align the pull value with the drive value each time there is an access to a dedicated GPIO register. This activation of the pull does not affect the overall leakage when the GPIO buffer is driving because the pull is disconnected at that time.

---

**NOTE:**

- For more information about device reset management, see [Section 3.5, Reset Management Functional Description](#).
  - To determine the cause of the last reset, see [Section 3.5.5, Reset Logging](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- 

### 27.2.3.4 TWL Power/Audio Devices Control

- I<sup>2</sup>C:  
The TWL6030 power and TWL6040 audio devices are controlled by the OMAP4430 I2C1 (HS I<sup>2</sup>C). Some internal pullup resistors are provided by the OMAP4430 (different values can be selected to adapt the I/O buffer strength to the bus topology). The I<sup>2</sup>C links must first be started in fast-speed mode. Therefore, the buffer default pullup value must support this mode.
- SmartReflex control:  
Some of the TWL6030 power resources are controlled through SmartReflex link (I<sup>2</sup>C-like). This control allows the host to drive the dynamic-frequency voltage scaling (DVFS) and adaptive voltage scaling (AVS) operations of these resources. As with its I<sup>2</sup>C interfaces, some internal pullup resistors are provided on the OMAP4430 SmartReflex I/Os. The link must be run at the highest speed allowed by the voltage controller of the OMAP4430 (lower than I<sup>2</sup>C HS mode frequency). For example, this frequency must be 1.82 MHz with a 38.4-MHz system clock.
- INT:  
Both devices can activate the INT signal at any time when they require the host device to monitor their activity. When receiving such an interruption, the OMAP4430 checks, through the I<sup>2</sup>C, to determine the source of the interrupt. These INT pins are active low.
- Sys\_pwr\_req:  
When exiting off mode, the OMAP4430 ties up the sys\_pwr\_req pin to wake up the TWL6030 power application group.

### 27.2.3.5 TWL6030 Power Request Signals

The TWL6030 power-management IC drives three external enable-output signals. This allows switching on some external resources at different stages of the power-up sequence:

- REGEN1/2 are driven high at the beginning of the power-up sequence, before any internal power source is turned on. They belong to the VBAT power domain. REGEN1 can typically be used for buck boost control.
- SYSEN is driven high immediately after the VMEM power output is turned on. It allows switching on an additional regulator in case the VMEM power regulator does not support the current requirements of memory. SYSEN belongs to the VIO power domain.

TWL6030 power also receives five power resource requests: PREQ[1, 2A, 2B, 2C, 3]. These pins allow an external device to request TWL6030 power internal resources. TWL6030 power behavior when pins are activated must be programmed after the first boot (resources and PREQ pins allocated by group, resource behavior upon group activation, etc.). The typical PREQ allocation per group is:

- PREQ1: Application group. Connected to OMAP.
- PREQ2A, PREQ2B, and PREQ2C: Peripheral group. Connected to peripherals A, B, and C (for instance, BT/FM/GPS/WLAN device, Wimax device, W-USB device)
- PREQ3: Modem group

---

**NOTE:** Powering the clock driver requires PREQ assertion. Therefore, it is advised to connect any peripheral receiving a clock from CDC3S04 to one PREQ.

---

The use of PREQ[1:3] is especially required when TWL6030 power is in sleep mode, because it cannot handle an I<sup>2</sup>C command. Any device that requires the TWL6030 resource to wake up must first activate its associated PREQ. All TWL6030 power regulators are off or in sleep mode when TWL6030 power is in sleep mode.

PREQ1 is used by OMAP when waking up from off mode to wake up the TWL6030.

### 27.2.4 Boot Configuration

Six external pins (sys\_boot[5:0]) are used to select interfaces or devices for the booting list. The sys\_boot[7:6] pins select the OMAP clock source configuration.

All eight pins are sampled and latched onto the SYSCTRL\_GENERAL\_CORE.CONTROL\_STATUS[7:0] SYS\_BOOT register bit field after POR. After booting, these pins can be used for other functions such as GPIOs, and the associated register bit field is not updated by the new functionality. See [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), for more information about pad multiplexing configuration.

---

**NOTE:**

- If used as GPIOs, sys\_boot[7:0] pins must be used only in output mode to ensure that the input values are selected by the pullups and pulldowns after a POR/warm reset.
  - Care must be taken when choosing to use sys\_boot[7:6] pins as GPIOs because these pins have no internal pullup or pulldown capability.
- 

#### 27.2.4.1 Clock Source Selection

OMAP4430 clock source settings:

- sys\_boot[7:6] = 0b00:
  - The system clock source is the on-chip oscillator.
  - The slicer is powered down and its input can be used to provide the OMAP with an alternate clock.
  - Fref\_clk\_ioreq is a clock request input associated to fref\_clk0\_out by default.
- sys\_boot[7:6] = 0b01:
  - The system clock source is external. The internal oscillator is bypassed to inject the system clock.
  - The slicer is powered down and the slicer input can be used to provide the chip with an alternate clock.
  - The Fref\_clk\_ioreq signal is an output that requests the clock to the external clock supplier

- `sys_boot[7:6] = 0b10:`
  - The system clock source is the on-chip slicer, supplied by an external oscillator. The internal oscillator is powered down and the input can be configured to supply the alternate system clock to OMAP.
  - The slicer is active.
  - The `Fref_clk_ioreq` signal is an output that requests the clock from the external clock supplier.
- `sys_boot[7:6] = 0b11:`
  - The system clock source is external. The internal oscillator is powered down and the input can be configured to supply the alternate system clock to the OMAP device.
  - The slicer is bypassed to inject the system clock.
  - The `Fref_clk_ioreq` signal is an output that requests the clock from the external clock supplier.

#### 27.2.4.2 Booting Device Order Selection

The ROM code creates the device list (order) based on information gathered from two locations.

- The first location is the software booting configuration stored in the nonvolatile save-and-restore (SAR) memory, and used after warm resets.
- The second location is the `sys_boot[5:0]` external configuration pins sensed in the control module. The SYSBOOT pins are used to index a booting device list from a table with possible booting scenarios. The order of examined booting devices is from the first to the fourth devices.

The following names are used in the tables:

- Memory types:
  - Execute in place (XIP): XIP memory without wait-signal monitoring enabled (NOR flash memory or other XIP device)
  - XIP wait: XIP memory with wait-signal monitoring
  - NAND: NAND flash memories (non-XIP)
  - OneNAND: OneNAND and Flex-OneNAND flash memories
  - EMIF: LPDDR2-NVM device
  - MMC1: MMC/SD card or eMMC/eSD™ device (SD/MMC port 1)
  - MMC2(1): eMMC or eSD memory device, first option (SD/MMC port 2). See [Section 27.2.4.3, Boot Peripheral Pin Multiplexing](#).
  - MMC2(2): eMMC or eSD memory device, second option (SD/MMC port 2). See [Section 27.2.4.3, Boot Peripheral Pin Multiplexing](#).
- Peripheral interfaces:
  - USB: USB A0 from OMAP internal transceiver (USBPHY)
  - USB-ULPI: USB A0 from external transceiver through ULPI interface
  - Universal asynchronous receiver/transmitter (UART): UART3 interface
- Permanent booting devices listed in [Table 27-4](#) are in **bold**.

---

**NOTE:** Only permanent booting devices (in bold) are put on in the list in case of a warm reset, and the device list is taken from the `sys_boot` pins. As a result, peripheral booting devices are skipped when the OMAP4430 restarts from warm resets.

---

Users can force the execution of the peripheral booting procedure after warm reset by using the software booting configuration feature.

[Table 27-4](#) lists the booting device order when it is preferred to boot from a memory type device. This table is selected by ROM code when `sys_boot5` pin is tied high (= 1) after reset and before booting completion. If fast XIP booting is selected, the `sys_boot5` pin controls the XIP wait-signal monitoring (that is, a logical high level enables wait-signal monitoring).

**Table 27-4. Memory Preferred Booting**

sys_boot[5:0]	Booting Devices Order			
	1 <sup>st</sup>	2 <sup>nd</sup>	3 <sup>rd</sup>	4 <sup>th</sup>
0b100000	<b>MMC2(1)</b>	USB		
0b100001	<b>XIP</b>	USB		
0b100010	<b>XIPWAIT</b>	USB		
0b100011	<b>NAND</b>	USB		
0b100100	<b>EMIF</b>	USB		
0b100101	<b>MMC1</b>	USB		
0b100110	<b>OneNAND</b>	USB		
0b100111	<b>OneNAND</b>	<b>MMC2(1)</b>	USB	
0b101000	<b>MMC2(1)</b>	UART		
0b101001	<b>XIP</b>	UART		
0b101010	<b>XIPWAIT</b>	UART		
0b101011	<b>NAND</b>	UART		
0b101100	<b>EMIF</b>	UART		
0b101101	<b>MMC1</b>	UART		
0b101110	<b>OneNAND</b>	UART

<sup>(1)</sup> Only on GP devices

### 27.2.4.3 Boot Peripheral Pin Multiplexing

Table 27-6 lists the code pin multiplexing configuration supported by ROM according to boot peripheral.

**Table 27-6. Pin Multiplexing According to Boot Peripheral**

Boot Device	Boot Interface	Pins
NAND/OneNAND	GPMC	GPMC pins in mux mode 0, CS0, WAIT0
XIP memory	GPMC	GPMC pins in mux mode 0, CS0, WAIT0
MMC/SD/eMMC/eSD	SDMMC1	SDMMC1 pins in mux mode 0
eMMC/eSD	SDMMC2 (option 1) SDMMC2 (option 2)	GPMC pins in mux mode 1 SDMMC5 + FREF_CLK pins, all in mux mode 5
LPDDR2-NVM	EMIF1	LPDDR21 pins in mux mode 0, CS1
UART	UART3	UART3 pins in mux mode 0

**Table 27-6. Pin Multiplexing According to Boot Peripheral (continued)**

Boot Device	Boot Interface	Pins
USB from internal transceiver	HSUSBOTG (USBA0-USBPHY)	USBA0_OTG pins in mux mode 0
USB from external transceiver	HSUSBOTG (USBA0-ULPI)	DPM_EMU[2:13] pins in mux mode 1

**NOTE:** The ROM code examines the interfaces that are selected to be searched until a valid bootable interface/device is found. The activities on the pins of the failed interfaces must be considered in case they are connected to any other peripherals for any other purposes (for example, an LED connected to a GPMC pin muxed internally to a GPIO).

### 27.3 Reset Sequences

For the description of the reset sequences, see [Section 3.5.6, Reset Sequences](#), in [Section 3.5, Reset Management Functional Description](#).

## 27.4 Device Initialization by ROM Code

This section describes high-level booting concepts and provides basic knowledge for booting on the device.

### 27.4.1 Booting Overview

#### 27.4.1.1 Booting Types

Bootting is the process of starting a bootstrap from one of the booting devices.

The ROM code has two functions for booting: Peripheral booting and memory booting.

- In peripheral booting, the ROM code polls a selected communication interface such as UART or USB, downloads the executable code over the interface, and executes it in internal RAM. Downloaded software from an external host can be used to program flash memories connected to the device. This special case of peripheral booting is called preflashing; software downloaded for preflashing is called the flash loader. The flash loader burns a new client application image in external flash memory. Initial software is a generic term for bootstrap, downloaded software, and flash loader. After the image is burnt, a software (warm) reset can be performed.
- In memory booting, the ROM code finds the bootstrap in permanent memories such as flash memory or memory cards and executes it. This process is normally performed after a cold or warm device reset.

The ROM code detects whether the device should download software from a peripheral interface (USB or UART) by using the `sys_boot[5:0]` pin configuration. This mechanism encompasses initial flashing in production (external memory is empty) and reflashing in service (external memory is already programmed).

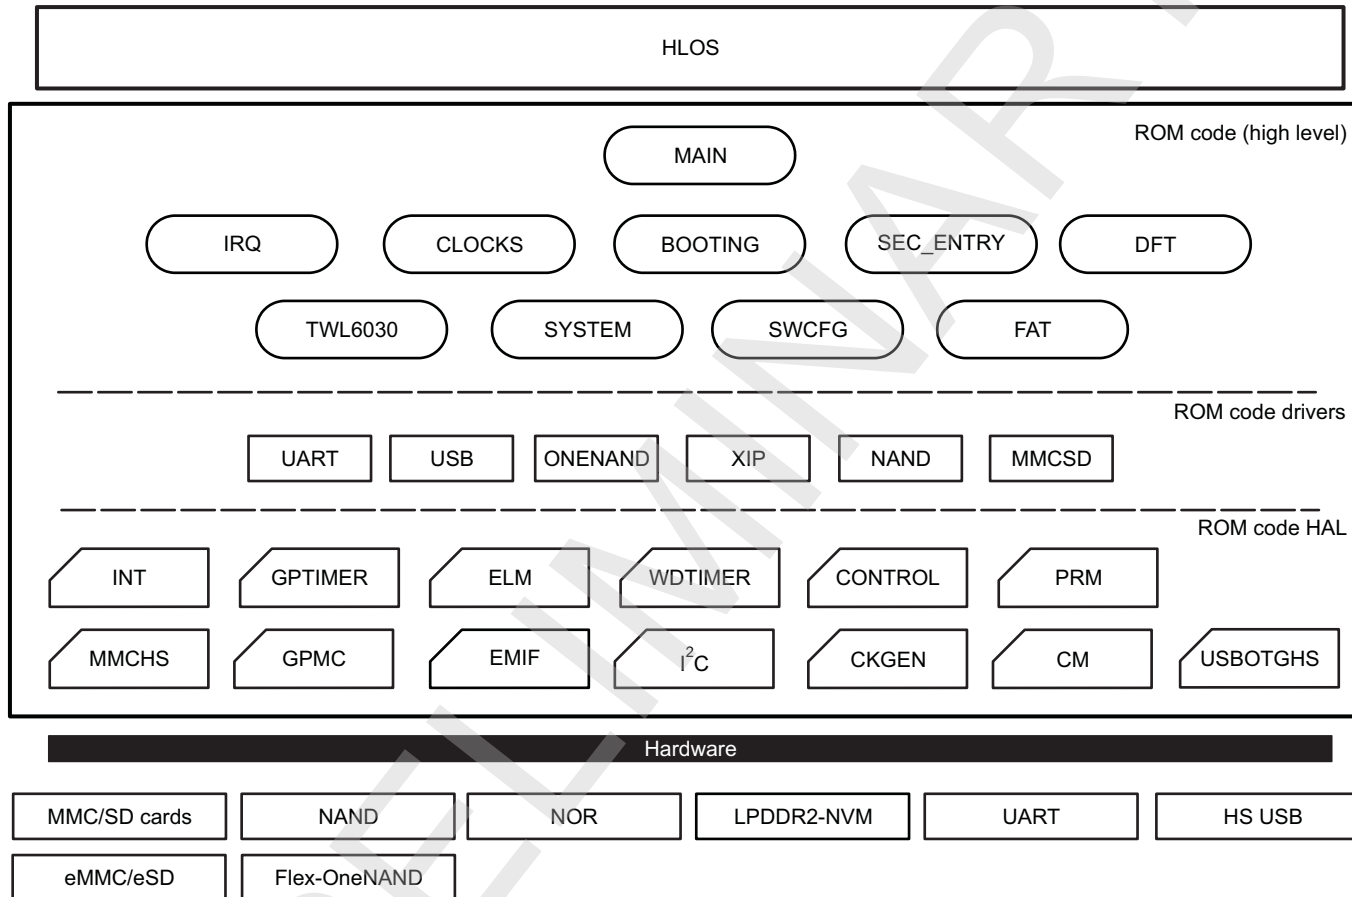

#### 27.4.1.2 ROM Code Architecture

Figure 27-4 shows the ROM code architecture. It is split into three main layers with a top-down approach: high-level, drivers, and hardware abstraction layer (HAL). One layer communicates with a lower-level layer through a unified interface.

- The high-level layer performs the main tasks of the public ROM code: multicore startup, watchdog and clock configurations, interrupt management, interaction with the power-management IC, and main booting routine.
- The driver layer implements the logical and communication protocols for any booting device in accordance with the interface specification.
- The HAL implements the lowest level code for interacting with the hardware infrastructure IPs. End booting devices are attached to the device I/O pads.

Figure 27-4 shows the three layers with their modules.

Figure 27-4. ROM Code Architecture

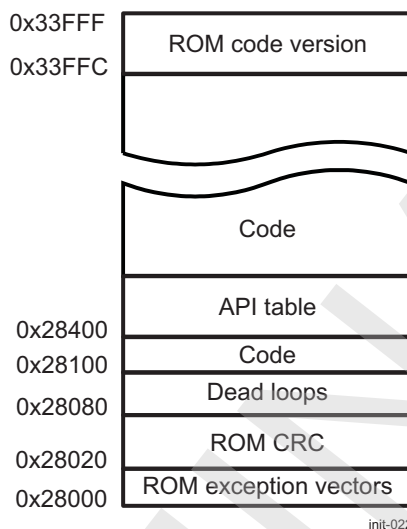

init-006

## 27.4.2 Memory Maps

### 27.4.2.1 ROM Memory Map

Figure 27-5 shows the 48-KB ROM memory map.

**Figure 27-5. ROM Memory Map**

- ROM exception vectors  
Exceptions are redirected to ROM exception vectors (see [Table 27-7](#)). The reset exception is redirected to the public ROM code startup. Other exceptions are redirected to RAM handlers by loading appropriate addresses to the PC register.

**Table 27-7. ROM Exception Vectors**

Address	Exception	Content
0x28000	Reset	Branch to the ROM code startup
0x28004	Undefined	PC = 0x4030 D004
0x28008	Software interrupt (SWI)	PC = 0x4030 D008
0x2800C	Prefetch abort	PC = 0x4030 D00C
0x28010	Data abort	PC = 0x4030 D010
0x28014	Unused	PC = 0x4030 D014
0x28018	IRQ	PC = 0x4030 D018
0x2801C	FIQ	PC = 0x4030 D01C

- ROM code cyclic redundancy check (CRC)  
The ROM code CRC is calculated as 32-bit CRC code (CRC-32-IEEE 802.3) for the address range 0x28000 - 0x33FFF. The 4-byte CRC code is stored at location 0x28020.
- Dead loops  
Dead loops are branch instructions coded in ARM™ mode. They have multiple purposes (see [Table 27-8](#)).

**Table 27-8. Dead Loops**

Address	Purpose
0x28080	Undefined exception default handler
0x28084	SWI exception default handler
0x28088	Prefetch abort exception default handler
0x2808C	Data abort exception default handler
0x28090	Unused exception default handler
0x28094	IRQ exception default handler
0x28098	FIQ exception default handler

The fixed location of these dead loops facilitates debugging and testing. The first seven dead loops are default exception handlers linked to RAM exception vectors.

Dead loops can be called directly from code, but there is also a special function called from ROM code to execute a dead loop. This function is at address 0x280C0. The function is assembly code in ARM mode, which takes the dead loop address from the R0 register. The main purpose of the function is to issue a global software reset before going to a dead loop. In addition, the function clears the global cold reset status before issuing the global software reset.

- Code

This space is used to hold code and constant data.

- API table

The purpose of this table is to allow external code access to system maintenance, utility, and device driver functions which are used for ensuring the ROM code boot functionality. These functions can be reused at run time by calling a fixed address hardcoded in this table.

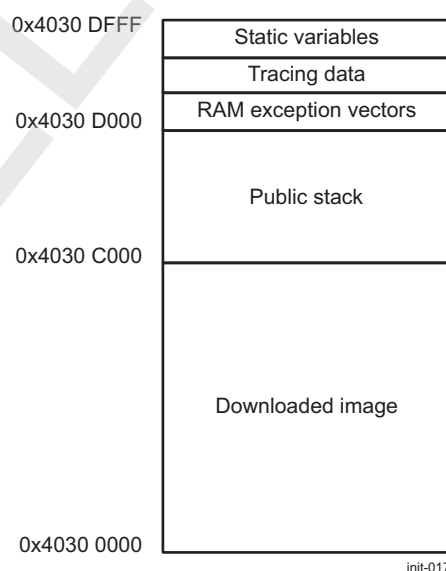

- ROM code version

The ROM code version consists of two decimal numbers: major and minor. It can be used to identify the ROM code release version burnt in a given IC (for example, useful during a debugging session). The ROM code version is a 32-bit hexadecimal value located at address 0x33FFC.

### 27.4.2.2 RAM Memory Map

The partitioning of the on-chip SRAM (L3 OCM RAM) shown in Figure 27-6 is used during the booting process. Tracing and static variables areas can also be accessed when calling API functions.

**Figure 27-6. RAM Memory Map**

- Downloaded image

This space is used by the public ROM code to store a downloaded booting image. It can be up to 48KB.

- Public stack  
This space is reserved for stack.
- RAM exception vectors  
The RAM exception vectors provide an easy way to redirect exceptions to the custom handler. [Table 27-9](#) lists the contents of the RAM space reserved for RAM vectors. The first eight addresses are ARM instructions that load the value in the subsequent eight addresses into the PC. These instructions are executed when an exception occurs because they are called from ROM exception vectors. Undefined, SWI, unused, and FIQ exceptions are redirected to a hardcoded dead loop. Prefetch abort, data abort, and IRQ exception are redirected to predefined ROM handlers. Users can redirect an exception to another handler by writing its address to the appropriate location from 0x4030 D024 to 0x4030 D03C, or by overriding the branch (load into PC) instruction between addresses from 0x4030 D004 to 0x4030 D01C.

**Table 27-9. RAM Exception Vectors**

Address	Exception	Content
0x4030 D000	Reserved	Reserved
0x4030 D004	Undefined	PC = [0x4030D024]
0x4030 D008	SWI	PC = [0x4030D028]
0x4030 D00C	Prefetch abort	PC = [0x4030D02C]
0x4030 D010	Data abort	PC = [0x4030D030]
0x4030 D014	Unused	PC = [0x4030D034]
0x4030 D018	Interrupt request (IRQ)	PC = [0x4030D038]
0x4030 D01C	Fast interrupt request (FIQ)	PC = [0x4030D03C]
0x4030 D020	Reserved	0x28090
0x4030 D024	Undefined	0x28080
0x4030 D028	SWI	0x28084
0x4030 D02C	Prefetch abort	Address of default prefetch abort handler <sup>(1)</sup>
0x4030 D030	Data abort	Address of default data abort handler <sup>(1)</sup>
0x4030 D034	Unused	0x28090
0x4030 D038	IRQ	Address of default IRQ handler
0x4030 D03C	FIQ	0x28098

<sup>(1)</sup> The default handlers for prefetch and data abort perform reads from CP15 debug registers to retrieve the reason for the abort:

- In case of prefetch abort: the IFAR register is read from CP15 and stored into R0. The IFSR register is read and stored into the R1 register. Then the ROM code jumps to the prefetch abort dead loop (20088h).
  - In case of data abort: the DFAR register is read from CP15 and stored into R0. The DFSR register is read and stored into the R1 register. Then the ROM code jumps to the data abort dead loop (2008Ch).
- Tracing data  
This area contains trace vectors reflecting the execution path of the ROM Code. The public ROM code tracing data is described in [Table 27-10](#). For more information about ROM code tracing, see [Section 27.4.9, Tracing](#).

**Table 27-10. Tracing Data**

Address	Size (Bytes)	Description
0x4030 D040	4	Current tracing vector, word 1
0x4030 D044	4	Current tracing vector, word 2
0x4030 D048	4	Current tracing vector, word 3
0x4030 D04C	4	Cold reset run tracing vector, word 1
0x4030 D050	4	Cold reset run tracing vector, word 2
0x4030 D054	4	Cold reset run tracing vector, word 3
0x4030 D058	4	Current copy of the PRM_RSTST register (reset reasons)

**Table 27-10. Tracing Data (continued)**

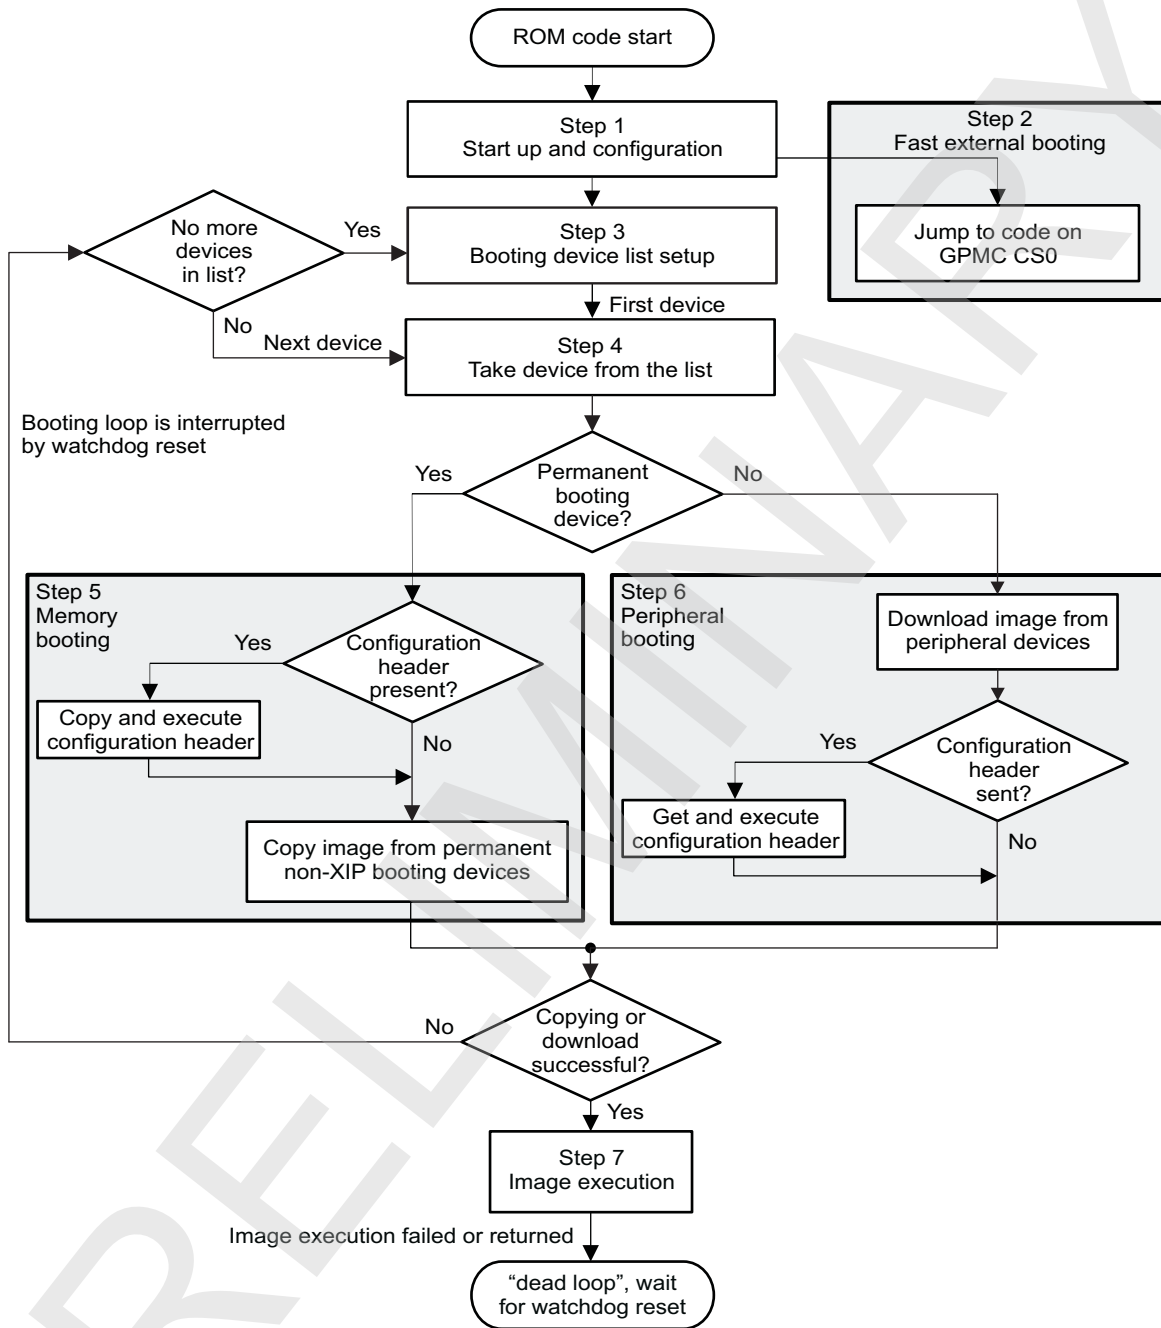

<b>Address</b>	<b>Size (Bytes)</b>	<b>Description</b>
0x4030 D05C	4	Reserved
0x4030 D060	4	Reserved
0x4030 D064	4	Reserved

- **Static variables**  
ROM code static variables used at boot time (and possibly during run time if calling the ROM API functions).

### **27.4.3 Overall Booting Sequence**

Figure 27-7 shows the ROM code flow chart.

Figure 27-7. Overall Booting Sequence

init-007

The main loop of the booting module goes through the booting device list and tries to get an image from the currently selected booting device. The ROM code performs the following steps:

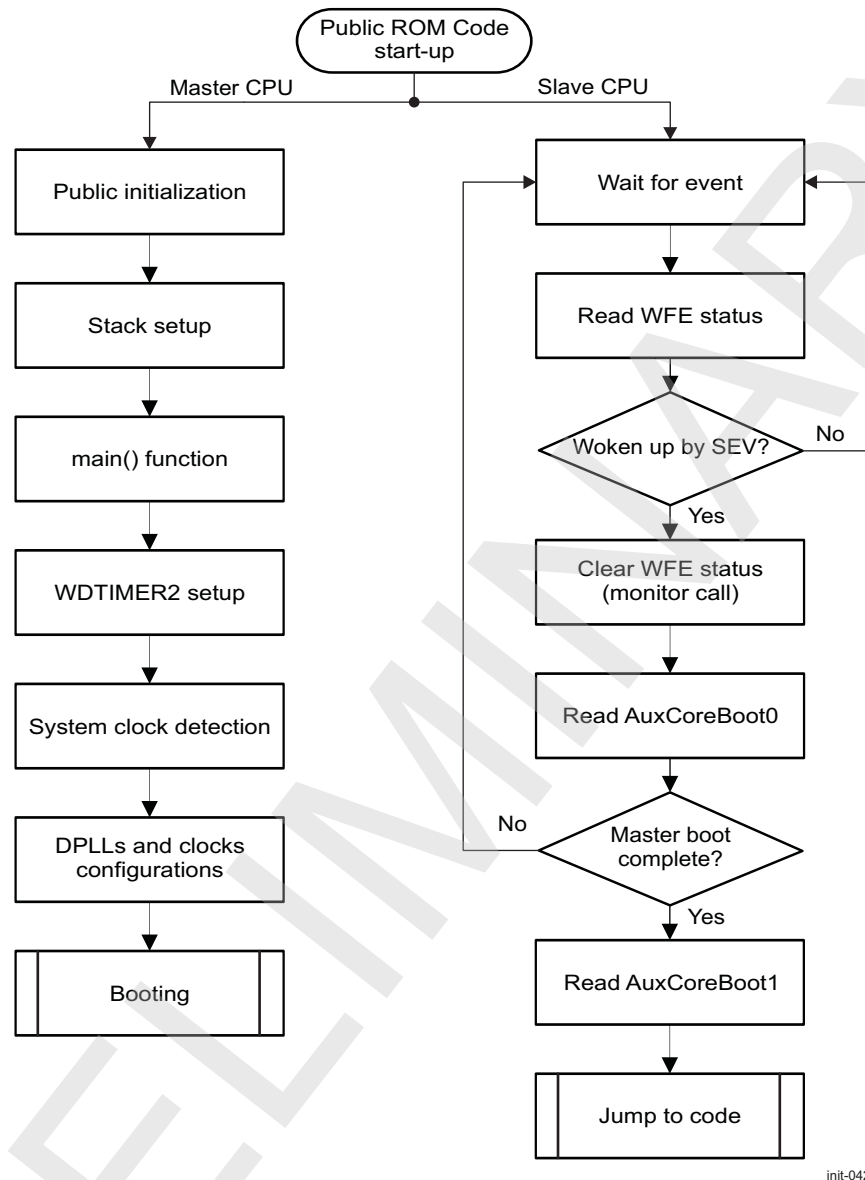

- Step 1. Basic configuration and initialization. Reading of SYSBOOT pins or software booting configuration
- Step 2. The path named fast external boot is a special low-latency boot mode. It consists of a blind jump to an external addressable memory. See [Section 27.4.6, Fast External Booting](#).
- Step 3. A booting device list is created (see [Section 27.4.4.3, Booting Device List Setup](#)). The list consists of all devices to be searched for a booting image. The list is created based on the sys\_boot pins or the software booting configuration described in [Section 27.4.4.4, Software Booting Configuration](#). The software booting configuration structure is in the SAR memory and can be written by software before executing a software reset. After a software reset, the software booting configuration has priority over the sys\_boot pin configuration.
- Step 4. The main loop of the booting procedure goes through the booting device list and tries to search for an image from the currently selected booting device. This loop is exited if a valid booting image is found and successfully executed or upon watchdog expiration. If an image is found, ROM code executes memory booting or peripheral booting, depending on the current booting device type:
  - Memory booting is executed when the booting device is XIP memory, NAND, OneNAND/Flex-OneNAND, LPDDR2-NVM, or eMMC/eSD/MMC/SD.
  - Peripheral booting is executed when the device is a UART or USB.
- Step 5. Memory booting reads data from memory type devices. Memory booting is described in detail in [Section 27.4.7, Memory Booting](#).
- Step 6. Peripheral booting downloads data from communication interfaces. Peripheral booting is described in [Section 27.4.5, Peripheral Booting](#).
- Step 7. For the GP device, the image is automatically started.

An additional feature of the booting module is the execution of the configuration header (CH). The CH configures the system for faster and more flexible booting from the selected permanent device. The CH, which is optional, is described in [Section 27.4.8.2, Configuration Header](#).

## **27.4.4 Startup and Configuration**

### **27.4.4.1 Startup**

[Figure 27-8](#) shows the ROM code start-up sequence.

**Figure 27-8. ROM Code Multiprocessor Start-Up Sequence**

init-042

The master CPU L1 instruction cache and branch prediction mechanisms are activated as part of the public boot process. The public vector base address is configured to the reset vector of ROM code (0x28000). The MMU remains switched off during boot (thus, L1 data cache is off). The master CPU performs the public-side basic initialization and stack setup (compiler auto-generated C- initialization or *scatter loading*). Next, it configures watchdog timer 2 (set to 3 minutes), performs system clock detection, and configures the system clock. Finally, it jumps to the booting routine.

No specific configuration is performed for the slave CPU, which keeps its default configuration after reset (L1 instruction and data caches off, branch prediction off, MMU off, no remap of public-vector-base address). The slave CPU is rapidly held in wait-for-event state. It stays in this state while the master CPU completes the public boot process and until jumping to the external software (for example, HLOS). At this stage, the external software can wake up the slave CPU by executing an SEV command.

Two internal memory-mapped registers are available to the OS for communicating start-up information. The AuxCoreBoot 0 and AuxCoreBoot 1 registers are located in the MPU WakeupGen domain.

- AuxCoreBoot0 is used as a status register to signal the slave CPU that it must wake up after the send event operation initiated by the master CPU.

- The AuxCoreBoot1 register contains the address location to which the slave CPU must jump after wakeup. These registers can be accessed by the master CPU (HLOS) using with the appropriate service calls (see [Section 27.5](#), *Services for HLOS Support*).

#### 27.4.4.2 Clocking Configuration

The ROM code detects the system input clock frequency. The supported frequencies are:

- 12 MHz
- 16.8 MHz
- 19.2 MHz
- 26 MHz
- 38.4 MHz

After detecting the input clock, the ROM code configures the clocks and DPLLs required for ROM code execution.

The configured DPLLs are:

- Peripheral DPLL: Set to provide 192, 128, 96, 48, 24, and 12 MHz for peripheral blocks
- Core DPLL: Set to provide L3/L4 interconnect and MPU and EMIF clocks
- MPU DPLL: Left in bypass, and the MPU internal clock is derived from the core DPLL
- USB DPLL: Locked only in case of USB peripheral booting from internal transceiver. It is left unused in other cases (for example, memory boot or peripheral boot from UART or USB ULPI) to save power.

The multipliers and dividers of the DPLLs are set to values that depend on the input clock detected.

[Table 27-11](#) summarizes the ROM code default settings for key clocks.

**Table 27-11. ROM Code Default Clock Settings**

Clock	Frequency [MHz]	Source
<b>FCORE_DPLL</b>	400	Derived from SYS_CLK
CORE_X2_CLK	200	
CORE_CLK	200	CORE_X2_CLK/1
L3_ICLK	100	CORE_CLK/2
L4_ICLK	50	L3_ICLK/2
<b>FPER_DPLL</b>	384	Derived from SYS_CLK
FUNC_192M_CLK	192	
FUNC_128M_CLK	128	
FUNC_96M_FCLK	96	
FUNC_48M_FCLK	48	
<b>FMPU_DPLL</b> (in bypass)	200	CORE_X2_CLK
MPU_DPLL_CLK	200	FMPU_DPLL/1
<b>FUSB_DPLL</b> <sup>(1)</sup>	960	Derived from SYS_CLK
INIT_960M	960	FUSB_DPLL/1
INIT_480M	480	INIT_960M/2
INIT_60M	60	INIT_480M/8

<sup>(1)</sup> Locked only in case of USB peripheral booting from internal PHY

There are three ways to change DPLLs and all related clock divider, gating, and multiplexer configurations during the boot:

- ROM code default settings, described in this paragraph. They are always applied at any reset. [Table 27-11](#)
- Software booting configuration after a software reset, described in [Section 27.4.4.4](#), *Software Booting Configuration*
- Configuration header (CH), described in [Section 27.4.8.2](#), *Configuration Header*. The CH lets users

have a known configuration (about GPMC and clock registers) after memory booting. This configuration can be blocked by the software booting configuration.

### 27.4.4.3 Booting Device List Setup

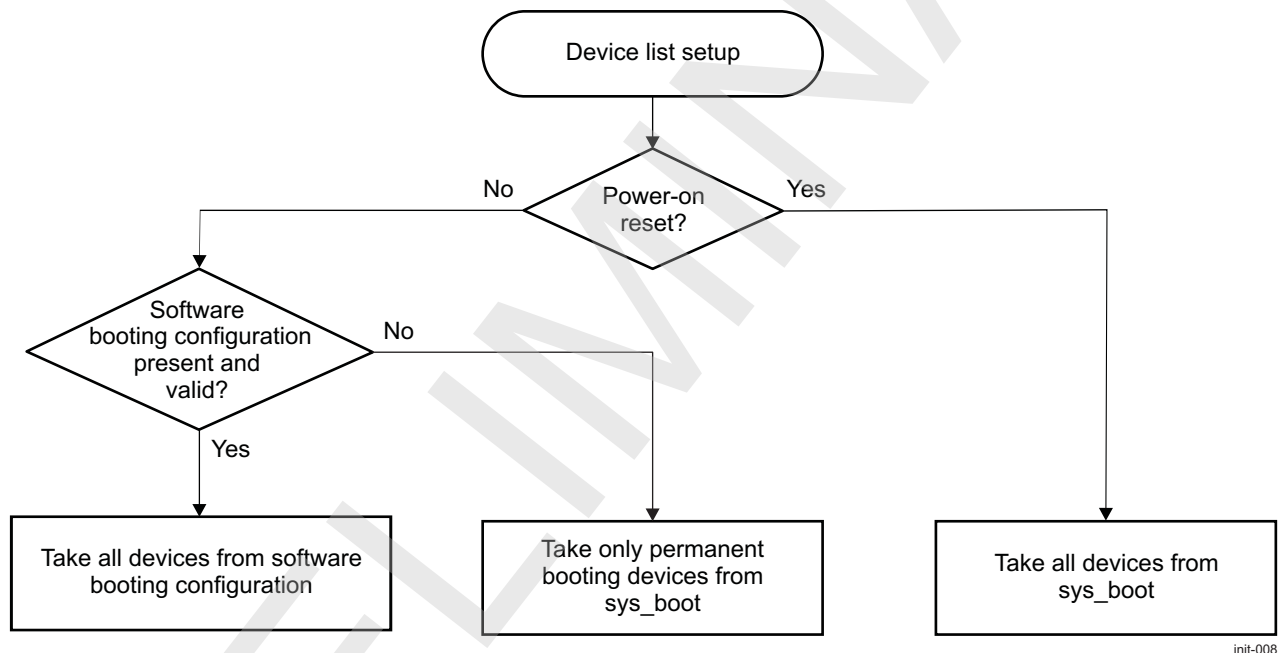

The ROM code creates a device list based on two sources:

- The software booting configuration is stored in nonvolatile RAM SAR memory.
- The sys\_boot[5:0] pins sensed in the control module are used to index the device table from which the list of devices is extracted.

Figure 27-9 shows how the ROM code sets up the device list depending on the reset source.

**NOTE:** Only permanent booting devices are put on the list when reset is not power on and devices are taken from the sys\_boot pins. Users can force peripheral booting after software reset using the software booting configuration.

**Figure 27-9. Device List Setup**

### 27.4.4.4 Software Booting Configuration

The software booting configuration is a logical structure stored in SAR RAM memory, which is not cleared after warm resets or wakeups from low-power modes.

#### 27.4.4.4.1 Public Use of SAR RAM

At system level, the OMAP4430 SAR RAM memory is divided into four banks. The public ROM code uses only the first bank, which is always public-accessible. More specifically, the software booting configuration structure must be located in the upper 1.5KB of the first bank.

The public ROM code offers some flexibility about the location of the software booting configuration structure. The PUBLIC\_SW\_BOOT\_CFG\_ADDR pointer defines the start address of the structure within the SAR RAM bank (see Table 27-12).

**Table 27-12. Public Use of SAR RAM**

Logical name	Address	Size (Bytes)	Description
PUBLIC_SW_BOOT_CFG_ADDR	0x4A326A00	4	Public software booting configuration pointer. The word value at this location is: - Reset (zero) on a cold reset. - Read on a warm reset.
CPU0_WAKEUP_NS_PA_ADDR	0x4A326A04	4	CPU0 nonsecure wake-up restoration pointer <sup>(1)</sup>
CPU1_WAKEUP_NS_PA_ADDR	0x4A326A08	4	CPU1 Nonsecure wake-up restoration pointer <sup>(1)</sup>
PUBLIC_SAR_RAM_1_FREE	0x4A326A0C	...	Recommended address for start of software booting configuration structure described in <a href="#">Section 27.4.4.4.2, Software Booting Configuration Structure</a> .

<sup>(1)</sup> This pointer is used as part of the restoration procedure from low-power modes.

As mentioned previously, the software booting configuration feature is optional. Hence, the public ROM code decides to use the feature based on the value read on a warm reset at the address pointed to by the PUBLIC\_SW\_BOOT\_CFG\_ADDR pointer. If the value matches the range 0x4A326A00 – 0x4A326FFF, the ROM code tries to extract the structure located at that address. The value pointed to by PUBLIC\_SW\_BOOT\_CFG\_ADDR is always overwritten to zero on a cold reset.

The recommended address for storing the software booting configuration structure described hereafter is defined as PUBLIC\_SAR\_RAM\_1\_FREE. It is, however, possible to locate the structure at any location within the 1.5-KB range.

It is moreover possible to use the public SAR RAM area for any other purpose, such as storing traces for HLOS use. Obviously, care must be taken not to overwrite the locations used for low-power modes and/or software booting configuration if used.

#### **27.4.4.4.2 Software Booting Configuration Structure**

**Table 27-13** describes the software booting configuration structure. It offers three levels of flexibility for redefining the ROM code defaults after a warm reset:

- Redefining the default device booting list (from ROM code defaults given by SYSBOOT pins configuration)
- Redefining the default clock settings
- Redefining timeouts linked to the peripheral booting mechanism

---

**NOTE:** The sections are provided as a linked list; therefore, the order and number of items is not relevant.

---

The ROM code searches for the next section at the location based on the size filled in the previous section. The clock configuration from software booting configuration overwrites the CH settings.

**Table 27-13. Software Booting Configuration Structure**

Field	Size (Bytes)	Description

Padding	2	

## 27.4.5 Peripheral Booting

### 27.4.5.1 Description

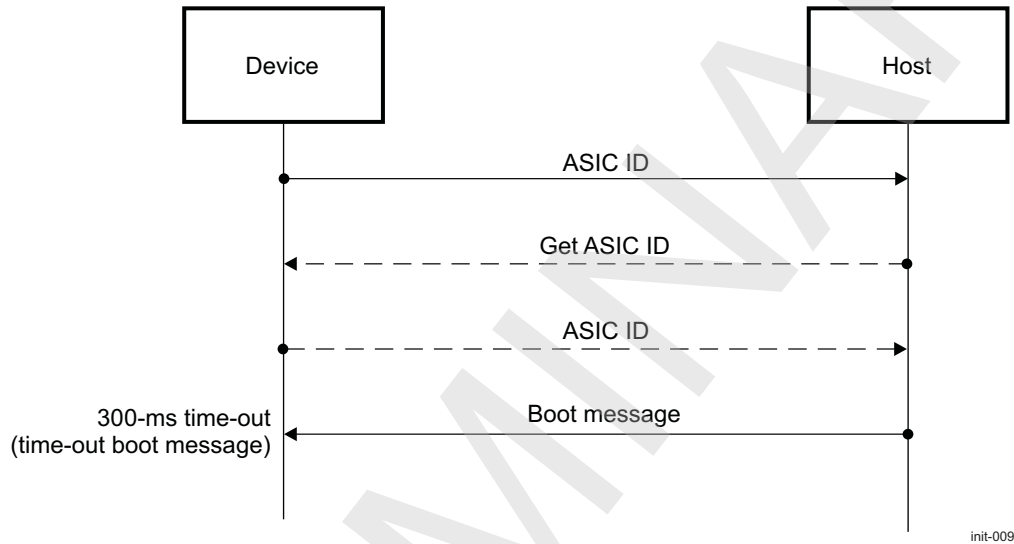

The ROM code can boot from two different peripherals:

- USB: High/full speed USB from internal or external transceiver
- UART3: 115.2 Kbps, 8 bits, even parity, 1 stop-bit

The purpose of booting from a peripheral is to download a flash loader code from an external host. This booting method is used primarily for programming flash memories connected to the OMAP device (for example, in the case of initial flashing, firmware update or servicing). The overall peripheral booting procedure is shown in [Figure 27-12](#). It consists of a synchronization phase (handshake between host and OMAP device) and a transfer phase. The synchronization phase is similar for UART and USB boots. Both transfer phases use the same procedure.

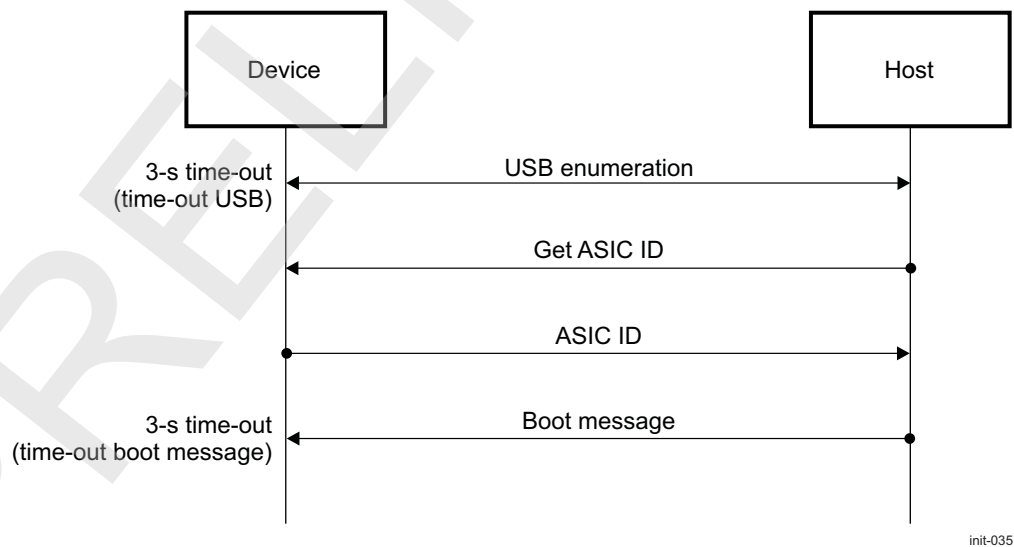

When booting from the UART, the ROM code first initializes the UART3 interface. Then the ROM code sends an ASIC ID block of data. From there, it expects to receive a boot message from the host within 300 ms, by default. [Figure 27-10](#) shows this procedure.

**Figure 27-10. Synchronization Phase for UART**

[Figure 27-11](#) shows the procedure when booting from the USB.

**Figure 27-11. Synchronization Phase for USB**

During the synchronization phase ([Figure 27-10](#) and [Figure 27-11](#)), the OMAP device can provide a small packet of data called the ASIC ID (described in [Table 27-14](#)). It is a simple structure that contains different kinds of information, such as ROM version, checksums, and ID.

The default time-outs involved during the synchronization phase can be redefined after a warm reset by means of the software booting configuration (described in [Section 27.4.4.4, Software Booting Configuration](#)). The host can decide the desired operation by providing a booting message ([Table 27-18](#)). This message can be: Get ASIC ID, peripheral boot, change device, or next device. If the OMAP device receives the Get ASIC ID boot message, it sends back the ASIC ID contents.

If the change device or next device message is received, the ROM code stops the current peripheral booting procedure and returns to the main booting, which decides about the next booting device according to the boot message received.

If the peripheral boot message is received without a time-out, the OMAP device is entering the transfer phase. From there, the flash loader image size (as a 32-bit word) and the flash loader image itself are expected to be received. The ROM code waits up to 1 minute for completion of image size reception, and up to 1 more minute to download the image. If the download procedure does not complete before this time, the peripheral booting returns with a TIMEOUT status. ROM code continues to examine the devices included in the booting device list. If the download procedure passes, the peripheral booting returns with a SUCCESS status and the image can be executed.

The USB or UART connection is left open at the end of the transfer phase and once exiting the ROM code for the initial software to take over. It means the initial software can “reuse” the currently established connection. In case of USB, the endpoints can be reused as such, without closing the connection and performing a full enumeration again.

**Table 27-14. ASIC ID Structure**

ASIC ID Item	Size (Bytes)	Description
Items	1	Number of subblocks
ID subblock	7	Device identification information
Reserved subblock	4	This subblock is transmitted, but does not contain useful information in case of GP-device.
Reserved subblock	23	This subblock is transmitted, but does not contain useful information in case of GP-device.
Reserved subblock	35	This subblock is transmitted, but does not contain useful information in case of GP-device.
Checksum subblock	11	CRC (4 bytes)

**Table 27-15. Items**

Offset	Size (Bytes)	Description
0x00	1	0x05: Number of subblocks USB 0x04: Number of subblocks UART <sup>(1)</sup>

<sup>(1)</sup> The checksum subblock is not transmitted over the UART.

**Table 27-16. ID Subblock**

Offset	Size (Bytes)	Description
0x01	1	0x01: Subblock ID
0x02	1	0x05: Subblock size
0x03	1	0x01: Fixed value
0x04	2	0x44, 0x30: OMAP4430 device
0x06	1	0x07: CH enabled (read from eFuse) 0x17: CH disabled (read from eFuse)
0x07	1	ROM revision

Offset	Size (Bytes)	Description
0x48	1	0x01: Fixed value
0x49	4	ROM CRC
0x4D	4	0x00000000: For GP device

**Table 27-18. Booting Messages**

Message Name	Value	Description
Peripheral boot	0xF0030002	Continue peripheral booting.
Get ASIC ID	0xF0030003	ASIC ID request. The Get ASIC ID request message is optional. If received, the ROM code sends its ASIC ID data to the host in return. The host can issue the Get ASIC ID message multiple times if required. The structure of the ASIC ID is described in <a href="#">Table 27-14</a> .
Change device	0xF003xx06	Skip current peripheral booting and continue booting from device type indicated by xx: 0x00: Void, no device 0x01: XIP memory 0x02: XIPWAIT memory (wait-signal monitoring on) 0x03: NAND 0x04: OneNAND 0x05: MMC1 0x06: MMC2(1) 0x07: MMC2(2) 0x08: EMIF 0x43: UART 3 0x45: USB (internal transceiver) 0x46: USB-ULPI Others: Reserved
Next device	0xFFFFFFFF	Skip current device and move to the next device on the device list.
Memory booting	Others	Skip current peripheral booting and move to the first device for memory booting.

Figure 27-12 shows the peripheral booting procedure.

Figure 27-12. Peripheral Booting Procedure

init-010

### 27.4.5.2 UART

The ROM code supports booting from a UART interface with the following characteristics:

- UART interface 3
- Communication parameters set to 115.2 Kbps, 8 bits, even parity, 1 stop-bit
- Two-pin interface: RX/TX
- The boot message default time-out is 300 ms (time-out boot message)

### 27.4.5.3 USB

The ROM code supports booting from a USB interface with the following characteristics:

- HSUSBOTG interface (USBA0)
- OMAP integrated transceiver (USBPHY) or external transceiver through the ULPI
- Enumeration default time-out is 3 s (timeout USB)
- The boot message default time-out is 3 s (timeout boot message).

---

**NOTE:** Even though using an OTG capable hardware, the ROM code does not handle any OTG-specific features.

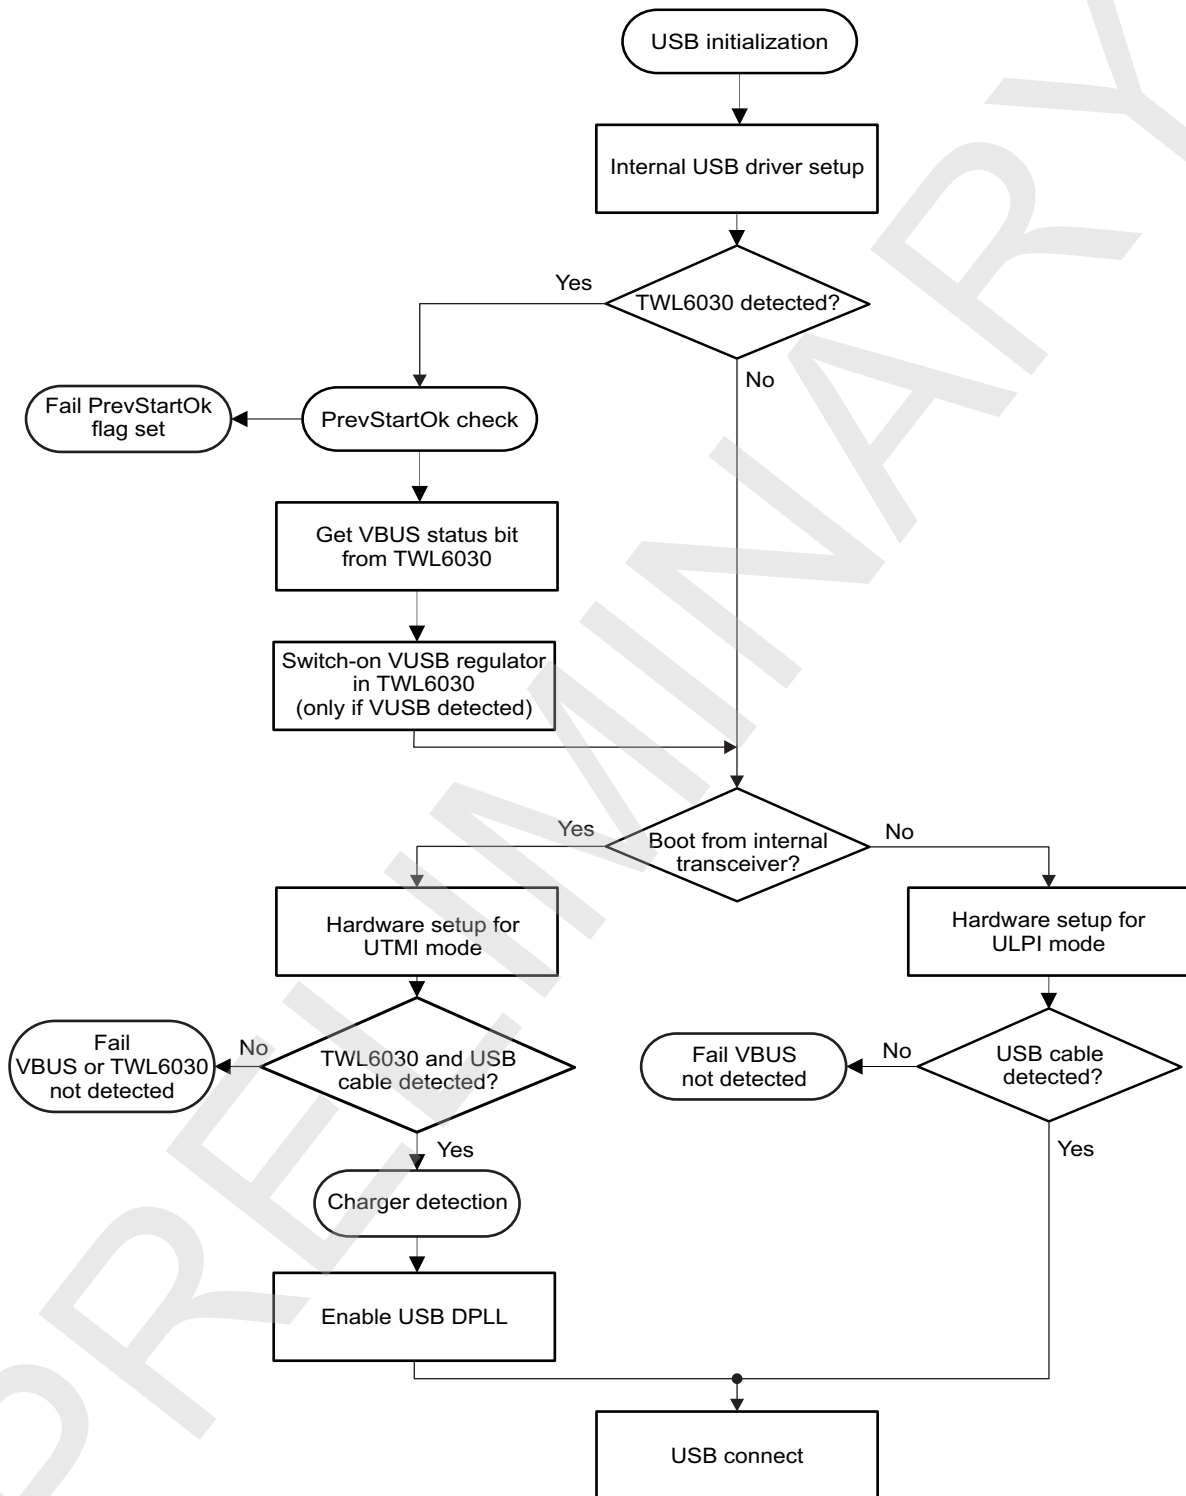

---

#### 27.4.5.3.1 Overview

[Figure 27-13](#) shows the USB initialization procedure.

Figure 27-13. USB Initialization Procedure

init-037

After internal USB module driver setup, the TWL6030 power IC is checked for presence. If found, the following actions are performed using I<sup>2</sup>C transactions through the I2C1 interface:

- PrevStartOk status flag check, as described in [Section 27.4.5.3.2](#).
- Get the VBUS status reflecting presence (or not) of the USB cable
- If VBUS was detected, then the VUSB regulator is enabled to power the internal OMAP transceiver.

In case of boot from external transceiver in accordance with the chosen SYSBOOT configuration:

- The HSUSBOTG hardware and PRCM clocks are configured for ULPI mode.
- The ROM code continues with the USB procedure only if the USB cable is detected (that is, VBUS is detected at external transceiver level and communicated as such through the ULPI traffic). If not, the initialization procedure is aborted.

---

**NOTE:** The OMAP USB DPLL is not set up in case of ULPI mode, for which the 60-MHz clock is driven by the external transceiver.

---

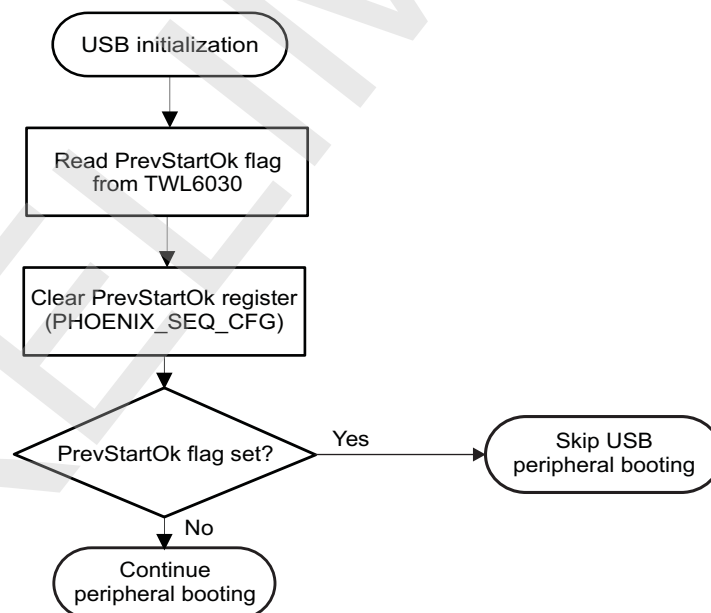

In case of boot from internal transceiver in accordance with the chosen SYSBOOT configuration:

- The USBOTGHS hardware and PRCM clocks are configured for UTMI mode and internal PHY clocks are enabled.
- The ROM code continues with the USB procedure only if TWL6030 (or emulator) is detected and the USB cable is detected (that is, VBUS is detected at the TWL6030 level and read as such with a register read through I<sup>2</sup>C). If not, the initialization procedure is aborted.
- The ROM code proceeds with charger detection, as described in [Section 27.4.5.3.2](#).
- It enables the USB DPLL for feeding the appropriate 60-MHz clock needed by the internal transceiver.

### 27.4.5.3.2 PrevStartOk Status Flag Check

The ROM code supports a mechanism for avoiding the boot time spent because of the enumeration time-out (default 3 s) in case the USB cable is attached and the USB option is present in the selected boot list but is not intended to initiate a peripheral booting procedure (for example, firmware update or flashing). This mechanism is jointly handled with the support of the TWL6030 device (not supported if TWL6030 is not detected). This mechanism is supported only for USB and not UART (see [Figure 27-14, PrevStartOk Mechanism](#)).

**Figure 27-14. PrevStartOk Mechanism**

init-038

The ROM code first checks the value of a register in the TWL6030 RTC domain (hence, retained by the backup battery when the platform is switched off) by means of an I<sup>2</sup>C read access. If the PrevStartOk bit in this register is set, the USB peripheral booting is simply skipped. In any case, the bit is reset (zeroed) by

the ROM code, which means that the USB peripheral boot is re-enabled on the next cold reset (or warm reset if suitable software booting configuration is present). The initial software of the user must set this bit again by an I<sup>2</sup>C write access to disable USB peripheral booting on a subsequent reset. For more information about the accesses made towards PrevStartOk in the PHOENIX\_SEQ\_CFG register, see TWL6030 documentation.

### 27.4.5.3.3 Charger Detection

The ROM code proceeds with charger detection as part of the USB peripheral booting procedure and in compliance with the *Battery Charging Specification Revision 1.1*. It uses the specific charger detection hardware embedded in the OMAP device. Figure 27-15 shows the high-level procedure.

Figure 27-15. Charger Detection

The hardware charger detection mechanism should end up within the 500-ms time-out. The main goal of such detection is to gate the charger circuitry in TWL6030 in case a charger is not detected and a suspend event is detected on the OMAP side, for which the power consumption must be reduced.

### 27.4.5.3.4 SUSPEND and RESUME Handling

The SUSPEND event is detected by the HSUSBOTG module when activity on the bus stops for at least 3 ms. During peripheral booting time, a SUSPEND event is detected by the ROM code and processed by initiating a write into the TWL6030 to gate the charging circuitry. The ROM code releases the TWL6030 charger circuitry upon getting a RESUME event. During run time, SUSPEND and RESUME interrupts can be routed to the initial software for defining custom handling.

### 27.4.5.3.5 USB Driver Descriptors

USB devices report their attributes using descriptors. A descriptor is a data structure with a defined format. Each descriptor begins with a byte-wide field that contains the total number of bytes in the descriptor followed by a byte-wide field that identifies the descriptor type. Using descriptors allows concise storage of the attributes of individual configurations so that each configuration can reuse descriptors or portions of descriptors from other configurations that have the same characteristics. Where appropriate, descriptors contain references to string descriptors. String descriptors contain displayable, human-readable description information. These descriptor details can be used for tool development or debugging:

- Device descriptor

A device descriptor contains general information about a USB device, including global information that applies to the device and all device configurations. A USB device has only one device descriptor. A device-qualifier descriptor is required because the ROM code uses the HS feature of the USB core. [Table 27-19](#) lists the device descriptors.

**Table 27-19. Device Descriptor**

Field	Value	Description
bLength	0x12	Size of this descriptor in bytes
bDescriptorType	0x01	Device descriptor type
bcdUSB	0x0210	USB specification release number in binary coded decimal (BCD) format
bDeviceClass	Vendor-specific (0xFF)	Class code
bDeviceSubClass	Vendor-specific (0xFF)	Subclass code
bDeviceProtocol	Vendor-specific (0xFF)	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
idVendor	0x0451	Vendor ID (Texas Instruments), TI default value
idProduct	0xD00F	Product ID (OMAP4430), TI default value
bcdDevice	0x0000	Device release number
iManufacturer	See <a href="#">Section 27.4.5.3.6</a> .	Index of string descriptor describing manufacturer
iProduct	See <a href="#">Section 27.4.5.3.6</a> .	Index of string descriptor describing product
iSerialNumber	See <a href="#">Section 27.4.5.3.6</a> .	Index of string descriptor describing device serial number
bNumConfigurations	0x01	Number of possible configurations

- Device-qualifier descriptor

The device-qualifier descriptor contains information about a HS-capable device that changes if the device operates at its other speed. This descriptor is retrieved by the host using the GetDescriptor() request (standard device request). [Table 27-20](#) describes a device-qualifier descriptor.

**Table 27-20. Device-Qualifier Descriptor**

Field	Value	Description
bLength	0x0a	Size of this descriptor in bytes
bDescriptorType	0x06	Device-qualifier descriptor type
bcdUSB	0x0210	USB specification release number in BCD
bDeviceClass	0xFF	Class code
bDeviceSubClass	0xFF	Subclass code
bDeviceProtocol	0xFF	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
bNumConfigurations	0x01	Number of possible configurations
bReserved	0x00	Reserved for future use

- Configuration descriptor

This descriptor gives information about a specific device configuration. It describes the number of interfaces supported by the configuration (see [Table 27-21](#)).

**Table 27-21. Configuration Descriptor**

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x02	Configuration descriptor type
wTotalLength	–	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xC0	Power setting and remote wakeup

**Table 27-21. Configuration Descriptor (continued)**

Field	Value	Description
bMaxPower	0x32	Maximum power consumption of the USB device

- Other speed configuration descriptor  
This descriptor describes the configuration of a HS-capable device if it operates at its other possible speed (see [Table 27-22](#)).

**Table 27-22. Other Speed Configuration Descriptor**

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x07	Other speed configuration descriptor type
wTotalLength	–	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xC0	Power setting and remote wakeup
bMaxPower	0x32	Maximum power consumption of the USB device

- Interface descriptor  
This descriptor describes a specific interface in a configuration (see [Table 27-23](#)).

**Table 27-23. Interface Descriptor**

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x04	Interface descriptor type
bInterfaceNumber	0x00	Number of this descriptor
bAlternateSetting	0x00	Value to select the alternate setting
bNumEndpoints	0x02	Number of endpoints used for this interface
bInterfaceClass	0xFF	Class code
bInterfaceSubClass	0xFF	Subclass code
bInterfaceProtocol	0xFF	Protocol code
iInterface	Index	Index of string descriptor describing this interface

- Endpoint descriptor  
Each endpoint used for an interface has its own descriptor. This descriptor contains information required by the host to determine the bandwidth requirements of each endpoint. This descriptor is returned as part of the GetDescriptor(Configuration) request. (see [Table 27-24](#) and [Table 27-25](#)).

**Table 27-24. BULK IN Endpoint Descriptor**

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x81 (1 IN)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See <sup>(1)</sup> .	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

<sup>(1)</sup> The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

**Table 27-25. BULK OUT Endpoint Descriptor**

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x01 (1 OUT)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See <sup>(1)</sup> .	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

<sup>(1)</sup> The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

- String descriptors

String descriptors use UNICODE encoding. The strings in a USB device can support multiple languages. When requesting a string descriptor, the requester specifies the desired language using a 16-bit language ID (LANGID) defined by the USB interface. String index 0 for all languages returns a string descriptor that contains an array of 2-byte LANGID codes supported by the device.

For the description of the different string descriptors, see:

- The language ID string descriptor ([Table 27-26](#))
- The manufacturer ID string descriptor ([Table 27-27](#))
- The product ID string descriptor ([Table 27-28](#))
- The configuration string descriptor ([Table 27-29](#))
- The interface string descriptor ([Table 27-30](#))

**Table 27-26. Language ID String Descriptor**

Field	Value	Description
bLength	0x04	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
wLangId	0x0409 (US English)	Language ID code

**Table 27-27. Manufacturer ID String Descriptor**

Field	Value	Description
bLength	0x24	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	Texas Instruments	Manufacturer string

**Table 27-28. Product ID String Descriptor**

Field	Value	Description
bLength	0x12	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	OMAP4430	Product string

**Table 27-29. Configuration String Descriptor**

Field	Value	Description
bLength	0x08	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	psc	Configuration string

**Table 27-30. Interface String Descriptor**

Field	Value	Description
bLength	0x08	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type

**Table 27-30. Interface String Descriptor (continued)**

Field	Value	Description
bString	pbi	Interface string

**27.4.5.3.6 USB Customized Descriptors**

There are two parameters in USB descriptors that customers can define after the chip is created: vendor ID (VID) and product ID (PID). The ROM code uses dedicated eFuses that hold VID and PID values. Other parameters can also be changed based on the VID value. The ROM code has an encoded set of parameters for customers who have defined their requirements before the ROM code has been done. [Table 27-31](#) lists the parameters that depend on the VID value.

**Table 27-31. Customized Descriptor Parameters**

Parameter	Size (Bytes)	Default Values (From eFuses)	TI Default Values (From ROM)
Device ID code	2	0x0000	0x0000
Device class	1	0xFF	0xFF
Device subclass	1	0xFF	0xFF
Device protocol	1	0xFF	0xFF
Manufacturer	String	N/A	Texas Instruments
Product	String	OMAP4430	OMAP4430
Serial number	String	See <sup>(1)</sup>	See <sup>(1)</sup>

<sup>(1)</sup> The standard device descriptor indicates that the device has no serial number.

[Figure 27-16](#) shows an additional customer parameter selection method. It is based on the VID burned in the USB eFuses.

**Figure 27-16. Customer USB Descriptor Selection**

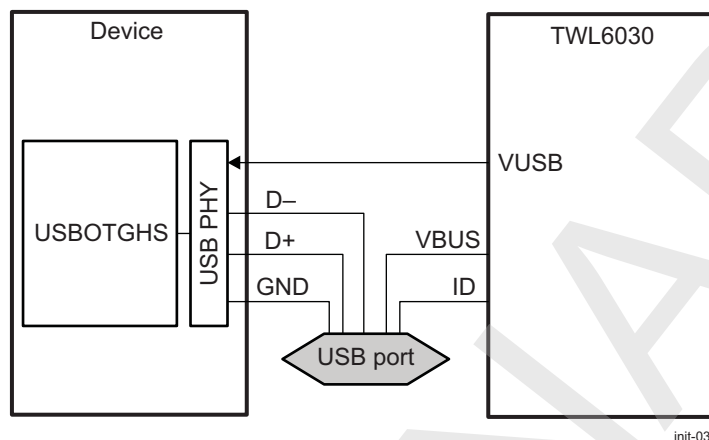

init-011

### 27.4.5.3.7 System Interconnection – Integrated Transceiver

When SYSBOOT selects the embedded PHY, the USB power/data path can be described as shown in Figure 27-17.

**Figure 27-17. USB System Using Internal Transceiver**

### 27.4.5.3.8 System Interconnection - External Transceiver

The USBOTGHS module uses the ultralow-pin-count interface (ULPI) to interconnect with an external USB transceiver. In this case, the ROM code does not interact with the transceiver. Thus, users must ensure that the transceiver power supply and clock are present and the transceiver is out of reset.

### 27.4.5.3.9 USB Driver Functionality

- Transactions supported:
  - Control transactions: Used for standard device requests
  - Bulk transactions: Used for data transfer in the image downloading stage. The ASIC ID is sent to the Bulk IN endpoint and the image is transferred from the host over the Bulk OUT endpoint.

The OMAP USB device first attaches to the host as an FS device. In the reset mechanism, the USB core requests HS operation. If the HS negotiation in the reset phase is successful, further transactions are at HS; otherwise, they are at FS. After reset, the USB driver checks for the speed of the device, whether it is FS or HS. Depending on the speed configured by the host, the standard USB device requests are answered with the corresponding descriptors.

- Standard device request restrictions:
 

Some standard device requests are not supported by the driver because the USB driver is dedicated for use by the ROM code for peripheral booting. Table 27-32 lists the standard device requests supported by the driver.

**Table 27-32. Standard Device Requests Supported**

Request	Description	Support
CLEAR_FEATURE	Sets/clears a specific feature	Supported only for ENDPOINT_HALT feature
GET_CONFIGURATION	Returns the current device configuration value	Yes
GET_DESCRIPTOR	Returns the specified descriptor	Yes
GET_INTERFACE	Returns the selected alternate setting for the specified interface	Yes
GET_STATUS	Returns the status for the specified recipient	Yes
SET_ADDRESS	Sets the device address	Yes
SET_CONFIGURATION	Sets the device configuration	Yes
SET_DESCRIPTOR	Updates existing descriptors or adds new descriptors	Runtime updating of descriptors is not supported.
SET_FEATURE	Sets or enables a specific feature	Supported only for ENDPOINT_HALT feature

**Table 27-32. Standard Device Requests Supported (continued)**

<b>Request</b>	<b>Description</b>	<b>Support</b>
SET_INTERFACE	Selects an alternate setting in an interface	Runtime setting of alternate features is not supported.
SYNCH_FRAME	Sets and reports an endpoint synchronization frame	No, because isochronous transfers are not used

## **27.4.6 Fast External Booting**

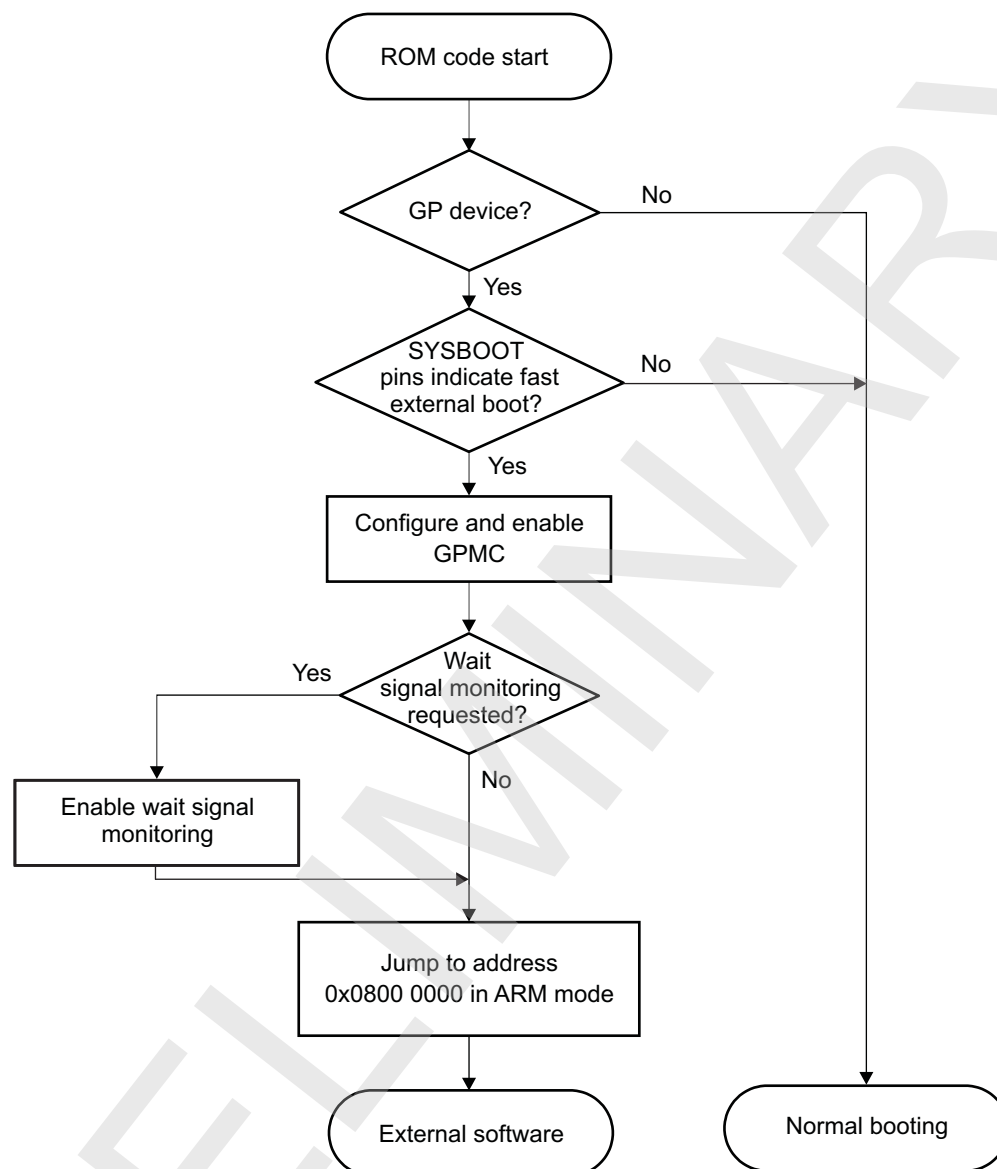

### **27.4.6.1 Overview**

The fast external boot is a special memory booting mode, possible only on GP devices. It consists of a blind jump to a code in an external XIP memory device connected to GPMC CS0. Fast external booting is set up by means of the SYSBOOT configuration pins and lets customers create their own booting code.

The jump is performed with minimum on-chip ROM code execution.

### **27.4.6.2 Fast External Booting Procedure**

[Figure 27-18](#) shows the fast external boot procedure. The code is at the beginning and is written in assembly. The code does not use any RAM and is designed for fast execution.

**Figure 27-18. Fast External Boot Procedure**

init-013

## 27.4.7 Memory Booting

### 27.4.7.1 Overview

The memory booting process starts an external code in memory devices. Only memory type of booting devices can be used by ROM code as permanent booting devices (that is, devices examined after both cold (POR) and warm resets). Temporary booting devices are examined only after cold resets. The supported permanent booting devices are:

- NOR flash devices
- NAND flash devices
- OneNAND/Flex-OneNAND devices
- eMMC/eSD embedded flash memories
- SD/MMC flash cards
- LPDDR2-NVM

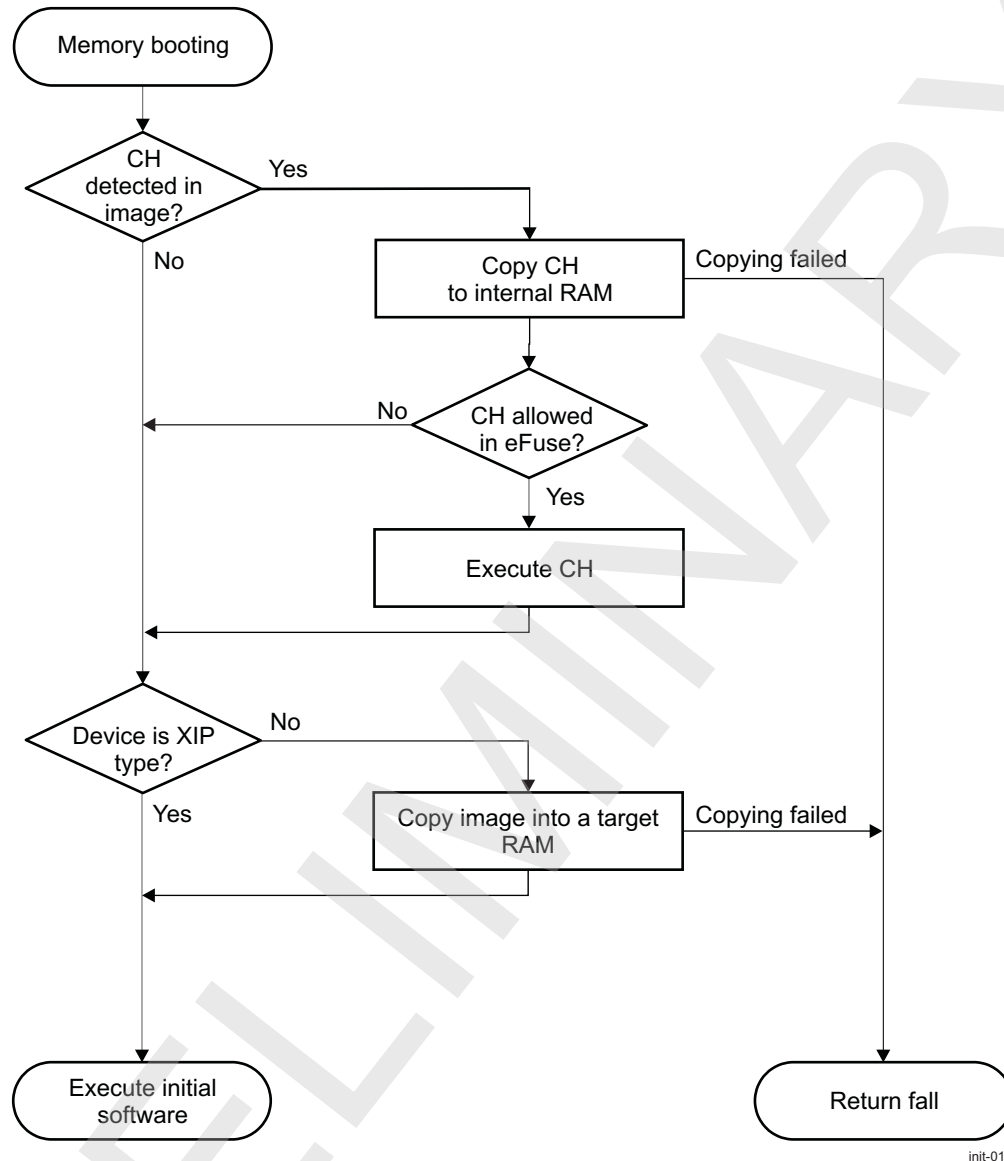

Two main groups of permanent booting devices are distinguished by code shadowing. Code shadowing means copying code from a nondirectly addressable device (non-XIP) to RAM, where the code can be executed. Directly addressable devices are XIP devices.

Figure 27-19 shows the general memory booting procedure common to all types of devices. First, CH is copied to internal RAM. It is copied even for XIP devices, because the OMAP device can temporarily lose a connection with XIP memory during CH execution. The second step is to shadow the image, if the device is not XIP. The last step is image execution and any return from image results in a dead loop.

If CH copying or shadowing fails, memory booting returns to the main booting procedure, which selects the next device for booting.

During the first read sector (512 bytes) call, sectors are copied to a temporary RAM buffer. Once the image is found and the destination address is known, the content of the temporary buffer is moved to the target RAM location so it is required to reread the first image sector. On a GP device, the GP header is discarded; therefore, only executable code is located in RAM, with the first executable instruction located at the destination address.

eMMC/eSD embedded memories, MMC/SD cards, NAND, and OneNAND/Flex-OneNAND devices can hold up to four copies of the booting image. Therefore, the ROM code searches for one valid image out of the four, if present, by walking over the first blocks of mass storage space. Other XIP devices (NOR) use only one copy of the booting image.

**Figure 27-19. Memory Booting Procedure**

### 27.4.7.2 Non-XIP Memory

Figure 27-20 shows the procedure used when memory booting runs with non-XIP devices. The grayed procedures are specific to each device. NAND and OneNAND/Flex-OneNAND devices use up to four copies of the image in the first four physical blocks. Therefore, the ROM code searches for the image in the first four physical blocks of these devices. Other devices use only one copy of the image and the block loop runs only once.

During image shadowing on a GP device, the CH is expected to be in a separate sector before the initial software.

Figure 27-20. Image Shadowing on GP Device

init-015

Table 27-33 summarizes the number of blocks and sectors searched during memory booting from devices requiring image shadowing. A sector is assumed to be 512 bytes long. NANDs and OneNAND/Flex-OneNAND are organized with blocks, which are erasable units. MMC/SD/eMMC/eSD + FAT12/16/32 booting consists of reading a file.

Table 27-33. Blocks and Sectors Searched on Non-XIP Memories

Memory	Maximum Number of Checked Blocks	Number of Sectors Searched
NAND	First 4	Number of sectors in a block <sup>(1)</sup>
OneNAND/Flex-OneNAND	First 4	8
eMMC/eSD raw	First 4	1
MMC/SD raw	First 4	1
MMC/SD/eMMC/eSD + FAT12/16/32	1 File	

<sup>(1)</sup> Depends on NAND geometry

For more information about the GPMC module, see Section 15.4, GPMC Overview.

The following sections describe the supported device types.

### 27.4.7.3 XIP Memory

The ROM code can boot directly from XIP devices, such as NOR flash memories, that have the following characteristics:

- The GPMC is the communication interface.
- Memories up to 1 Gb (128MB) can be connected.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- The GPMC clock is 50 MHz.
- The device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc\_wait0 is monitored according to the sys\_boot configuration pins.

Depending on the SYSBOOT option, the GPMC can be configured to use the wait signal connected to the gpmc\_wait0 pin. Wait pin polarity is set to stall accessing memory when gpmc\_wait0 is low. Wait-signal monitoring is used with memories that require a long time for initialization after reset, or that must pause while reading data.

For an XIP memory booting, no user intervention is required; the following debugging steps are described. Only CH, which is not mandatory, lets users change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device.

Bootting from an XIP device consists of the following steps:

1. Configure the GPMC for XIP device access.
2. Verify that the CH is present at address 0x0800 0000. If it is, copy the entire sector (512 bytes) to internal RAM and execute CH.
3. Set the image location:
  - 0x0800 0000 if the CH is not found
  - 0x0800 0200 if the CH is found
4. Verify that a bootable image is at the image location.
5. Execute the image if it is found.
6. If the image is not found, return from XIP booting to the main booting loop.

#### 27.4.7.3.1 GPMC Initialization

Table 27-34 lists the timing settings of the GPMC when set for XIP and other address-data accessible devices, such as OneNAND/Flex-OneNAND. Table 27-34 is included for debug information.

**Table 27-34. XIP Timing Parameters**

Parameter	Value [Clock Cycles] (1)	Register Initialization (where i = 0–7)	Reset Value
Write cycle period	17	The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x11.	0x11
Read cycle period	17	The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x11.	0x11
CS low time	1	The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x1.	0x1
CS high time	16	The GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field is set to 0x10.	0x10
ADV low time	1	The GPMC_CONFIG3_i[3:0] ADVONTIME bit field is set to 0x1.	0x1
ADV high time	2	The GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field is set to 0x2.	0x2
OE low time	3	The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x3.	0x6
OE high time	16	The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field is set to 0x10.	0x10
WE low time	3	The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3.	0x05
WE high time	15	The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field is set to 0xF.	0x10
Data latch time	15	The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xF.	0x0F

(1) The one clock cycle is 20 ns, which corresponds to 50-MHz frequency.

There is no specific identification routine executed before booting from an XIP device.

#### 27.4.7.4 NAND

NAND flash memory is not an XIP device; it requires shadowing before the code can be executed. ROM code support for the NAND flash devices has the following characteristics:

- The GPMC is the communication interface.
- Device from 512 Mbit (64MB)
- x8 and x16 bus width
- Support for large page size (2048 bytes + 64 spare bytes) or very large page size 4096 bytes + 128/218 spare bytes)
- Chip enable (CE) don't care devices only
- Single-level cell (SLC) and multilevel cell (MLC) devices
- Device identification based on ONFI or ROM table
- ECC correction: 8 bits/sector for most devices (16 bits/sector for devices with large spare area)
- GPMC timings are adjusted for NAND access.
- The GPMC clock is 50 MHz.
- The device is connected to CS0.
- The wait pin signal gpmc\_wait0 is connected to the NAND BUSY output.
- Four physical blocks are searched for an image. Block size depends on the device.

For NAND memory booting, no user intervention is needed; the information in the following subsections is included for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

#### 27.4.7.4.1 Initialization and NAND Detection

The initialization routine for NAND consists of three parts: GPMC initialization, device detection with parameter determination, and bad block detection.

- GPMC initialization

The GPMC interface is configured so that it can access NAND. Because NAND memories do not need the address bus, it is released. The data bus width is initially set to 8 bits. If necessary, it is changed to 16 bits after the device parameters are determined. [Table 27-35](#) shows the GPMC configuration used during NAND boot. [Table 27-35](#) is included for debug information.

**Table 27-35. NAND Timing Parameters**

Parameter	Value (Clock Cycles)	Register Initialization (where i = 0–7)	Reset Value
Write cycle time	20	GPMC_CONFIG5_i[12:8] WRCYCLETIME = 0x14	0x11
Read cycle time	20	GPMC_CONFIG5_i[4:0] RDCYCLETIME = 0x14	0x11
CS low time	0	GPMC_CONFIG2_i[3:0] CSONTIME = 0x0	0x1
CS low to OE low time	5	GPMC_CONFIG4_i[3:0] OEONTIME = 0x5	0x6
CS low to OE high time	16	GPMC_CONFIG4_i[12:8] OEOFFTIME = 0x10	0x10
CS low to WE low time	1	GPMC_CONFIG4_i[19:16] WEONTIME = 0x1	0x5
CS low to WE high time	15	GPMC_CONFIG4_i[28:24] WEOFFTIME = 0xF	0x10
CS low to data latch time	14	GPMC_CONFIG5_i[20:16] RDACCESSTIME = 0xE	0xF

- Device detection and parameters

The ROM code first performs an initial wait for device auto initialization (with 250-ms time-out) with polling of the ready information. Then, it needs to identify the NAND type connected to the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND device is reset (command FFh) and its status is polled until ready for operation (with 100-ms time-out). The ONFI Read ID (command 90h/address 20h) is sent to the NAND device. If it replies with the ONFI signature (4 bytes) then a Read parameters page (command ECh) is sent. The information provided in [Table 27-36](#) is then extracted: page size, spare area size, number of pages per block, and the addressing mode. The remaining data bytes from the parameter page stream are simply ignored.

**Table 27-36. ONFI Parameters Page Description**

Offset	Description	Size (Bytes)
6	Features supported	2
80	Number of data bytes per page	4
84	Number of spare bytes per page	2
92	Number of pages per block	4
101	Number of address cycles	1

If the ONFI Read ID command fails (it will be the case with any device not supporting ONFI) then the device is reset again with polling for device to be ready (with 100ms timeout). Then, the standard Read ID (command 90h / address 00h) is sent. If the Device ID (2nd byte of the ID byte stream) is recognized as being a supported device then the device parameters are extracted from an internal ROM Code table. [Table 27-37](#) lists the supported devices.

**Table 27-37. Supported NAND Devices**

Capacity	Device ID	Bus Width	Page Size in Bytes
512 Mb	F0h	8	2048
512 Mb	C0h	16	2048
512 Mb	A0h	8	2048
512 Mb	B0h	16	2048
512 Mb	F2h	8	2048
512 Mb	C2h	16	2048
512 Mb	A2h	8	2048
512 Mb	B2h	16	2048
1 Gb	F1h	8	2048
1 Gb	C1h	16	2048
1 Gb	A1h	8	2048
1 Gb	B1h	16	2048
2 Gb	DAh	8	2048
2 Gb	CAh	16	2048
2 Gb	AAh	8	2048
2 Gb	BAh	16	2048
2 Gb	83h	8	2048
2 Gb	93h	16	2048
4 Gb	DCh	8	2048
4 Gb	CCh	16	2048
4 Gb	ACh	8	2048/4096
4 Gb	BCh	16	2048/4096
4 Gb	84h	8	2048
4 Gb	94h	16	2048
8 Gb	D3h	8	2048/4096
8 Gb	C3h	16	2048/4096
8 Gb	A3h	8	2048/4096
8 Gb	B3h	16	2048/4096
8 Gb	85h	8	2048
8 Gb	95h	16	2048
16 Gb	D5h	8	2048/4096
16 Gb	C5h	16	2048/4096
16 Gb	A5h	8	2048/4096
16 Gb	B5h	16	2048/4096
16 Gb	86h	8	2048

**Table 27-37. Supported NAND Devices (continued)**

Capacity	Device ID	Bus Width	Page Size in Bytes
16 Gb	96h	16	2048
32 Gb	D7h	8	2048/4096
32 Gb	C7h	16	2048/4096
32 Gb	A7h	8	2048/4096
32 Gb	B7h	16	2048/4096
32 Gb	87h	8	2048
32 Gb	97h	16	2048
64 Gb	DEh	8	2048/4096
64 Gb	CEh	16	2048/4096
64 Gb	AEh	8	2048/4096
64 Gb	BEh	16	2048/4096

After retrieving parameters from the table, the page size and block size are updated based on the fourth byte of the NAND ID data. Because of inconsistency among manufacturers, only devices recognized to be at least 2Gb have these parameters updated. Therefore, the ROM code supports 4-KB page devices, but only if their size, according to the table, is at least 2Gb. Devices that are smaller than 2Gb have the block size parameter set to 128KB (when the page size is 2KB).

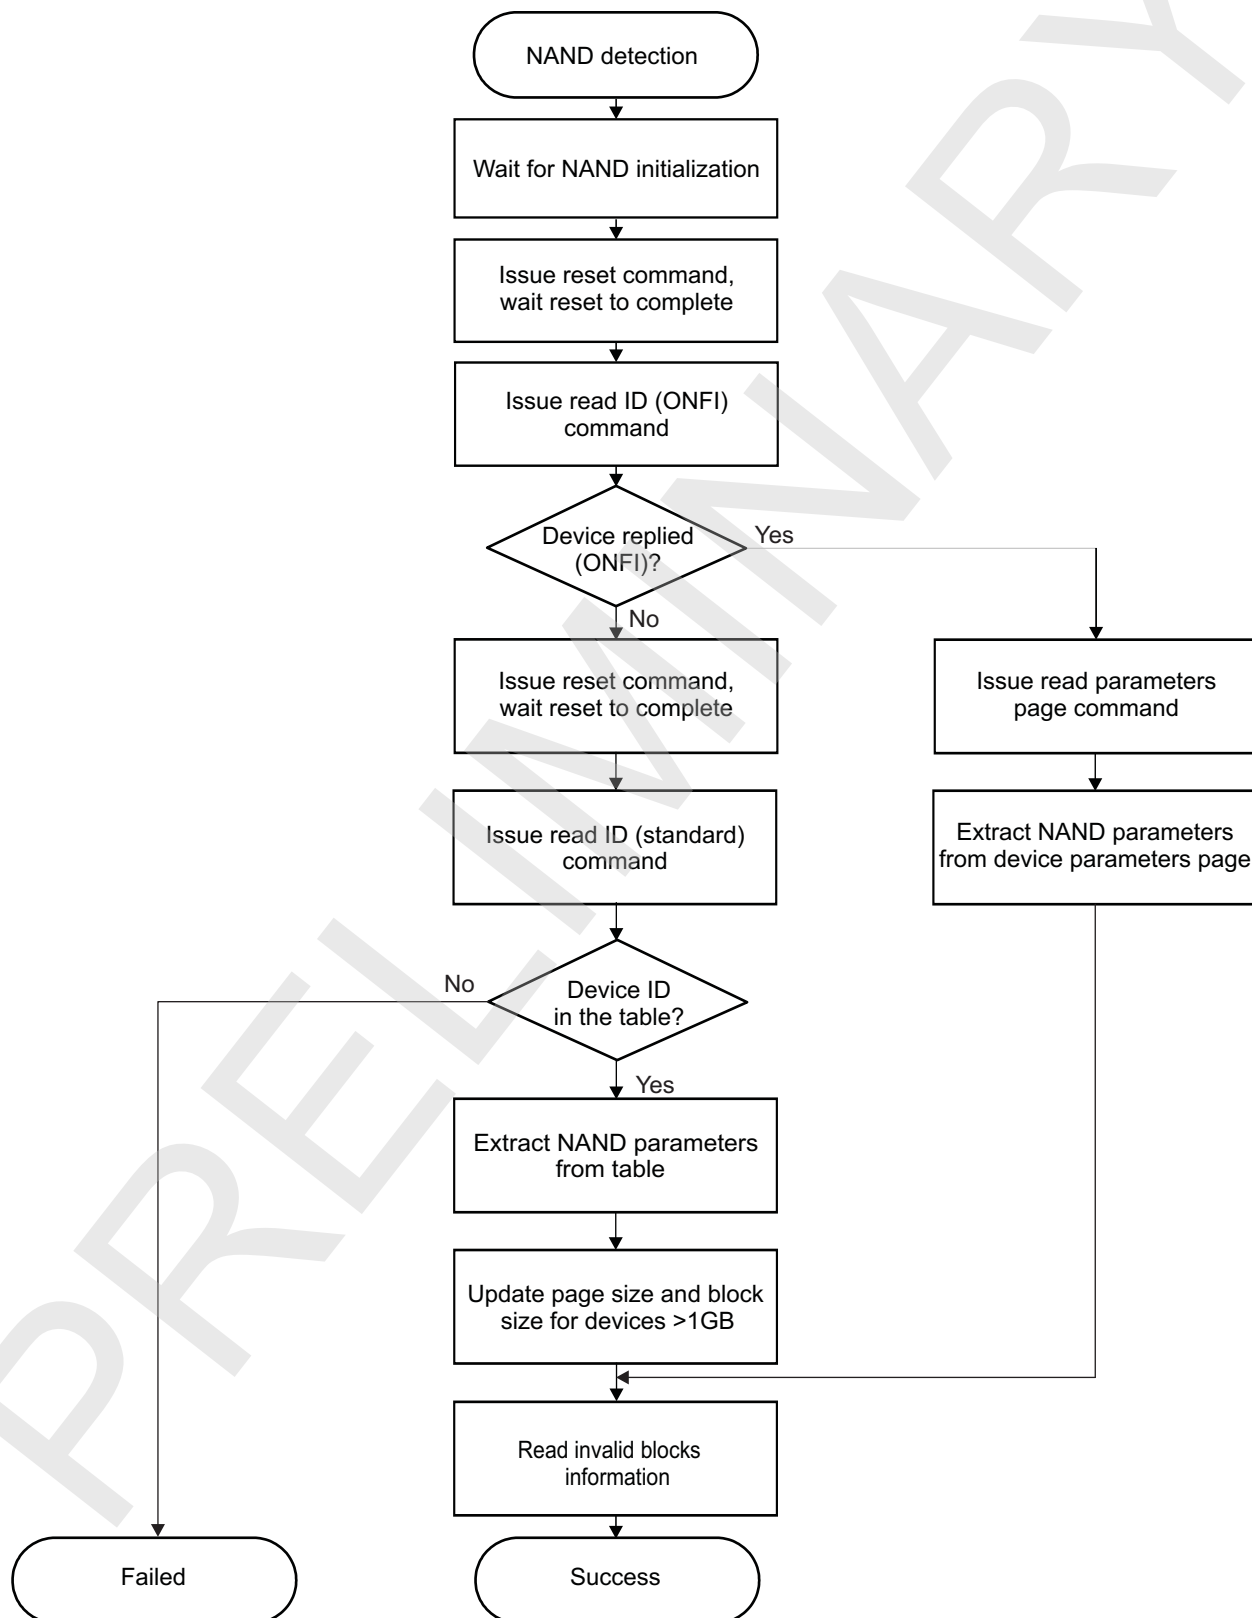

[Table 27-38](#) shows the fourth ID data byte encoding used in the ROM code.

**Table 27-38. Fourth NAND ID Data Byte**

Item	Description	I/O Number							
		7	6	5	4	3	2	1	0
<b>Page Size</b>	1KB							0	0
	2KB							0	1
	4KB							1	0
	8KB							1	1
<b>Cell type</b>	2 levels						0	0	
	4 levels						0	1	
	8 levels						1	0	
	16 levels						1	1	
<b>Block Size</b>	64KB				0	0			
	128KB				0	1			
	256KB				1	0			
	512KB				1	1			

Figure 27-21 shows the detection procedure. Once the NAND device is successfully detected, the ROM code changes the GPMC to 16-bit bus width, if necessary.

**Figure 27-21. NAND Device Detection**

init-023

- **Bad block verification**  
 Invalid blocks contain invalid bits whose reliability cannot be ensured by the manufacturer. These bits are identified in the factory or during the programming and reported in the initial invalid block information in the spare area on the first and second page of each block. Because the ROM code looks for an image in the first four blocks, it detects the validity status of these blocks. Blocks detected as invalid are not accessed later. Block validity status is coded in the spare areas of the first two pages of a block (first byte equal to FFh in the first and second pages for an 8-bit device/first word equal to FFFFh in the first and second pages for a 16-bit device).

Figure 27-22 shows the invalid block detection routine. The routine consists in reading spare areas and checking the validity data pattern.

**Figure 27-22. Bad NAND Invalid Block Detection**

init-033

**27.4.7.4.2 Read Sector Procedure**

During the booting procedure, the ROM code reads 512-byte sectors from the NAND device. The reading fails in two cases:

- The accessed sector is in a block marked as invalid.
- The accessed sector contains an error that cannot be corrected with ECC.

The ROM code uses normal read (command 00h 30h) for reading NAND page data.

Page data can contain errors caused by memory alteration. The ROM code uses an ECC correction algorithm to detect and possibly correct those errors. The default ECC correction applied is BCH 8b/sector using the GPMC and ELM hardware.

For device ID codes D3h, C3h, D5h, C5h, D7h, C7h, DEh, CEh when the manufacturer code (first ID byte) is 98h, the cell type information is checked in the 4th byte of ID data. If it is equal to 10b, the ECC correction applied is BCH 16b/sector.

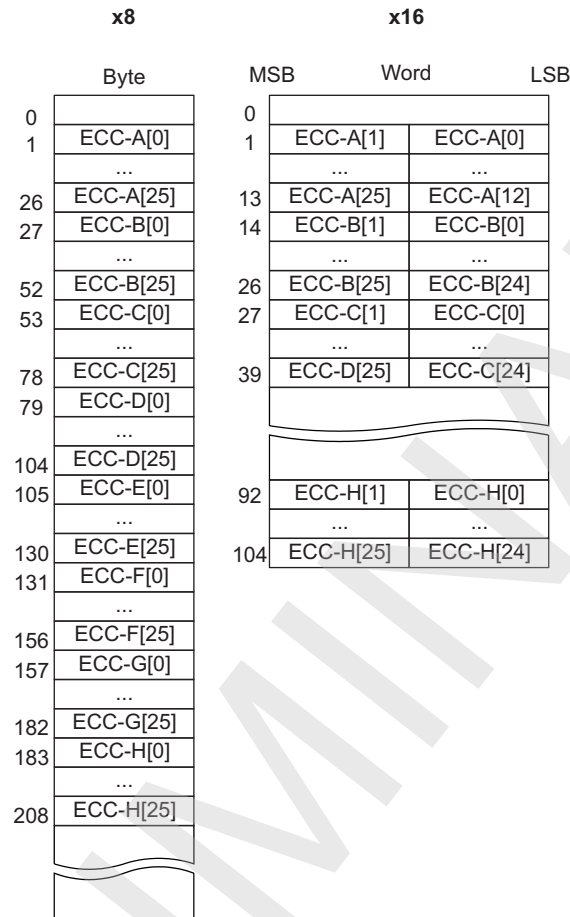

The BCH data is automatically calculated by the GPMC on reading each 512-byte sector. The computed ECC is compared against the ECC stored in the spare area for the corresponding page. Depending on the page size, the amount of ECC data bytes stored in the corresponding spare area is different. [Figure 27-23](#) and [Figure 27-24](#) show the mapping of ECC data inside the spare area for 2KB-page and 4KB- page devices, respectively. If both ECC data are equal, the read sector function returns the read 512-byte sector without error. Otherwise, the ROM code tries to correct error(s) in the corresponding sector (this procedure is assisted by the ELM hardware) and returns the data if successful. If errors are uncorrectable, the function returns with FAIL.

**Figure 27-23. ECC Data Mapping for 2-KB Page and 8b BCH Encoding**

init-040

Figure 27-24. ECC Data Mapping for 4-KB Page and 16b BCH Encoding

init-041

### 27.4.7.5 OneNAND/Flex-OneNAND

The ROM code support for OneNAND/Flex-OneNAND devices has the following characteristics:

- Devices from 512 Mbits
- The GPMC is the communication interface.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- GPMC reset default timings are used.
- The GPMC clock is 50 MHz.
- The device is connected to GPMC CS0 mapped to address 0x0800 0000.
- The wait-pin signal gpmc\_wait0 is not monitored.
- Four physical blocks are searched for image. The block size is 128KB (typically).
- Data correction is fully handled by the OneNAND/FlexOneNAND device

The OneNAND/Flex-OneNAND device is a NAND matrix coupled with RAM buffers and a NOR-type interface. ECC correction handling is done automatically by the internal state-machine. The page to be accessed is first loaded in the RAM buffer using memory-mapped registers. Then, the page is read directly from the buffer using a NOR-type interface.

For OneNAND/Flex-OneNAND memory booting, no user intervention is required. The information in the following sections is included for debugging. Only the CH, which is not mandatory, lets users change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

#### 27.4.7.5.1 Initialization and OneNAND/Flex-OneNAND Detection

The initialization routine for OneNAND/Flex-OneNAND consists of two parts: GPMC initialization and device detection with parameter determination.

- GPMC initialization

The ROM code first initializes the GPMC interface in XIP mode (that is, asynchronous 16-bit multiplexed mode). Wait signal monitoring is disabled.

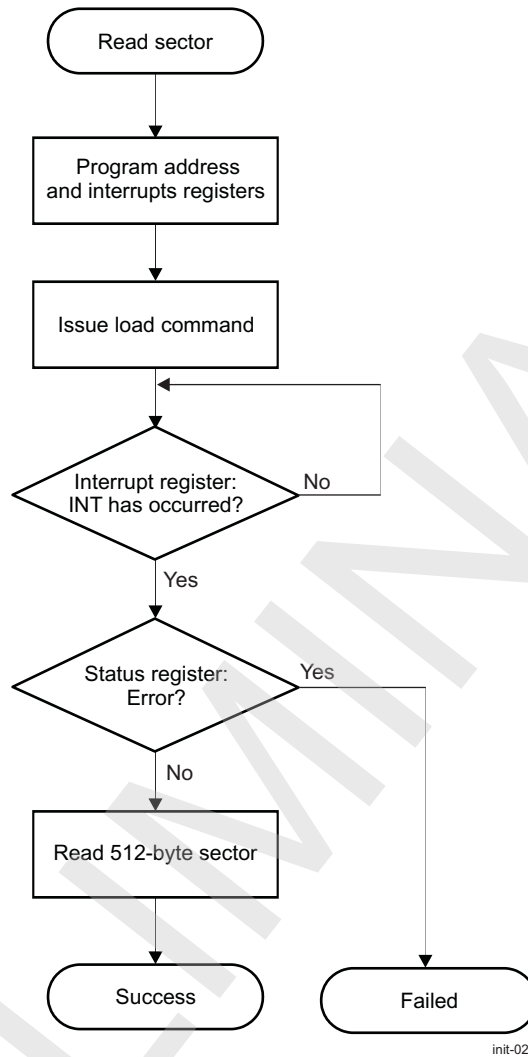

- Device detection and parameters

The ROM code identifies a OneNAND/Flex-OneNAND device by reading the device identification data. There are two ways to read identification data: using serial commands and reading from fixed memory-mapped registers. The ROM code reads identification data using both methods and compares the results. When the comparison passes, the ROM code assumes that the OneNAND/Flex-OneNAND device is connected. If the device is successfully recognized, the ROM code reads the device configuration (number and size of data buffers) and configures it for asynchronous mode (default).

#### 27.4.7.5.2 OneNAND/Flex-OneNAND Read Sector Procedure

When booting requests a sector from the OneNAND/Flex-OneNAND device, the ROM code performs the load operation, which transfers the content of the requested sector to the data buffer RAM. The ROM code waits until the operation completes, polling the OneNAND/Flex-OneNAND interrupt register. The status register is then checked and the ROM code returns FAIL if the operation completes with an error. Otherwise, the data buffer RAM is copied to the destination buffer. [Figure 27-25](#) shows this procedure.

Figure 27-25. OneNAND/Flex-OneNAND Read Sector

**27.4.7.5.3 OneNAND/Flex-OneNAND Support Limitations**

As described in [Section 27.4.7.5.1, Initialization and OneNAND/Flex-OneNAND Detection](#), the ROM code checks only the coherency of the device ID obtained by two different methods. There is no table of supported Flex-OneNANDs in ROM code. This removes any dependency of the ROM code on device IDs from different manufacturers. However, the driver works with the following assumption:

- Page size is assumed to be 2048 bytes, divided into four sectors of 512 bytes. In case of OneNAND/Flex-OneNAND, with pages of 4096 bytes in size, divided into eight sectors, users must program only the first sectors (sectors 0, 1, 2, 3) of each page. Sectors 4, 5, 6, and 7 of each page are not considered by the driver.

**27.4.7.6 eMMC/eSD Embedded Memories and MMC/SD Cards**

The OMAP4430 device allows booting from eMMC/eSD embedded memories or MMC/SD cards connected to SD/MMC1 or SD/MMC2. The booting interface is selected by configuration of the sys\_boot pins.

The HS MMC/SD/SDIO host controllers (MMCHS) handle the physical layer, while the ROM code handles the simplified logical protocol layer (read-only protocol). A limited range of commands is implemented in the ROM code.

The MMC interface 1 supports 1.8V/3V digital I/Os. The selection on I/O voltage level is done using the PBIAS circuitry. The PBIAS reference level is sensed by the ROM code and PBIAS cell voltage setup appropriately before any communication with the device. The MMC interface 2 supports only 1.8-V digital I/Os.

The OMAP4430 device supports two booting modes:

- Raw: The booting image data is read directly from sectors in the user area.
- File system (FAT12/16/32 supported with or without master boot record): The image data is read from a booting file.

When using the SDMMC1 interface, raw and file system modes are supported. When using the SDMMC2 interface, only raw mode is supported. The purpose of this approach is to avoid the boot time penalty of searching for a file system hierarchy when it is not always necessary.

[Figure 27-26](#) shows the complete procedure.

Figure 27-26. eMMC/eSD and MMC/SD Booting

init-016

### 27.4.7.6.1 eMMC/eSD Overview

The ROM code supports eMMC/eSD cards, with the following conditions:

- eMMC devices compliant with *Embedded MultiMediaCard (eMMC) eMMC/Card Product Standard, High Capacity, including Reliable Write Boot, and Sleep Modes, Dual Data Rate, Multiple Partitions Supports and Security Enhancement v4.4* from the MMCA Technical Committee. The exception is the hardware reset feature. If the user requires hardware reset, it can be accomplished with a GPIO.
- eSD devices compliant with *SD Specification Part 1 eSD (Embedded SD) Specification Addendum v2.1* from the SD Card Association
- The eMMC/eSD memory device is powered externally by a power-management IC or other power

supply.

- Initial 1-bit MMC mode, optional 4-bit or 8-bit modes.
- Clock frequency:
  - Identification mode: 400 kHz
  - Data transfer mode: Up to 10 MHz, optionally up to 19.2 MHz
- Only one memory connected to the bus

#### 27.4.7.6.1.1 System Conditions and Limitations

The ROM code does not support the specific details of the partition management and boot operations modes as defined in the eMMC Standard sections *Partition Management* and *Boot Operation Mode*. The booting image is assumed to be located in the User Data Area (no use of boot and/or RPMB partitions). Customers must set up the eMMC device appropriately so that the booting image is located in a reliable area within the User Data Area (possibly with the Enhanced User Data Area property).

The ROM code does not provide a bus direction control signaling in case of using MMC interface 2 with level shifters.

The ROM code expects that the eMMC device is powered externally and supplies are set and stable upon entering the booting procedure. The ROM code does not perform any software action to the companion device with respect to powering the eMMC/eSD device.

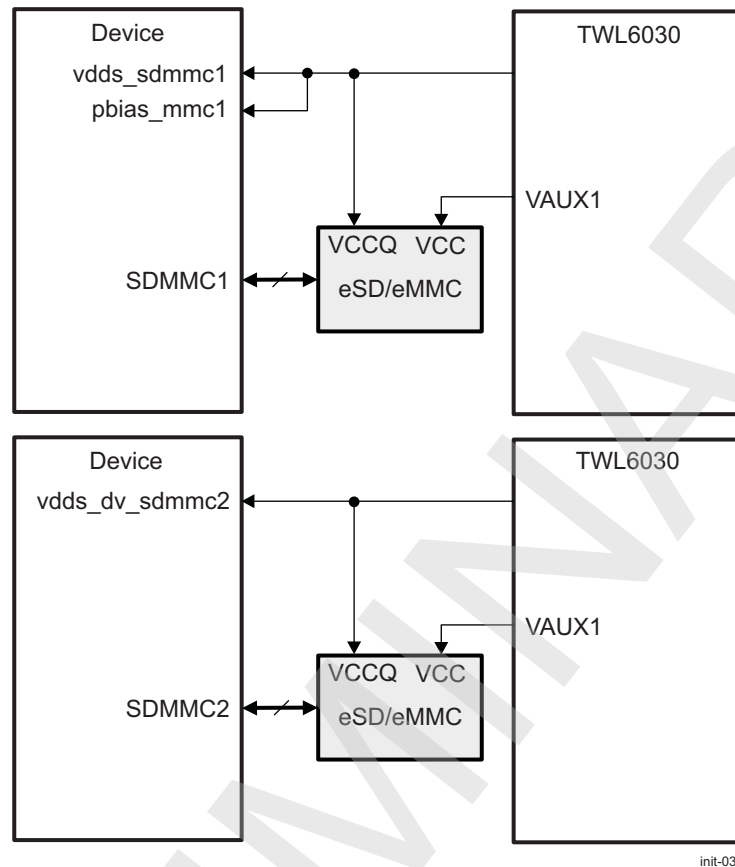

#### 27.4.7.6.1.2 eMMC/eSD Memory Connection

An eMMC/eSD device typically requires two supplies: one for the core memory array (selectable 1.8/2.9 V at TWL6030 BOOT2 pin level) (see TWL6030 documentation), and one for the device interface I/Os and controller (typical VCCQ = 1.8 V). Both memory device supply pins can possibly be merged into one, thus requiring only one power supply.

The SD/MMC2 interface shares the same balls as the GPMC interface. Therefore, the ROM code performs the necessary pin mux configuration to route the MMC signal through the GPMC balls.

[Figure 27-27](#) shows an example of the system connection between the power-management IC, memory device, and OMAP device.

Figure 27-27. eMMC/eSD Connection

The ROM code supports the muxing of the MMC interface 2 through two paths:

- GPMC pins in configuration mode 1 (Mux1)
- SDMMC5/FREF\_CLKx pins in Mux5

The ROM code performs the necessary I/O pin muxing configuration to route the MMC2 signals through the appropriate pins depending on the selected SYSBOOT configuration.

#### 27.4.7.6.2 MMC/SD Overview

The ROM code supports booting from MMC/SD cards under the following conditions:

- MMC/SD cards compliant with *The MultiMediaCard System Specification* from the MMCA Technical Committee and the *SD Memory Card Specifications, File System Specification* from the SD Association. These Include low- and high-capacity cards
- MMC/SD cards connected to SDMMC interface 1
- 3-V VCC power supply, support for 3-V or 1.8-V I/O voltages
- Initial 1-bit MMC mode, optional 4-bit or 8-bit modes
- Clock frequency:
  - Identification mode: 400 kHz
  - Data transfer mode: Up to 10 MHz (optionally up to 19.2 MHz)
- Only one card connected to the bus

##### 27.4.7.6.2.1 MMC/SD Card Connection

An SD/MMC card can be connected to the MMC1 interface, typically through a card cage. The ROM code sends the appropriate I<sup>2</sup>C sequence to the power-management IC to set the VMMC LDO to 3 V and switch it on.

Figure 27-28 shows the typical connection between the power IC, the card, and the OMAP device .

**Figure 27-28. MMC/SD Card Connection**

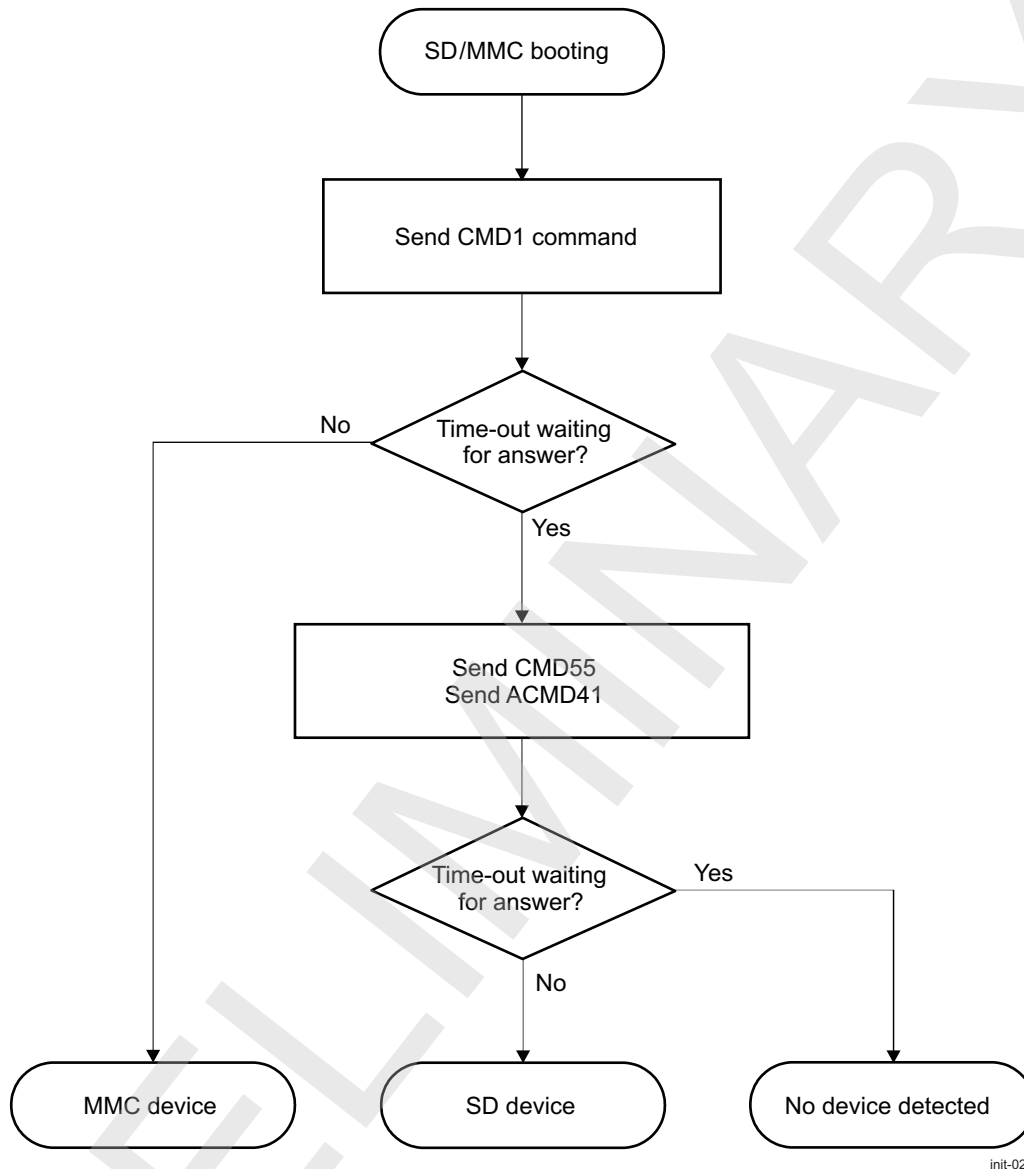

**NOTE:** The ROM code does not handle the card detection feature on the card cage.

#### 27.4.7.6.3 Initialization and Detection

The ROM code initializes the memory device or card connected on the interface using the standard high-voltage range (3.0 V). If neither a card or memory device is detected, the ROM code moves on to the next booting device. The standard identification process and relative card address (RCA) assignment are used. However, the ROM code assumes that only one memory or card is connected on the bus. This is done using the CMD line common to the SD and MMC memory devices. The MMC and SD standards describe this phase as the initialization phase. They differ in the first commands involved, CMD1 and ACMD41. The ROM code uses this command difference to discriminate between MMC and SD cards; that is, CMD1 is only supported by the MMC standard and ACMD41 is only supported by the SD standard. The ROM code first sends a CMD1 to the device and gets an answer only if an MMC device is connected. If no response is received, ACMD41 (a combination of CMD55 and ACMD41) is sent, and an response is expected from an SD device. If no response is received, no devices are connected and the ROM code exits MMC/SD booting with FAIL.

Figure 27-29 shows the MMC/SD detection procedure.

Figure 27-29. MMC/SD Detection Procedure

init-026

#### 27.4.7.6.4 Read Sector Procedure

- Raw mode

In raw mode, an image can be located at one of the four consecutive locations in the main area: offset 0x0 (0KB)/0x20000 (128KB)/0x40000 (256KB)/0x60000 (384KB). For this reason, the size of a booting image must not exceed 128KB. However, a device with an image greater than 128KB can be flash starting at one of the aforementioned locations. Therefore, the ROM code does not check the image size. The only drawback is that the image crosses the subsequent image boundary. Raw mode is detected by reading sectors 0, 256, 512, and 768. The content of these sectors is verified for the presence of a TOC structure. For a GP device, a CH (if used) must be located in the first sector followed by a GP header. The CH can be void (containing only a CHSETTINGS item for which the Valid field is 0), as described in [Section 27.4.8.2, Configuration Header](#). Image data is read directly from continuous sectors of a card. If raw mode is not detected, file system mode is assumed.

- File system handling

File system support is available only for SDMMC1 interface. The sector read procedure uses the standard MMC/SD read data procedure. The sector address is generated based on the booting

memory file map collected during initialization. Thus, the ROM code can freely address sectors in the booting file space.

#### 27.4.7.6.5 File System Handling

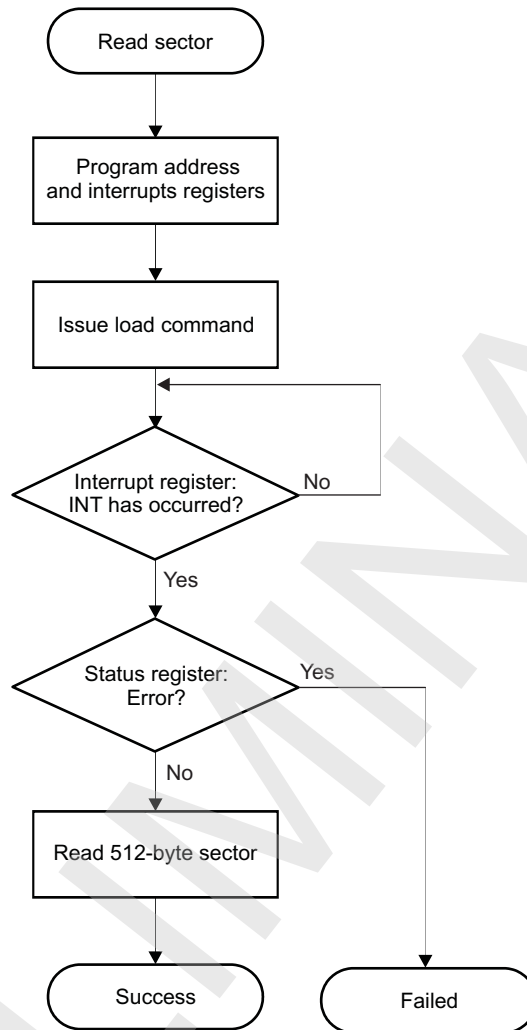

The MMC/SD cards can hold a file system that the ROM code reads. The image used by the booting procedure is taken from a booting file named MLO. This file must be in the root directory on an **active** primary partition of type FAT12/16 or FAT32.

An MMC/SD card can be configured as floppy-like or hard-drive-like:

- When acting like a floppy, the content of the card is a single FAT12/16/32 file system without an MBR holding a partition table.
- When acting like a hard drive, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary, and active.

According to the *MultiMediaCard FAT16 File System Specification* from the MMCA Technical Committee, the card must always hold an MBR, except for MMC cards using a floppy-like file system. However, depending on the operating system used, the MMC/SD card is formatted with or without partition(s) (using an MBR). The ROM code supports both types: floppy-like or hard-drive-like. The ROM code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT table entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512-byte sector in the booting file without involving the ROM code FAT module. [Figure 27-30](#) shows the complete process.

Figure 27-30. SD/MMC Get Booting File

init-025

### 27.4.7.6.5.1 MBR and FAT File System

This paragraph describes functions used by the ROM code to recognize whether an MBR with a FAT is used. It is not intended to fully describe the MBR and the FAT file system detection and reading procedure. The ROM code can detect FAT12/16/32 allocation table types. It cannot boot on devices with NTFS or Linux® FS partitions. Some memory devices that support file systems can be formatted with or without MBR; therefore, the first task of the ROM code is to detect whether the device is holding an MBR in the first sector.

The MBR is the first sector of a memory device. It consists of executable code, four partition entries, and one signature. The aim of such a structure is to divide the hard disk in partitions used primarily to boot different systems (for instance, Microsoft Windows™). This structure is described in [Table 27-39](#), and the partition table entry is described in [Table 27-40](#).

**Table 27-39. Master Boot Record Structure**

Offset	Length (Bytes)	Entry Description
0000h	446	Optional code
01BEh	16	Partition table entry
01CEh	16	Partition table entry
01DEh	16	Partition table entry
01EEh	16	Partition table entry
01FEh	2	Signature (0xAA55)

**Table 27-40. Partition Table Entry**

Offset	Length [Bytes]	Entry Description	Value
0000h	1	Partition state	00h: Inactive 80h: Active
0001h	1	Partition start head	Hs
0002h	2	Partition start cylinder and sector	Cs[7:0]-Cs[9:8]-Ss[5:0]
0004h	1	Partition type	01h: FAT12 04h, 06h, 0Eh: FAT16 0Bh, 0Ch, 0Fh: FAT32
0005h	16	Partition end head	He
0006h	2	Partition end cylinder and sector	Ce[7:0]-Ce[9:8]-Se[5:0]
0008h	4	First sector position relative to the beginning of media	LBAs = Cs.H.S+ Hs.S+ Ss-1
000Ch	4	Number of sectors in partition	LBAe = Ce.H.S+ He.S+ Se-1 Nb s= LBAe-LBAs + 1

SD/MMC booting consists of the following steps:

#### Step 1. MBR detection

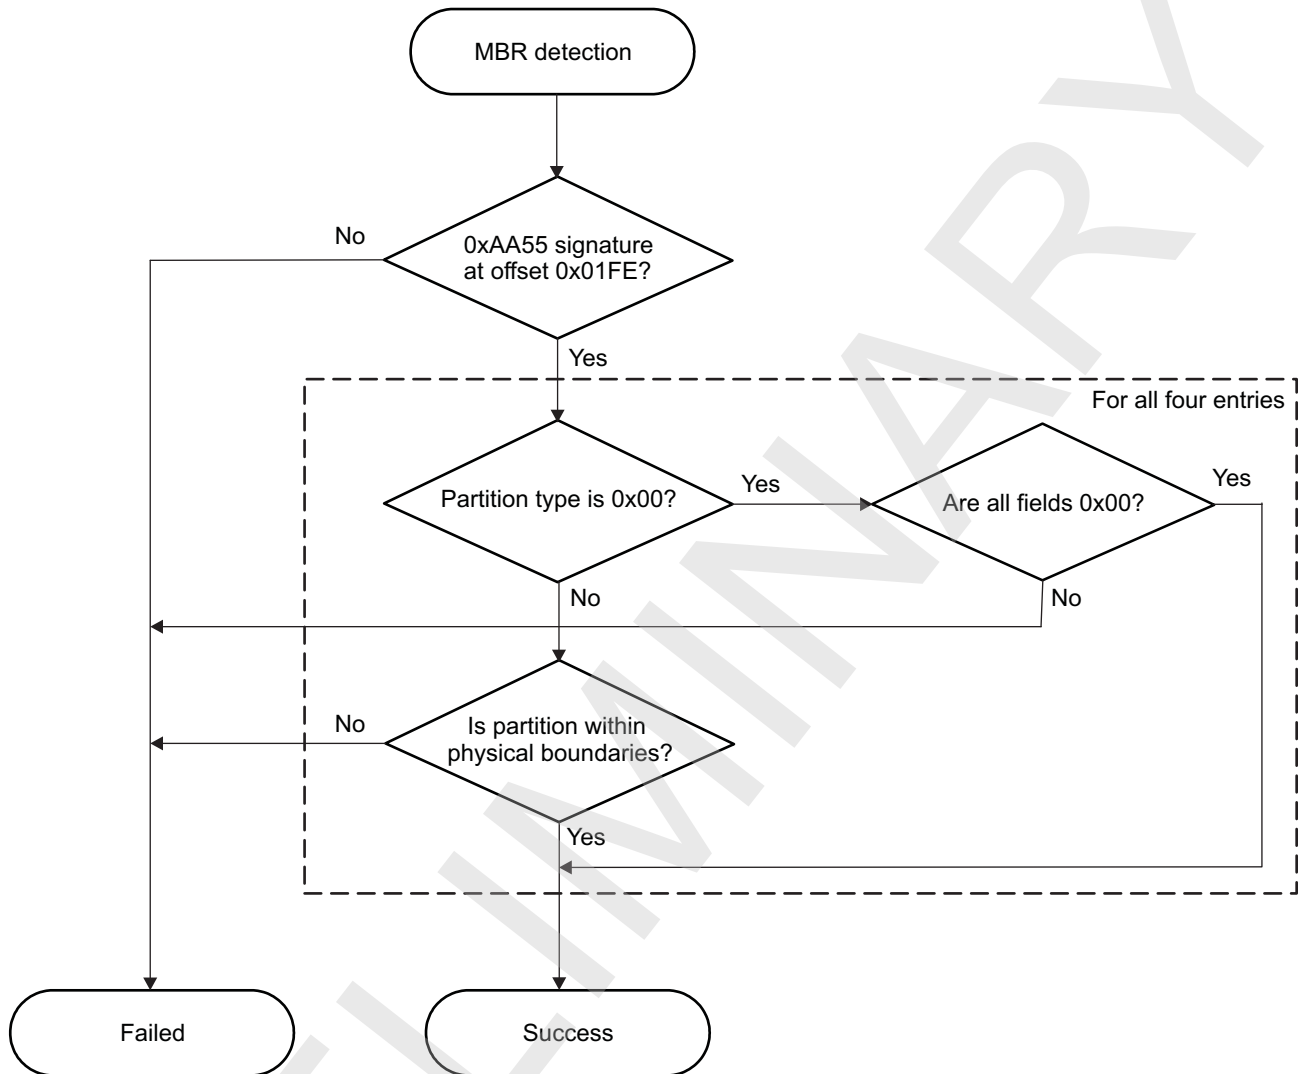

The ROM code first checks whether the MBR signature is present, and then it searches an active FAT12/16/32 partition in all four MBR partition entries, based on the type field. If the MBR entries are not valid, or if no usable partition is found, the ROM code returns to the booting procedure with FAIL. The extended partitions are not checked; the booting file must reside in a primary partition. Each partition entry is checked:

- (a) If its type is set to 00h, all fields in the entry must be 00h.
- (b) The partition is checked to be within physical boundaries (that is, the partition is inside and it fits the total physical sectors).

See [Figure 27-31](#) for more information about MBR detection.

Figure 27-31. MBR Detection Procedure

init-028

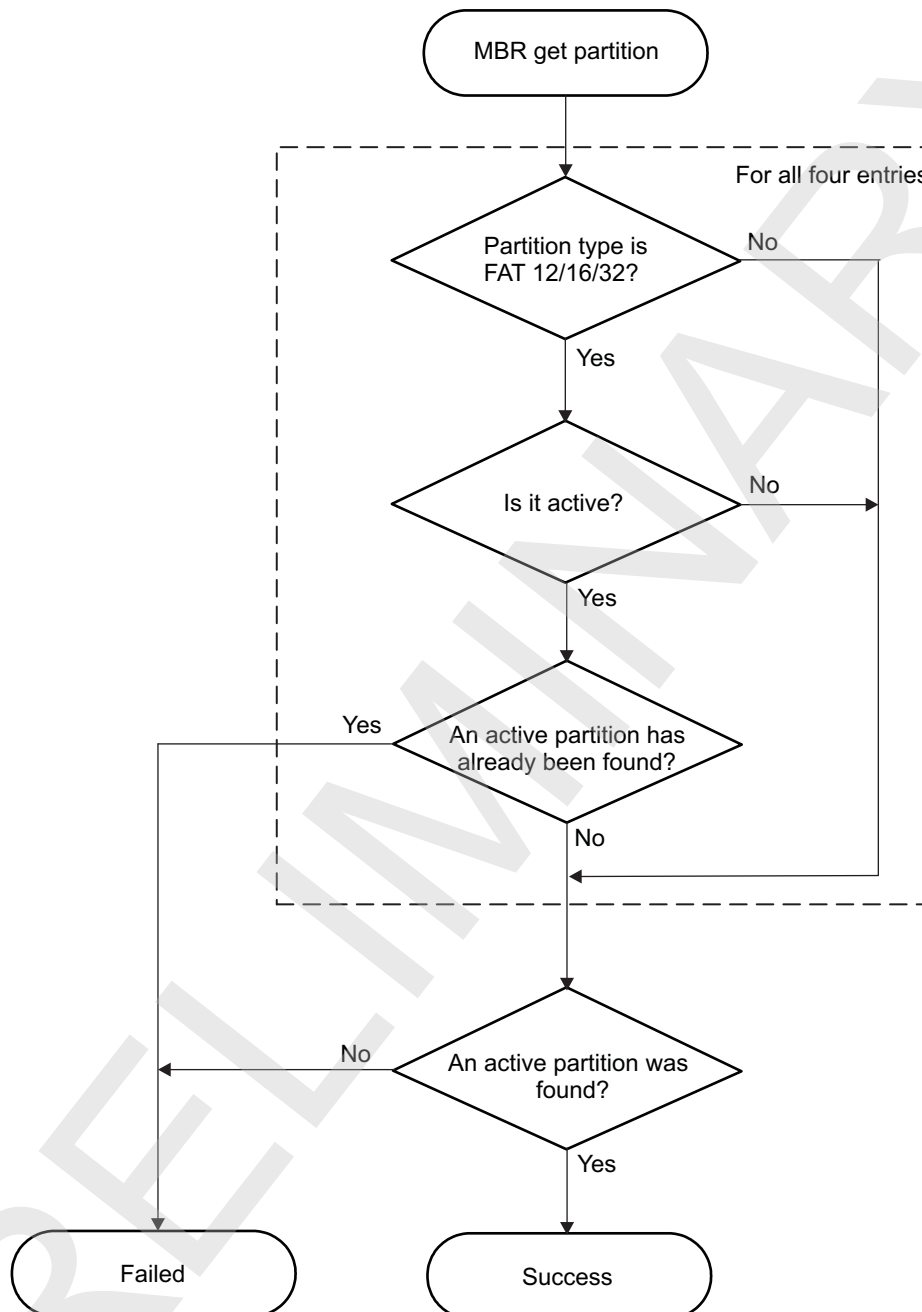

Step 2. Get the MBR partition.

Once identified, the ROM code gets the partition using the procedure described in Figure 27-31. The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h (inactive) or 80h (active.) The ROM code returns with FAIL if no active primary FAT12/16/32 is found, or the test fails if there is more than one active partition. If an active partition is found, its first sector is read and used later. If no MBR is present (in case of a floppy-like system), the first sector of the device is read and used later. The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, the ROM code returns with FAIL if another partition type is used (for instance, Linux FS) or if the partition is not valid.

The FAT file system consists of several parts:

- Boot sector, which holds the BIOS parameter block (BPB). Not all are used by the ROM code.
- FAT, which describes the use of each cluster of the partition
- Data area, which holds the files, directories, and root directory (for FAT12/16, the root directory has a specific fixed location)

To check whether a sector holds a valid FAT12/16/32 partition, many fields of the boot sector (used by all FAT types) that must have specific values are checked. Figure 27-32 shows more about getting the partition.

**Figure 27-32. MBR, Get Partition**

init-029

**Step 3. Find the booting file.**

When a partition is found, the root directory entries are searched for a booting file named MLO in the root directory of the FAT12/16/32 file system. The file is not searched in any other location. For a FAT12/16 file system, the root directory has a fixed location, which is cluster 0. For a FAT32 file system, its cluster location is given by BPB\_RootClus. The formula to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by the following equation:

$$\text{Cluster}_{\text{sector}} = \text{BPB\_HiddSec} + \text{BPB\_RsvdSecCnt} + \text{BPB\_NumFATs} \cdot \text{BPB\_FATSz} + \text{Cluster} \cdot \text{BPB\_SecPerCLus}$$

init-E001

**NOTE:** BPB\_FatSz is BPB\_FatSz16 for FAT12/16, or BPB\_FatSz32 for FAT32.

**NOTE:** The BPB\_HiddSec field can contain 0, even though the FAT file system is somewhere other than on sector 0 (floppy-like). The ROM code uses the partition offset taken from the MBR instead of this field, which can be wrong. If no MBR is found (floppy-like), the value 0 is used.

Each entry in the root directory is 32 bytes and holds information about the file (the filename, date of creation, rights, cluster location, etc.). (See [Table 27-41](#).)

**Table 27-41. FAT Directory Entry**

Offset	Length [Bytes]	Name	Description
0000h	11	DIR_Name	Short Name (8 + 3)
000Bh	1	DIR_Attr	File Attributes: 01h - ATTR_READ_ONLY 02h - ATTR_HIDDEN 04h - ATTR_SYSTEM 08h - ATTR_VOLUME_ID 10h - ATTR_DIRECTORY 20h - ATTR_ARCHIVE 0Fh - ATTR_LONG_NAME
000Ch	1	DIR_NTRes	Reserved. Set to 00h
000Dh	1	DIR_CrtTimeTenth	Millisecond stamp at file creation
000Eh	2	DIR_CrtTime	Time file was created.
0010h	2	DIR_CrtDate	Date file was created.
0012h	2	DIR_LstAccDate	Last access date
0014h	2	DIR_FstClusHi	High word of the first cluster number of this entry
0016h	2	DIR_WrtTime	Time of last write
0018h	2	DIR_WrtDate	Date of last write
001Ah	2	DIR_FstClusLo	Low word of the first cluster number of this entry
001Ch	4	DIR_FileSize	File size in bytes

The ROM code checks each entry in the root directory until either the booting file is found or the entry is empty (first byte is 00h), or when the end of the root directory is reached. Entries with the ATTR\_LONG\_NAME attribute (LFN) and first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR\_FstClusHi/DIR\_FstClusLo fields. There is a slight difference between FAT12/16 and FAT32 when handling the root directory. On FAT12/16, this directory has a fixed location (see above) and length fixed by BPB\_RootEntCnt, which is the total of 32-byte entries. Handling this directory is therefore straightforward. On FAT32, the root directory is like a standard file. The FAT must be used to retrieve each sector of the directory. The way in which the FAT is handled is described in the following paragraph.

#### Step 4. Buffer FAT entries in the FAT buffer

When the booting file is found, the ROM code reads the FAT and buffers the singly-linked chain of clusters in a FAT buffer used by booting to access the file directly, sector by sector. For FAT12/16 and for FAT32, multiple copies of the FAT exist (ROM code supports only two copies), after the boot sector.

$$FATn_{sector} = BPB\_HiddSec + BPB\_RsvdSecCnt + BP\_FatSz \cdot n$$

init-E002

The size of the FAT buffer is given by BPB\_FATsZ16 or BPB\_FATsZ32. The ROM code checks each copy of the FAT if they are identical. If the values are different, the ROM code uses the value from the last FAT copy. With the FAT32 file system, the copy system can be disabled according to a flag in BPB\_ExtFlags[7]. If this flag is set, the FAT BPB\_ExtFlags[3:0] bit field is used. In this case, no verification is made by the ROM code with other copies of FAT.

The FAT is a simple array of values, each referring to a cluster located in the data area. One entry of the array is 12, 16, or 32 bits, depending on the file system in use. The value in an entry defines whether the cluster is being used or not, and if another cluster must be considered. This creates a

singly-linked chain of clusters defining the file. The meaning of an entry is described in [Table 27-42](#).

**NOTE:** For compatibility, cluster 0 and cluster 1 are not used for files, and these entries must contain:

- FF8h and FFFh (for FAT12)
- FFF8h and FFFFh (for FAT16)
- 0FFFFFFF8h and 0FFFFFFFh (for FAT32)

**Table 27-42. FAT Entry Description**

FAT12	FAT16	FAT32	Description
000h	0000h	00000000h	Free cluster
001h	0001h	00000001h	Reserved cluster
002h-FEFh	0002h- FFEFh	00000002h- 0FFFFFFEFh	Used cluster; value points to next cluster
FF0h-FF6h	FFF0h- FFF6h	0FFFFFFF0h- 0FFFFFFF6h	Reserved values
FF7h	FFF7h	0FFFFFFF7h	Bad cluster
FF8h-FFFh	FFF8h- FFFh	0FFFFFFF8h- 0FFFFFFFh	Last cluster in file

**NOTE:** FAT32 uses only bits [27:0]; the upper 4 bits are usually 0 and must be left untouched.

When accessing the root directory for FAT32, the ROM code starts from the root directory cluster entry and follows the linked chain to retrieve the clusters.

When the booting file has been found, the ROM code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors, depending on how many sectors are in a cluster (BPB\_SecPerClus). This buffer is used later by the booting procedure to access the file.

#### 27.4.7.7 LPDDR2-NVM

The OMAP4430 device allows booting from a LPDDR2-NVM device connected to the EMIF interface. After setup, the NVM device can be accessed in XIP mode and instructions fetched directly through the EMIF interface (similarly as the XIP/NOR-like interfaces described in [Section 27.4.7.3, XIP Memory](#)).

Features:

- XIP addressable
- Uses EMIF as the communication interface
- Up to 2-GB memories can be connected
- x32 data bus width only
- Supports 4/8 row data buffers of 32/64 bytes
- EMIF DDR clock frequency at boot time is 50 MHz
- Device connected to EMIF1/CS1, mapped at address C000000h

##### 27.4.7.7.1 Initialization and Detection

[Figure 27-25](#) shows the initialization and detection procedure.

Figure 27-33. EMIF LPDDR2-NVM Detection and Initialization

init-043

The ROM code first performs basic initialization of the EMIF controller and prepares for communication through EMIF1/CS1. The clock frequency at device boundary (ck pin) has been setup during the clocks setup (see [Section 27.4.4.2, Clocking Configuration](#)) to be 50 MHz (as defined as the upper boundary of the JEDEC specification for boot).

The device auto-initialization (DAI) status bit in Mode Register 0 (MR0) is polled for completion of device auto-initialization. This must complete within a 5-ms timeframe. If not, the initialization procedure returns with FAIL and the ROM code moves to the next device in the booting list. The MR0 device information (DI) bit reflects whether the attached device is an NVM device.

Then, the ROM code sends a ZQ calibration command (mode register write to MR10) and waits for completion (simple wait for 100  $\mu$ s). If the DI bit is set (it has been detected during the auto-initialization sequence), the ROM code determines the number and size of row data buffers and sets up the EMIF controller accordingly. Additionally, the NVM registers of the EMIF controller are updated with appropriate NVM timings.

The DMM (LISA map section 1) is set up to open a 2-GB window from system address C0000000h. This leaves the possibility for using a CHRAM configuration header to enable further SDRAM access.

The last steps consist in sending three configuration commands for:

- Block length setup, burst sequence, wrapping, and nWR (MR1)
- Read/write latency (MR2)
- I/O strength (MR3)

[Table 27-43](#) summarizes the list of mode registers used during NVM device configuration.

**Table 27-43. Summary of Mode Register Commands**

Mode Register (JEDEC Name)	Read/Write	Use
MR0 (Device_info)	MRR	Polling for auto-initialization and NVM device type determination
MR1 (Device_Feature1)	MRW	Block length setup (BL = 8), sequential burst (default), wrap enable (default), nWR = 3 (default)
MR2 (Device_Feature2)	MRW	Read/Write latency (RL = 3 / WL = 1, default)
MR3 (IO_Config1)	MRW	I/O strength (40 $\Omega$ , default)
MR8 (Basic_Config4)	MRR	I/O width determination (not used currently) <sup>(1)</sup>
MR10 (IO_Calibration)	MRW	ZQ calibration (FFh, calibration command after initialization)
MR20 (NVM_Geometry)	MRR	Determination of number and size of row data buffers

<sup>(1)</sup> The MR8 register is read for I/O width determination; however, no specific action is performed with this information. The device is assumed to be 32 bits wide.

## 27.4.8 Image Format

### 27.4.8.1 Overview

An image has two major parts:

- An optional CH
- Software to execute

The CH can contain several parameters set by users to speed up booting. It is further described in [Section 27.4.8.2, Configuration Header](#).

The mandatory part contains the software that is loaded into the memory and executed.

[Figure 27-34](#) is an overview of the boot image formats. There are two image types:

1. GP non-XIP memory booting: This image type is used for memories that require shadowing (for example, MMC). An image can contain a CH that includes at least a CHSETTINGS item entry. Next, there must be a small header (referred to as a GP header) that contains information about the size and the destination address.

- When the memory device is of XIP type (for example, NOR), the GP header is not required, and the image can contain code for direct execution. Optionally, the first sector can contain a CH. The same image format is used for peripheral booting (where the code is transferred to internal RAM).

**Figure 27-34. Image Formats**

init-018

### 27.4.8.2 Configuration Header

The CH is optional and is required only if the customer wants to use settings different from the ROM code defaults (for example, clock frequencies, EMIF, GPMC, or MMCHS interfaces).

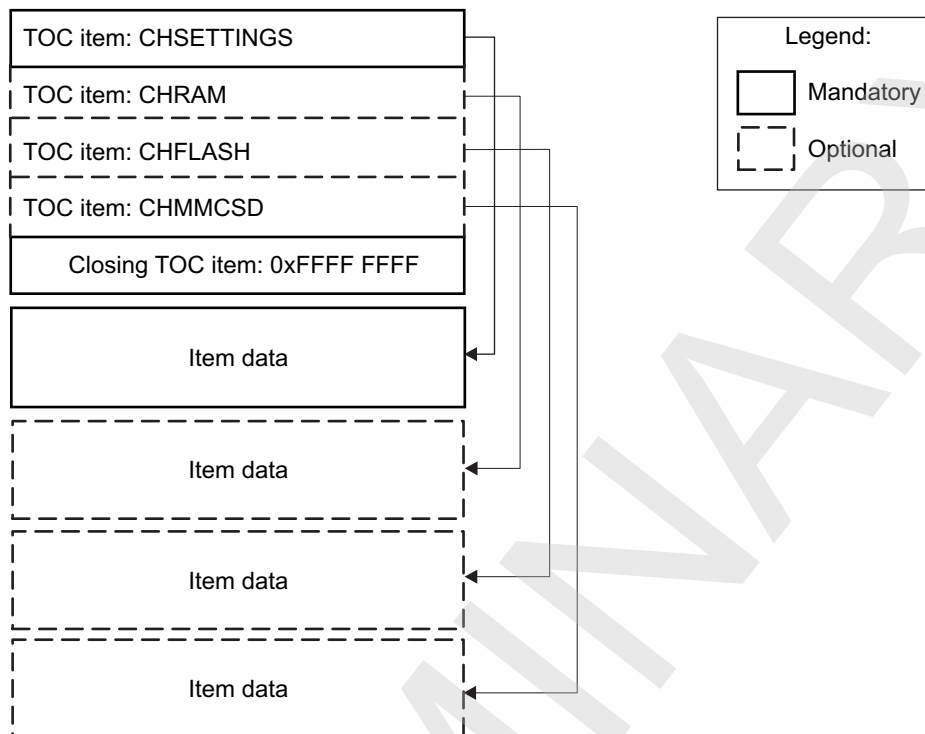

The CH can contain the following parts:

- Settings: Various clock settings (mandatory)
- RAM: EMIF settings
- FLASH: Flash interface (GPMC) settings
- MMC/SD: MMCHS interface settings

The beginning of the CH is a table of contents (TOC), which points to each item. This is described in [Figure 27-35](#). Each TOC item is a simple structure described in [Table 27-44](#). The complete CH (CH TOC and items) should fit in a 512-byte sector.

The ROM code identifies the presence of a CH by reading the first TOC item if it contains a known string (CHSETTINGS, CHRAM, etc.). Next, the TOC is identified and searched until a 0xFFFFFFFF offset is found. The CH is read and parameters are executed sequentially.

For the sake of simplicity, each field represents the content of a register to be modified. Only fields required for the configuration are used; fields for status, for instance, are not modified and therefore are not shown in the tables.

**Figure 27-35. CH Format**

init-019

**Table 27-44. CH TOC Item**

Offset	Field	Size (Bytes)	Description
0x0000	Start	4	Offset from the start address of the TOC to the actual address of item contents
0x0004	Size	4	Size of item
0x0008	Reserved	4	Unused
0x000C	Reserved	4	Unused
0x0010	Reserved	4	Unused
0x0014	Filename	12	12-character name of a item, including the zero (0) termination character

### 27.4.8.2.1 CHSETTINGS Item

The CHSETTINGS configuration header contains settings specific to the clock system. The ROM code configures the OMAP clocking to some default settings as described in [Section 27.4.4.2, Clocking Configuration](#). The CH CHSETTINGS section contains a method to override the ROM code default clock settings.

[Table 27-45](#) describes the fields. The clocking procedure and the clocking setting structure are described in [Section 27.4.4.4, Software Booting Configuration](#).

**Table 27-45. CHSETTINGS Item**

Offset	Field	Description
0000h	Section key	Key used for item verification: C0C0C0C1h
0004h	Valid	Enables/disables the section 00h: Disable Others: Enable

**Table 27-45. CHSETTINGS Item (continued)**

Offset	Field	Description
0005h	Version	Configuration header version 0001h Others: Reserved
0006h	Reserved	
0008h	Clocking settings	Described in <a href="#">Table 27-13</a> , <i>Software Booting Configuration Structure</i> , starting from the FLAGS field.

### 27.4.8.2.2 CHRAM Item

The CHRAM configuration header contains settings specific to the SDRAM memory controller (EMIF). [Table 27-46](#) describes the fields. The ROM code does not configure the EMIF by default, because it cannot assume any external SDRAM type. Therefore, if the ROM code is needed to configure the SDRAM access, the user must provide the appropriate timing details in the CHRAM structure. For more information, see [Section 15.3](#), *EMIF Controller*, and [Section 15.3.6](#), *EMIF Register Manual*.

**Table 27-46. CHRAM Item**

Offset	Field	Description
0000h	Section key	Key used for section verification: C0C0C0C2h.
0004h	Valid	Enables/disables the section: 00h: Disable Other: Enable
0005h	Reserved	
0008h	SdramConfig (EMIF1)	SDRAM configuration register
000Ch	SdramRefresh (EMIF1)	SDRAM Refresh control register
0010h	SdramTim1 (EMIF1)	SDRAM timing 1 register
0014h	SdramTim2 (EMIF1)	SDRAM timing 2 register
0018h	SdramTim3 (EMIF1)	SDRAM timing 3 register
001Ch	PwrMgtCtrl (EMIF1)	Power management control register
0020h	DdrPhyCtrl1 (EMIF1)	DDR PHY control 1 register
0024h	DdrPhyCtrl2 (EMIF1)	DDR PHY control 2 register
0028h	ModeReg1 (EMIF1)	Mode register MR1
0029h	ModeReg2 (EMIF1)	Mode register MR2
002Ah	ModeReg3 (EMIF1)	Mode register MR3
002Bh	Reserved	
002Ch	SdramConfig (EMIF2)	SDRAM configuration register
0030h	SdramRefresh (EMIF2)	SDRAM refresh control register
0034h	SdramTim1 (EMIF2)	SDRAM timing 1 register
0038h	SdramTim2 (EMIF2)	SDRAM timing 2 register
003Ch	SdramTim3 (EMIF2)	SDRAM timing 3 register
0040h	PwrMgtCtrl (EMIF2)	Power management control register
0044h	DdrPhyCtrl1 (EMIF2)	DDR PHY control 1 register
0048h	DdrPhyCtrl2 (EMIF2)	DDR PHY control 2 register
004Ch	ModeReg1 (EMIF2)	Mode register MR1
004Dh	ModeReg2 (EMIF2)	Mode register MR2
004Eh	ModeReg3 (EMIF2)	Mode register MR3
004Fh	Reserved	
0050h	DMM LISA Map 0	DMM LISA section 0 mapping (see <a href="#">Section 15.2</a> for more information about the DMM module architecture)

**Table 27-46. CHRAM Item (continued)**

Offset	Field	Description
0054h	Flags	Setting bits 0 to 3 requests ROM code to configure the appropriate channel/chip select: Bit[0]: Configure EMIF1 CS0 Bit[1]: Configure EMIF1 CS1 Bit[2]: Configure EMIF2 CS0 Bit[3]: Configure EMIF2 CS1 Other bits: Reserved

**NOTE:**

- The ROM code supports only the LPDDR2 memory type (as set in the SDRAM configuration register).
- It is assumed that the same kind of SDRAM (same type and timings) is attached to both CSs when requesting the configuration of both CSs for a given EMIF (for example, if bit 0 and 1 of the flags field are set, it is assumed that both EMIF1 CSs are attached to the same kind of memory).

**27.4.8.2.3 CHFLASH Item**

The CHFLASH configuration header contains settings specific to the general-purpose memory controller (GPMC). For more information, see [Section 15.4, GPMC Overview](#). [Table 27-47](#) describes the fields.

**Table 27-47. CHFLASH Item**

Offset	Field	Description
0000h	Section Key	Key used for section verification: C0C0C0C3h.
0004h	Valid	Enables/disables the section: 00h: Disable Others: Enable
0005h	Reserved	
0008h	GPMC_SYSCONFIG (LSB)	Register values
000Ah	GPMC_IRQENABLE (LSB)	
000Ch	GPMC_TIMEOUT_CONTROL (LSB)	
000Eh	GPMC_CONFIG (LSB)	
0010h	GPMC_CONFIG1_0	
0014h	GPMC_CONFIG2_0	
0018h	GPMC_CONFIG3_0	
001Ch	GPMC_CONFIG4_0	
0020h	GPMC_CONFIG5_0	
0024h	GPMC_CONFIG6_0	
0028h	GPMC_CONFIG7_0	
002Ch	GPMC_PREFETCH_CONFIG1	
0030h	GPMC_PREFETCH_CONFIG2 (LSB)	
0032h	GPMC_PREFETCH_CONTROL (LSB)	
0034h	GPMC_ECC_CONFIG	
0036h	GPMC_ECC_CONTROL	
0038h	GPMC_ECC_SIZE_CONFIG (LSB)	
003Ch	Enable_A1_A10	0: Do not change A1– A10 pads Others: Enable A1 – A10 pads

#### 27.4.8.2.4 CHMMCS D Item

The CHMMCS D configuration header contains settings specific to the high-speed MMC/SD/SDIO host controller (MMCHS). For more information, see [Chapter 24, MMC/SD/SDIO](#). [Table 27-48](#) describes the fields.

**Table 27-48. CHMMCS D Item**

Offset	Register Modified	Description
0000h	Section key	Key used for section verification C0C0C0C4h
0004h	Valid	Enables/disables the section 00h: Disable Other: Enable
0005h	Reserved	
0008h	MMCHS_SYSCTRL(MSW)	Update MMCHS_SYSCTRL interface register with the value specified in these fields. The register is not updated if the value is 0xFFFFFFFF.
000Ah	MMCHS_SYSCTRL(LSW)	
000Ch	MMCHS interface bus width	1: 1 bit 2: 4 bits 4: 8 bits 0xFFFF FFFF: Do not update bus width. Others: Reserved

The ROM code provides a booting parameter structure to the Initial software (see [Section 27.4.8.4, Image Execution](#)). This structure contains a field that indicates whether the configuration header items have been correctly processed. For a CHMMCS D item, if the MMCHS\_SYSCTRL and bus width fields are set to 0xFFFF FFFF, the booting parameters report that the CHMMCS D section has not been executed, regardless of the value of the Valid field.

#### 27.4.8.3 GP Header

When the booting memory device is non-XIP (for example, MMC) the image must contain a small header, located before the executable code, and having the size of the software to load and the destination address of where to store it. [Table 27-49](#) describes the image format. The GP header is not required when booting from an XIP memory device (for example, NOR) or in case of peripheral booting. In this case, the peripheral or memory booting image starts directly with executable code.

**Table 27-49. GP Header Format**

Field	Non-XIP Device Offset	XIP Device Offset	Size (Bytes)	Description
Size	0x0000	-	4	Size of the image
Destination	0x0004	-	4	Address where to store the image or code entry point
Image	0x0008	0x0000	x	Executable code

**NOTE:** The destination address field stands for:

- Target address for the image copy from the non-XIP storage to the target XIP location (for example, internal RAM or SDRAM)
- Entry point for image code

Users must take care to locate the code entry point to the target address for image copy.

#### 27.4.8.4 Image Execution

The image is executed at the time the ROM code performs the branch to the first executable instruction in the initial software. For a GP device in non-XIP, the execution address is the first word after the GP header. The branch is performed in public ARM supervisor mode. The R0 register points to the booting parameter structure that contains information about booting execution. [Table 27-50](#) shows the booting parameter structure.

**Table 27-50. Booting Parameter Structure**

Offset	Field	Size (Bytes)	Description
0x00	Booting message	4	Last received booting message
0x04	Memory booting device descriptor	4	Pointer to the memory device descriptor that has been used during the memory booting process
0x08	Current booting device	1	Code of device used for booting: 0x00: void, no device 0x02: XIP memory 0x02: XIPWAIT memory (wait-signal monitoring on) 0x03: NAND 0x04: OneNAND 0x05: MMC1 0x06: MMC2(1) 0x07: MMC2(2) 0x08: EMIF 0x43: UART3 0x45: USB (internal transceiver) 0x46: USB-ULPI Others: Reserved
0x09	Reset reason	1	Current reset reason bit mask (bit = 1, event present): [0]: Power-on reset [1]: Global software reset [3]: Violation reset [4]: MPU watchdog reset [5]: Watchdog reset [6]: External warm reset Other bits: Reserved
0x0A	CH flags	1	Configuration header items flag. Each item is described by 1 bit. A set bit indicates that the item was executed: [0]: CHSETTINGS [1]: CHRAM [2]: CHFLASH [3]: CHMMCS Other bits: Reserved

#### 27.4.9 Tracing

Tracing in the public ROM code consists in three 32-bit vectors for which each bit corresponds to a particular way point in the ROM code execution sequence. [Table 27-51](#) through [Table 27-53](#) list the organization of the tracing data in RAM. Tracing vectors are initialized at the beginning of the start-up phase and are updated all along the boot process.

There are two sets of tracing vectors ([Table 27-10](#)). The first set is the current trace information (after cold or warm reset). The second set holds a copy of trace vectors collected at the first ROM code run after cold reset. As a result, after a warm reset it is possible to have visibility on the boot scenario that occurred during cold reset.

[Table 27-51](#) lists the organization of tracing vector 1.

**Table 27-51. Tracing Vector 1**

Bit	Group	Meaning
0	General	Passed the public reset vector
1	General	Entered main function
2	General	Running after the cold reset
3	Boot	Main booting routine entered
4	Memory boot	Memory booting started
5	Peripheral boot	Peripheral booting started
6	Boot	Booting loop reached last device
7	Boot	GP header found
8	Boot	Booting message Skip peripheral booting received
9	Boot	Booting message Change device received
10	Peripheral boot	Booting message Peripheral booting received
11	Peripheral boot	Booting message Get ASIC ID received
12	Peripheral boot	Device initialized
13	Peripheral boot	ASIC ID sent
14	Peripheral boot	Image received
15	Peripheral boot	Peripheral booting failed
16	Peripheral boot	Booting message not received (time-out)
17	Peripheral boot	Image size not received (time-out)
18	Peripheral boot	Image not received (time-out)
19	Reserved	
20	Configuration header	CHSETTINGS found
21	Configuration header	CHSETTINGS executed

## 27.5 Services for HLOS Support

The ROM code provides different services that can be called on GP devices for L2 cache maintenance, wake up of slave CPU(s), etc. These services are implemented in monitor mode (the service must be called by writing the function ID into the R12 register and using the SMC instruction) and do not use any resources like RAM/stack or hardware outside the master CPU. The caller must ensure the save and restore of the processor registers before and after calling the monitor service.

The following code example shows how the monitor ROM code functions can be accessed by an application running in public mode:

```

;-----;
FUNCTION: PL310_SetDebugL2Cache
;
; DESCRIPTION: Function calls the Monitor Service to configure the debug
;              control register of the L2 cache.
;
; INPUTS: r0 Value to set in the debug control register
;
; RETURN:
;
;-----;
PL310_SetDebugL2Cache FUNCTION
    PUSH {R1-R12, LR}
    LDR R12, =API_MONITOR_L2CACHE_SETDEBUG_INDEX
    SMI 0x1 POP {R1-R12, PC}
    ENDFUNC

```

### 27.5.1 L2 Cache Maintenance

**Table 27-54. L2 Cache Write Debug Register**

Function ID	Description	
R12 = 0x100	Set the input parameter value in the L2 Cache Debug register	
Parameters		
Type	Location	Description
Input	R0	Debug register value to set
Output		
Return		

**Table 27-55. L2 Cache Clean and Invalidate Range of Physical Address**

Function ID	Description	
R12 = 0x101	This function cleans and invalidates a range Physical Addresses. This is a workaround of the clean and invalidate L2 cache.	
Parameters		
Type	Location	Description
Input	R0 R1	Physical Start Address of the range Size of the range to invalidate
Output		
Return		

**Table 27-56. Enable/Disable L2 Cache**

Function ID	Description	
R12 = 0x102	This function sets the given input value in the L2 Cache Control Register (enable/disable)	
Parameters		
Type	Location	Description
Input	R0	Control register value to set

**Table 27-56. Enable/Disable L2 Cache (continued)**

Function ID	Description
Output	
Return	

**Table 27-57. Write Auxiliary Control Register**

Function ID	Description	
R12 = 0x109	This function writes the PL310 Auxiliary Control Register with the input given value in R0.	
Parameters		
Type	Location	Description
Input	R0	Value to set in the register
Output		
Return		

**Table 27-58. Write Tag and Data RAM Latency Control Register**

Function ID	Description	
R12 = 0x112	This function writes the PL310 Tag and Data RAM Latency Control Register with the input given value in R0 and R1.	
Parameters		
Type	Location	Description
Input	R0 R1	Tag RAM latency to set Data RAM latency to set
Output		
Return		

**27.5.2 Multicore Infrastructure Maintenance**

**Table 27-59. Read AuxCoreBoot 0 and AuxCoreBoot 1 Register**

Function ID	Description	
R12 = 0x103	Read both AuxCoreBoot registers. This function is not necessary. It is kept for compatibility with ES1.0.	
Parameters		
Type	Location	Description
Input		
Output	R0 R1	AuxCoreBoot 0 register value AuxCoreBoot 1 register value
Return		

**Table 27-60. Modify AuxCoreBoot 0**

Function ID	Description	
R12 = 0x104	Modify the AuxCoreBoot 0 register used as a status bit. The function sets and clears the bit given in the parameter and returns the new register value after operation. This function is not necessary. It is kept for compatibility with ES1.0.	
Parameters		
Type	Location	Description
Input	R0 R1	Bit mask to set Bit mask to clear
Output		

**Table 27-60. Modify AuxCoreBoot 0 (continued)**

Function ID	Description	
Return	R0	AuxCoreBoot 0 register new value

**Table 27-61. Write AuxCoreBoot 1**

Function ID	Description	
R12 = 0x105	Set the value of the AuxCoreBoot 1 register value used to give the CPU1 boot address. The given address can be virtual or physical. CPU 1 MMU must be enabled before jumping to this address. This function is not necessary. It is kept for compatibility with ES1.0.	
Parameters		
Type	Location	Description
Input	R0	Value to set in the register
Output		
Return		

**Table 27-62. Read Control and Status Register**

Function ID	Description	
R12 = 0x106	Function returns the value of the WakeUpGen Control and Status register CPU 0 or CPU 1 depending on the input parameter value. This function is not necessary. It is kept for compatibility with ES1.0.	
Parameters		
Type	Location	Description
Input	R0	CPU ID
Output		
Return	R0	Value of the control and status register of the CPU ID

**Table 27-63. Clear Control and Status Register**

Function ID	Description	
R12 = 0x107	This function clears the given bit mask of the WakeUpGen Control and Status register of the given CPU ID.	
Parameters		
Type	Location	Description
Input	R0 R1	CPU ID Bit Mask to clear
Output		
Return		

### 27.5.3 Snoop Control Unit (SCU)

**Table 27-64. Set Power Status Register**

Function ID	Description	
R12 = 0x108	This function sets the power status register of the CPU and cleans the full CPU L1 data cache, if the cache will be switched OFF when CPU enters into low-power state.	
Parameters		
Type	Location	Description
Input	R0 R1	CPU power state value to set (0x2: CSWRET, 0x3: OFF) L1 data cache state (0x00: RET, 0xFF: OFF)

**Table 27-64. Set Power Status Register (continued)**

Function ID	Description
Output	
Return	

### 27.5.4 Lockdown Translation Lookaside Buffers (TLBs)

**Table 27-65. Select the TLB Entry for Read**

Function ID	Description	
R12 = 0x10A	This function writes the Select Lockdown TLB Entry for Read register.	
<b>Parameters</b>		
Type	Location	Description
Input	R0	TLB entry
Output		
Return		

**Table 27-66. Select the TLB Entry for Write**

Function ID	Description	
R12 = 0x10B	This function writes the Select Lockdown TLB Entry for Write register.	
<b>Parameters</b>		
Type	Location	Description
Input	R0	TLB entry
Output		
Return		

**Table 27-67. Read the TLB VA Entry**

Function ID	Description	
R12 = 0x10C	This function reads the Lockdown TLB VA register (Selected TLB Entry for Read).	
<b>Parameters</b>		
Type	Location	Description
Input		
Output		
Return	R0	Value of the register

**Table 27-68. Write the TLB VA Entry**

Function ID	Description	
R12 = 0x10D	This function writes the Lockdown TLB VA register (Selected TLB Entry for Write). The NS bit is forced to 1.	
<b>Parameters</b>		
Type	Location	Description
Input	R0	Value to write
Output		
Return		

**Table 27-69. Read the TLB PA Entry**

Function ID	Description	
R12 = 0x10E	This function reads the Lockdown TLB PA register (Selected TLB Entry for Read).	
Parameters		
Type	Location	Description
Input		
Output		
Return	R0	Value of the register

**Table 27-70. Write the TLB PA Entry**

Function ID	Description	
R12 = 0x10F	This function writes the Lockdown TLB PA register (Selected TLB Entry for Write).	
Parameters		
Type	Location	Description
Input	R0	Value to write
Output		
Return

## 28.1 Introduction

Debugging a system containing an embedded processor involves an environment that connects high-level debugging software, executing on a host computer, to a low-level debug interface supported by the target device. In between these levels is a debug and trace controller (DTC) that facilitates communication between the host debugger and the debug support logic on the target chip.

A combination of hardware and software that connects the host debugger to the target system, the DTC uses one or more hardware interfaces and/or protocols to convert actions dictated by the debugger user to JTAG commands and scans that execute the core hardware.

The debug software and hardware components let the user control multiple central processing unit (CPU) cores embedded in the device in a global or local manner. This environment provides:

- Synchronized global starting and stopping of multiple processors
- Starting and stopping of an individual processor
- Each processor can generate triggers that can be used to alter the execution flow of other processors.

System topics include but are not limited to:

- System clocking and power-down issues
- Interconnection of multiple devices
- Trigger channels

For easy integration into applications, a set of libraries (APIs) for debug-IP programming and software message library are being provided. More information about the APIs, download files, and other useful links for available libraries can be found on the CToolsLib Wiki site:

<http://processors.wiki.ti.com/index.php/CToolsLib>

CToolsLib is a collection of embedded target APIs/library focused to enable easy access to the chip tools (CTools), which are system-level debug facilities included in the debug subsystem capabilities of TI devices.

## 28.2 Debug Ports

### 28.2.1 IEEE1149.1

The target debug interface has the following signals:

- Five standard IEEE1149.1 JTAG signals: nTRST, TCK, TMS, TDI, and TDO
- A return clock (RTCK) due to the clocking requirements of the ARM968™ processor
- Two EMU [1:0] or five EMU [4:0] TI extensions, depending on the pin count (14 pins or 20 pins) in the JTAG header of the device.

Table 28-1 describes the IEEE1149.1 signals.

**Table 28-1. IEEE1149.1 Signals**

Pin Name	Internal Signal Name	Type <sup>(1)</sup>	Function	Description
jtag_nrst	nTRST	I	Test reset	When asserted (active low), causes all test and debug logic in the device to be reset along with the IEEE1149.1 interface
jtag_tck	TCK	I	Test clock	This is the test clock used to drive an IEEE1149.1 test access port (TAP) state-machine and logic. This is a free-running clock or a gated clock, depending on the DTC attached to the device and the RTCK monitoring.
jtag_rtck	RTCK	O	Returned (synchronized) test clock	Depending on the DTC attached to the device, either the JTAG signals are clocked from RTCK or the RTCK is monitored by the DTC to the gate TCK.
jtag_tms_tmisc	TMS	I	Test mode select	Directs the next state of the IEEE1149.1 TAP state-machine
jtag_tdi	TDI	I	Test data input	Scans data input to the device
jtag_tdo	TDO	O	Test data output	Scans data output by the device
dpm_emu0	EMU0	IO	Emulation 0	Channel 0 trigger OR boot mode OR trace port
dpm_emu1	EMU1	IO	Emulation 1	Channel 1 trigger OR boot mode OR trace port
dpm_emu2 <sup>(2)</sup>	EMU2 <sup>(2)</sup>	O	Emulation 2	Trace port
dpm_emu3 <sup>(2)</sup>	EMU3 <sup>(2)</sup>	O	Emulation 3	Trace port
dpm_emu4 <sup>(2)</sup>	EMU4 <sup>(2)</sup>	O	Emulation 4	Trace port

(1) I = Input; O = Output

(2) 20-pin JTAG header only

Table 28-2 specifies the OMAP4430 JTAG ID code, which can be accessed through the ICEPick module embedded in the debug subsystem.

**Table 28-2. OMAP4430 JTAG ID Code**

Device	F#	JTAG ID Code
OMAP4430	F78182	0xB852

### 28.2.2 IEEE1149.7

Besides the standard (legacy) JTAG mode of operation, the target debug interface can also be switched to a compressed JTAG (cJTAG) mode of operation, commonly referred to as IEEE1149.7 standard. An IEEE1149.7 adapter module runs a 2-pin communication protocol on top of an IEEE1149.1 JTAG TAP. The debug-IP logic serializes the IEEE1149.1 transactions, using a variety of compression formats, to reduce the number of pins needed to implement a JTAG debug port. The OMAP4430 device implements only a subset of the IEEE1149.7 protocol (see Table 28-4).

**NOTE:** At power-on-reset (POR), the default debug interface mode is IEEE1149.1. See the IEEE1149.7 specification for the scan sequence required to switch modes.

The IEEE1149.7 communication protocol can switch between serial and parallel formats. The parallel

format consists of the IEEE1149.1 signals, TCK, TMS, TDI, TDO, nTRST, and a RTCK return clock, if stalls are required. The serial format uses two signals, TCK and TMSC. The values of the TMS, TDI, TDO, and RTCK signals are multiplexed on the bidirectional pin, jtag\_tms\_tmsc, by the Debug-IP logic. Each TCK of the DTC is serialized into a packet, which is transmitted to the IEEE1149.7 adapter, where it is converted back to parallel. The TDO and RTCK information are returned during the packet transmission.

**NOTE:** Only MScan, Oscan0, and Oscan4 formats can be used if the device requires stalls.

Table 28-3 describes the IEEE1149.7 signals.

**Table 28-3. IEEE1149.7 Signals**

Pin Name	Internal Signal Name	Type <sup>(1)</sup>	Function	Description
jtag_tck	TCK	I	Test clock	This is the test clock used to drive an IEEE1149.1 TAP state-machine and logic. This is a free-running clock or a gated clock, depending on the DTC attached to the device and the TMSC RDY field monitoring.
jtag_tms_tmsc	TMSC	I/O	Test mode control and data scan	Compressed JTAG packet. The TMSC signal is driven only when the TCK signal is low. The signal level must be maintained by a keeper while the TCK signal is high.

(1) I = Input; O = Output

Table 28-4 summarizes the IEEE1149.7 features subset supported by the OMAP4430 device.

**Table 28-4. IEEE1149.7 Features Subset**

	IEEE1149.7 Feature	Device Support	Comment
<b>Configuration</b>	Class 4 TAP	✓	Supports 2-pin operation
	Class 5 TAP	–	No BDx or CDx channel
<b>Optional Components</b>	FRST	–	Functional reset (done via ICEPick)
	TRST	–	Test reset
	RDBK capability	✓	Read back of register data
	Aux Pin Functions	–	Reuse of TDI and TDO pins
	TCKWID	✓	Programmable TCK width
<b>Scan Formats</b>	JScan0	✓	Parallel mode
	JScan1	✓	Parallel with firewall
	JScan2	✓	Parallel with super-bypass select
	JScan3	✓	Parallel with register select
	SScan0	–	Segmented scan
	SScan1	–	Segmented scan + stalls
	SScan2	–	Segmented scan
	SScan3	–	Segmented scan + stalls
	Oscan0	✓	Support stalls
	Oscan1	✓	Nonstall mode
	Oscan2	✓	Bidirectional transfers
	Oscan3	✓	Host to target only
	Oscan4	✓	Support stalls
	Oscan5	✓	Pipelined
	Oscan6	✓	Bidirectional transfers
Oscan7	✓	Host to target only	
Mscan	✓	Multi devices mode + stalls	
<b>Power Control</b>	Power down logic	–	Handled by ICEMelter

### 28.2.3 Trace Port

On-chip debug and trace events can be exported to external equipment through the trace port in the device. The following exportable debug events and trace sources are supported:

- Debug events
  - Triggers. For more information about triggers, see [Section 28.4.2, Cross-Triggering](#).
- Trace sources
  - Processor trace: Cortex-A9 MPU trace supported by program trace macrocell (PTM) and trace port interface unit (TPIU) modules. For more information about processor trace, see [Section 28.7, Processor Trace](#).
  - System trace: Trace coming from various system Instrumentation modules and supported by system trace module (STM). For more information about system trace, see [Section 28.8, System Instrumentation](#).

Note that not all debug and trace features can be supported concurrently due to limited amount of pins allocated to debug. Thus, a multiplexing among debug and trace sources is implemented. The configuration and the debug/trace source selection are done through the debug resource manager (DRM) module embedded in the debug subsystem.

[Table 28-5](#) describes the trace port signals.

**Table 28-5. Trace Port Signals**

Pin Name	Internal Signal Name	I/O	Description
dpm_emu19	EMU19	O	Debug resource manager pin 19
dpm_emu18	EMU18	O	Debug resource manager pin 18
dpm_emu17	EMU17	O	Debug resource manager pin 17
dpm_emu16	EMU16	O	Debug resource manager pin 16
dpm_emu15	EMU15	O	Debug resource manager pin 15
dpm_emu14	EMU14	O	Debug resource manager pin 14
dpm_emu13	EMU13	O	Debug resource manager pin 13
dpm_emu12	EMU12	O	Debug resource manager pin 12
dpm_emu11	EMU11	O	Debug resource manager pin 11
dpm_emu10	EMU10	O	Debug resource manager pin 10
dpm_emu9	EMU9	O	Debug resource manager pin 9
dpm_emu8	EMU8	O	Debug resource manager pin 8
dpm_emu7	EMU7	O	Debug resource manager pin 7
dpm_emu6	EMU6	O	Debug resource manager pin 6
dpm_emu5	EMU5	O	Debug resource manager pin 5
dpm_emu4	EMU4	O	Debug resource manager pin 4
dpm_emu3	EMU3	O	Debug resource manager pin 3
dpm_emu2	EMU2	O	Debug resource manager pin 2
dpm_emu1	EMU1	I/O	Debug resource manager pin 1
dpm_emu0	EMU0	I/O	Debug resource manager pin 0

**NOTE:** The dpm\_emu[19:0] pins are shared with other functional (application) pins on the device boundary. To use the dpm\_emu[19:0] pins, user must program the device application pin manager (control module) appropriately. For more information, see [Chapter 18, Control Module](#).

For more information about DRM multiplexing and concurrent debug modes, see [Section 28.9, Concurrent Debug Modes](#).

### 28.2.4 End Product

For an end product phone, there are usually severe connectivity constraints and the standard debug ports may not be available at board level. This could make it difficult to trace and debug software.

To ease the process of tracing and debugging, a Narrow Interface for Debug and Test (NIDnT) concept defined by MIPI is used. NIDnT is based on IEEE1149.7 and STM interfaces and re-uses application interface pins. In the context of the OMAP4430 device, the application interface that can serve as a NIDnT port is the MMC1 interface. To use the NIDnT port, the relevant MMC1 pins must be set to the appropriate MUX mode through control module.

Table 28-6 shows the NIDnT port re-using MMC interface pins along with the corresponding MUX modes.

**Table 28-6. NIDnT Port Reusing MMC Interface Pins**

Module	Control Module Multiplexing		
	MUX0 (MMC)	MUX2 (STM)	MUX4 (IEEE1149.7)
Extension card (MMC)	sdmmc1_clk	dpm_emu19	–
	sdmmc1_cmd	uart1_rx	–
	sdmmc1_dat0	dpm_emu18	–
	sdmmc1_dat1	dpm_emu17	–
	sdmmc1_dat2	dpm_emu16	jtag_tms_tmssc
	sdmmc1_dat3	dpm_emu15	jtag_tck

**NOTE:** The nTRST signal must be driven high for the MMC1 interface to be used for IEEE1149.7 protocol.

**NOTE:** Uart1\_rx is an optional return channel. Depending on the trace receiver, the return channel is implemented by IEEE1149.1/IEEE1149.7.

For more information about how to configure the proper MUX mode, see [Chapter 18, Control Module](#).

For more information about the NIDnT concept, see *MIPI Alliance Test and Debug – NIDnT-Port* specification.

## 28.3 Debugger Connection

### 28.3.1 ICEPick Module

The debugger connects to the OMAP4430 device through its JTAG interface. The first level of debug interface seen by the debugger is the IEEE1149.7 adapter connected to the ICEPick module embedded in the debug subsystem.

---

**NOTE:** ICEPick version D (ICEPick-D) is used in the OMAP4430.

---

System-on-chip (SoC) designs typically have multiple processors, each having a JTAG test access port (TAP) embedded in the processor. The ICEPick module manages these TAPs and the power, reset, and clock controls for modules that have TAPs.

The ICEPick module is visible only from the debugger point of view, and thus cannot be programmed by application software. The debugger can configure ICEPick through its own TAP controller. The ICEPick TAP has an instruction length of 6 bits and is the primary TAP. It is always visible in the scan chain and is used to control and monitor the other secondary TAPs.

ICEPick provides the following debug capabilities:

- Debug connect logic for enabling or disabling most ICEPick instructions
- Dynamic TAP insertion
  - Serially linking up to 16 TAP controllers
  - Individually selecting one or more of the TAPs for scan without disrupting the instruction register (IR) state of other TAPs
- Power, reset, and clock management
  - Provides the power and clock states of each domain
  - Provides debugger control of the power domain of a processor. Can force the domain power and clocks on, and prohibit the domain from being clock-gated or powered down while a debugger is connected.
  - Applies system reset
  - Provides wait-in-reset (WIR) boot mode
  - Provides global and local WIR release
  - Provides global and local reset blocking

The ICEPick module implements a connect register, which must be configured with a predefined key to enable the full set of JTAG instructions. Once the debug connect key has been properly programmed, ICEPick signals and subsystems emulation logics should be turned on.

For more information about ICEPick dynamic TAP insertion, see [Section 28.3.3, Dynamic TAP Insertion](#).

For more information about ICEPick power, reset, and clock management features, see [Section 28.5, Power, Reset, and Clock Management Debug Support](#).

### 28.3.2 Boot Modes

The initial configuration of ICEPick is determined by the level of the dpm\_emu0 and dpm\_emu1 pins upon POR release. At POR, dpm\_emu0 and dpm\_emu1 are automatically configured as inputs. The dpm\_emu0 and dpm\_emu1 pins are free once POR has been released.

[Table 28-7](#) summarizes the ICEPick boot modes.

**Table 28-7. ICEPick Boot Modes Upon POR**

dpm_emu1	dpm_emu0	TAPs in the TDI → TDO Path	Other Effects/Comments
0	0	None	Reserved (do not use)
0	1	None	Reserved (do not use)
1	0	ICEPick	TAP only + wait-in-reset mode
1	1	ICEPick	TAP only (default mode)

### 28.3.2.1 Default Boot Mode

In ICEPick-only configuration, none of the secondary TAPs are selected. The ICEPick TAP is the only TAP between device-level TDI and TDO pins. This is the recommended boot mode.

### 28.3.2.2 Wait-In-Reset

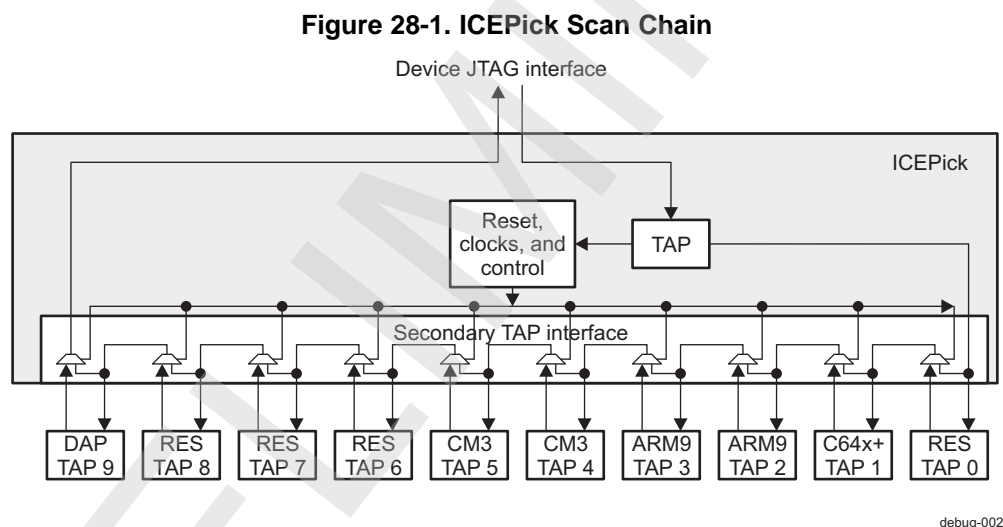

The device can boot to invoke WIR mode. If the device is booted in this mode, all processors within the device that support a TAP through ICEPick are held in reset until released. Individual processors may be released from reset (local), or all processors held in the reset state may be released at the same time (global).

## 28.3.3 Dynamic TAP Insertion

### 28.3.3.1 ICEPick Secondary TAPs

To include more or fewer secondary TAPs in the scan chain, the debugger must use the ICEPick TAP router to program the TAPs. At its root, ICEPick is a scan-path linker that lets the DTC selectively choose which subsystem TAPs are accessible through the device-level debug interface. Each secondary TAP can be dynamically included in or excluded from the scan path. From external JTAG interface point of view, secondary TAPs that are not selected appear not to exist.

Figure 28-1 shows the TAPs in the ICEPick scan chain.

**NOTE:** RES = Reserved/not used

CM3 = Cortex™-M3

DAP = Debug access port

Table 28-8 shows the secondary debug TAPs connected to the ICEPick scan chain along with the modules that can be accessed. The TAP number shows the position of the TAP in the scan chain.

**Table 28-8. ICEPick Secondary Debug TAP Mapping**

Secondary JTAG Port	CoreSight	TAP Number	Modules Accessed Through That JTAG Port
Reserved	No	0	–

## 28.4 Primary Debug Support

### 28.4.1 Processor Native Debug Support

#### 28.4.1.1 Cortex-A9 MPU

The dual Cortex-A9 processor supports the following native debug features:

- Halt mode and monitor mode debugging
- Six breakpoints and four watch points
- Asynchronous aborts
- Performance monitoring
- Cross-triggering: Allows stopping one CPU upon debug event (for example, breakpoint) detection in the other CPU

For more information about Cortex-A9 native debug support features, see the *Cortex-A9 Technical Reference Manual*.

#### 28.4.1.2 Cortex-M3 MPU

The Cortex-M3 processor supports the following native debug features:

- Program halt and stepping
- Hardware breakpoints, breakpoint instruction
- Data watch point on access to data add, add range, and data value
- Register value accesses
- Debug monitor exception
- Memories accesses

For more information about Cortex-M3 native debug support features, see the *Cortex-M3 Technical Reference Manual*.

#### 28.4.1.3 DSP

This information is not available in the public domain.

#### 28.4.1.4 IVA-HD ARM968

The ARM968E-S processor supports the following native debug features through its EmbeddedICE-RT logic:

- Two hardware watch points/breakpoints
- Halt mode and monitor mode debugging
- Debug control and status registers
- Debug communications channel

For more information about ARM968 native debug support features, see the *ARM968E-S Technical Reference Manual*.

#### 28.4.1.5 IVA-HD Hardware Accelerators

Hardware accelerators offer the following debug capabilities through their embedded SyncBox module:

- Manual halt: Halt occurs at the SyncBox task boundary, when requested by the debugger
- Single-step execution at SyncBox task level (from 1 to  $n$  macroblocks depending on the user software)
- Cross-triggering: Hardware accelerator can halt, after the execution of current SyncBox task, based on trigger event detection
- Global run

[Table 28-10](#) summarizes the debug capabilities of the hardware accelerator SyncBox.

**Table 28-10. Hardware Accelerator Debug Capability Options**

Feature	iME3	iPE3	MC3	CALC3	iLF3	ECD3
Core reset	-	-	-	-	-	-
Execution request	-	-	-	-	-	-
Trigger output	-	-	-	-	-	-
Trigger input	✓	✓	✓	✓	✓	✓
Number of trigger channels	1	1	1	1	1	1
Number of counters	0	0	0	0	0	0
Number of watch points	0	0	0	0	0	0
Number of hardware breakpoints	0	0	0	0	0	0

### 28.4.2 Cross-Triggering

The device supports a cross-triggering feature, which provides a way to propagate debug (trigger) events from one processor subsystem/module to another. For example, a given *subsystem A* can be programmed to generate a debug event, which can then be exported as a global trigger across the device. Another *subsystem B* can be programmed to be sensitive to the trigger line input and to generate an action upon trigger detection.

Examples of debug events are: processor entering debug state, watch point match, PTM trigger, ETB full, ETB acquisition complete, etc.

Examples of debug actions are: debug request generation, restart (Cortex-A9 synchronous run), interrupt request generation, start/stop trace, etc.

Subsystems cross-triggering is consolidated at the device level by the XTRIGGER module, which is embedded in the debug subsystem.

---

**NOTE:** XTRIGGER is not programmatically visible from the JTAG interface or any device processor. Thus, cross-triggering is programmed at the subsystem level.

---

### 28.4.2.1 SOC Level Cross-Triggering

Table 28-11 summarizes the device cross-triggering capabilities.

**Table 28-11. XTRIGGER**

Subsystem	Module		Cortex-A9	PTM/E TB	Cortex-M3	Cortex-M3	Target Core	IVA3- C64x	IVA-HD ARM96 8	IVA-HD ARM96 8	HWA	PM Instr	CM Instr	OCP- WP	EMU0/ EMU1

**NOTE:** The following modules support only trigger inputs:

- IVA-HD hardware accelerators
- IVA-HD SMSET
- PM instrumentation
- CM instrumentation

### 28.4.3 Suspend

The device supports a suspend feature, which provides a way to stop a "closely coupled" hardware process running on a peripheral-IP when the host processor enters debug state. The suspend mechanism is important for debug to ensure that peripheral-IPs operate in a lock-step manner with a host controller processor.

An entry is provided for each peripheral-IP that must consider the suspend signals from a number of processors (MPU or DSP). For each peripheral-IP, sensitivity to the suspend signals is defined within two possibilities (and so coded using 1bit):

- Peripheral-IP is sensitive to the suspend line request.
- Peripheral-IP ignores the suspend line request.

For more information about how to program the sensitivity, see the peripheral-IP TRM chapter.

#### 28.4.3.1 Debug Aware Peripherals and Host Processors

Table 28-12 lists the mapping of the device processors to the suspend control input lines.

**Table 28-12. Debug Subsystem Suspend Input Lines**

Suspend Input Line	Host Processor

## 28.5 Power, Reset, and Clock Management Debug Support

The global PRCM module implements facilities to support debug across power and clock domain cycles. The debugger can control or get the status of each power and clock domain associated with an ICEPick secondary TAP.

ICEPick provides a set of directives allowing the debugger to:

- Get visibility on the associated power and clock domains state. This includes:
  - Current power setting indicating whether the power domain is on or off
  - Loss of power detected since the software last checked the status
  - Current clock setting indicating whether the clock domain is on or off
  - Sleep desired (PM and CM indicate that the debug settings in ICEPick are changing the application state. If it were not for the ICEPick controls, the power or clock would be turned off.)
  - Subsystem reset state
  - Subsystem has entered a debug state that requires the attention of the host debug software.
- Override power/clock control settings to wake up a power or clock domain or to prevent a power or clock domain from going to sleep once it is in ACTIVE state
- Assert/block/extend reset; release from extended reset (WIR)

ICEPick handles debug power management at the device level. In addition, the OMAP4430 implements a second level of debug power management through the DAP-PC module integrated in the Cortex-A9 MPU subsystem, which provides the same capabilities as ICEPick for the two Cortex-A9 CPUs. Each Cortex-A9 CPU core is in its own independent power domain, which DAP-PC manages. The hierarchical debug power-management approach provided by DAP-PC at the subsystem level and by ICEPick at the device level ensures a theoretically independent debug capability for each Cortex-A9 CPU core.

---

**NOTE:** The debugger must properly sequence global ICEPick and local DAP-PC commands:

- To force clocks/power:
    1. The debugger must first force it for the Cortex-A9 MPU subsystem at the ICEPick level.
    2. The debugger must then force it for a specific Cortex-A9 CPU at the DAP-PC level.
  - To release clocks/power:
    1. The debugger must first release it for a specific Cortex-A9 CPU at the DAP-PC level.
    2. The debugger must then release the Cortex-A9 MPU subsystem controls at the ICEPick level.
-

## 28.6 Performance Monitoring

### 28.6.1 Cortex-A9 MPU Subsystem Performance Monitoring

#### 28.6.1.1 Performance Monitoring Unit

The Cortex-A9 processor includes a performance monitoring unit (PMU) that enables events, such as cache misses and instructions executed, to be counted over a period of time. The PMU provides six counters to gather statistics about the operation of the processor and memory system. Each counter can count any of the events available in Cortex-A9.

The Cortex-A9 PMU outputs 29 events (PMUEVENT[28:0]) to PTM (see [Table 28-14](#)).

**Table 28-14. PMU Events**

PMU Event	Description
0	Software increment
1	Instruction fetch that causes a refill
2	Instruction fetch that causes a TLB refill
3	Data read or write operation that causes a refill
4	Data read or write operation that causes a cache access
5	Data read or write operation that causes a TLB refill
6	Data read architecturally executed
7	Data write architecturally executed
8	Number of instructions decoded
9	Exception taken
10	Exception return architecturally executed
11	Change to context ID retired
12	Software change of PC
13	Immediate branch architecturally executed
14	Number of predictable function returns
15	Unaligned access architecturally executed
16	Branch mispredicted or not predicted
17	Branches or other change in program flow
18	Java byte code executed
19	Software Java byte code executed
20	Jazelle backward branches executed
21	Coherent line fill request that misses in other uniprocessors
22	Request for coherent line fill that hits in other uniprocessors
23	Instruction cache dependent stalls
24	Data cache dependent stalls
25	TLB miss dependent stalls
26	STREX passed
27	STREX failed
28	Data eviction

For more information about Cortex-A9 PMU, see the *ARM Cortex-A9 Technical Reference Manual*.

#### 28.6.1.2 Snoop Control Unit

The individual CPU event monitors can be configured to gather statistics about the operation of the snoop control unit (SCU).

### 28.6.1.3 L2 Cache (PL310)

The Cortex-A9 MPU subsystem includes 512KB of L2 cache and uses PL310 as the L2 cache controller. The PL310 includes logic to support cache event monitoring.

Table 28-15 summarizes the PL310 L2 cache events.

**Table 28-15. PL310 L2 Cache Events**

Event	Event Description
0	Eviction of a line from the L2 cache
1	Data read hit in the L2 cache
2	Data read lookup to the L2 cache. Subsequently results in a hit or miss.
3	Data write hit in the L2 cache
4	Data write lookup to the L2 cache. Subsequently results in a hit or miss.
5	Data write lookup to the L2 cache with Write-Through attribute. Subsequently results in a hit or miss.
6	Instruction read hit in the L2 cache
7	Instruction read lookup to the L2 cache. Subsequently results in a hit or miss.
8	Prefetch line-fill sent to L3
9	Allocation into the L2 cache caused by a write (with Write-Allocate attribute) miss

The PL310 implements two 32-bit event counters. The PL310 can be configured to generate interrupts on error conditions or event counter overflow or increment. The PL310 interrupt is routed to MA\_IRQ\_0. When an interrupt occurs, software can look at the relevant interrupt status register to determine the source of the interrupt.

For more information about PL310, see the ARM *PrimeCell Level 2 Cache Controller (PL310) Technical Reference Manual*.

## 28.6.2 Cortex-M3 MPU Subsystem Performance Monitoring

### 28.6.2.1 Subsystem Counter Timer Module

The dual Cortex-M3 MPU subsystem includes a subsystem counter timer module (SCTM), which is embedded in shared cache and provides additional data to the user timing or profiling capability. SCTM integrates eight profiling counters that collect:

- Shared cache events
- Sleep and deep sleep events from each Cortex-M3

Table 28-16 describes the configuration of the Cortex-M3 SCTM counters.

**Table 28-16. Cortex-M3 SCTM Counters Configuration**

Counters	Features
0 – 1	Timer and event
2 – 3	64-bit chained + shadowing
4 – 5	64-bit chained + shadowing
6 – 7	Event

### 28.6.2.2 Cache Events

Table 28-17 summarizes the SCTM events for the Cortex-M3 MPU subsystem.

**Table 28-17. SCTM Events For Cortex-M3 MPU Subsystem**

Event	Event Description
0	Cache hit
1	Nonregistered tag hit information

**Table 28-17. SCTM Events For Cortex-M3 MPU Subsystem (continued)**

Event	Event Description
2	Cache miss
3	Read event
4	Write event
5	Fill buffer hit
6	Write buffer hit
7	Allocation ongoing
8	Bank miss
9	Stall due to busy ocp
10	Stall due to maintenance
11	Line evicted
12	Line replaced
13	Allocation failed due to locked lines

**NOTE:** These cache metrics can be exported as STP software messages through STM.

### 28.6.3 DSP Subsystem Performance Monitoring

#### 28.6.3.1 Subsystem Counter Timer Module

The DSP subsystem includes an SCTM, which is embedded in the DSP megamodule and provides additional data to the user timing or profiling capability. SCTM integrates eight profiling counters that collect L1 and L2 events.

[Table 28-16](#) describes the configuration of the DSP SCTM counters.

**Table 28-18. DSP SCTM Counters Configuration**

Counters	Features
0 – 1	Timer and event
2 – 7	Event (no chaining)

#### 28.6.3.2 L1 and L2 Events

[Table 28-19](#) summarizes the SCTM events for DSP subsystem.

**Table 28-19. SCTM Events For DSP Subsystem**

Event	Event Description
0	L1 Slave0 (program) tag hit
1	L1 Slave1(data) tag hit
2	L1 Slave0 (program) tag miss
3	L1 Slave1(data) tag miss
4	L1 Slave0 (program) fill buffer hit
5	L1 Slave1(data) fill buffer hit
6	L1 Slave1(data) write buffer hit
7	L1 Allocation FIFO
8	L1 Slave0 (program) bank conflict
9	L1 Slave1(data) bank conflict
10	L1 Slave0 (program) cached request
11	L1 Slave1(data) cached request
12	L1 Slave0 (program) waiting for fill buffer

**Table 28-19. SCTM Events For DSP Subsystem (continued)**

<b>Event</b>	<b>Event Description</b>
13	L1 Slave1(data) waiting for fill buffer
14	L1 Slave0 (program) waiting for maintenance
15	L1 Slave1(data) waiting for maintenance
16	L1 Eviction occurred
17	L1 Replacement occurred
18	L1 Allocation failed due to locked lines occurred
19	L2 tag hit
20	L2 tag miss
21	L2 fill buffer hit
22	L2 write buffer hit
23	L2 allocation FIFO
24	L2 cached request
25	L2 waiting for fill buffer
26	L2 waiting for maintenance
27	L2 eviction occurred
28	L2 replacement occurred
29	L2 allocation failed due to locked lines occurred

---

**NOTE:** These cache metrics can be exported as STP software messages through STM.

---

## 28.7 Processor Trace

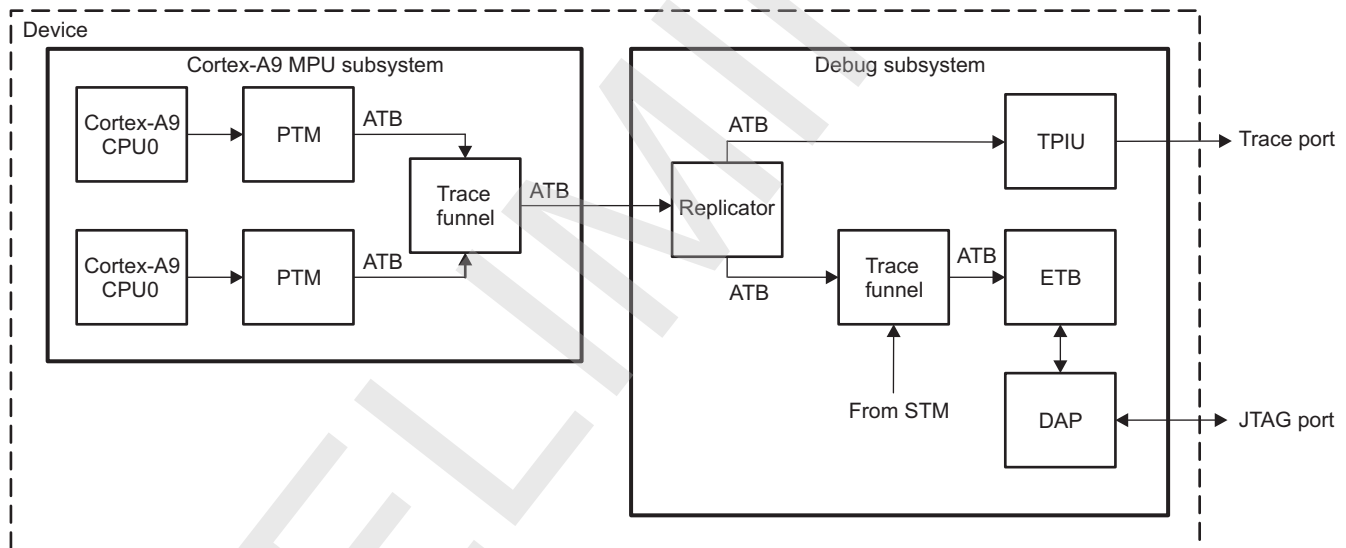

The device supports only Cortex-A9 processor trace. The main Cortex-A9 processor trace characteristics are:

- Program trace only (no data trace)
- Separate PTM for each Cortex-A9 CPU
- Trace can be:
  - Exported off-chip through TPIU in the debug subsystem (maximum number of trace data pins = 18)
  - Stored on-chip to ETB through CS-TF in the debug subsystem
- Trace can be optionally:
  - Cycle accurate useful for profiling sections of code
  - Interleaved dynamically between the two Cortex-A9 CPUs by a CS-TF embedded in the Cortex-A9 MPU subsystem

**NOTE:** Depending on use case, the device may not be able to interleave two cycle accurate traces without overflow (bandwidth restriction).

Figure 28-2 shows an overview of the processor trace flow.

**Figure 28-2. Processor Trace Flow**

debug-004

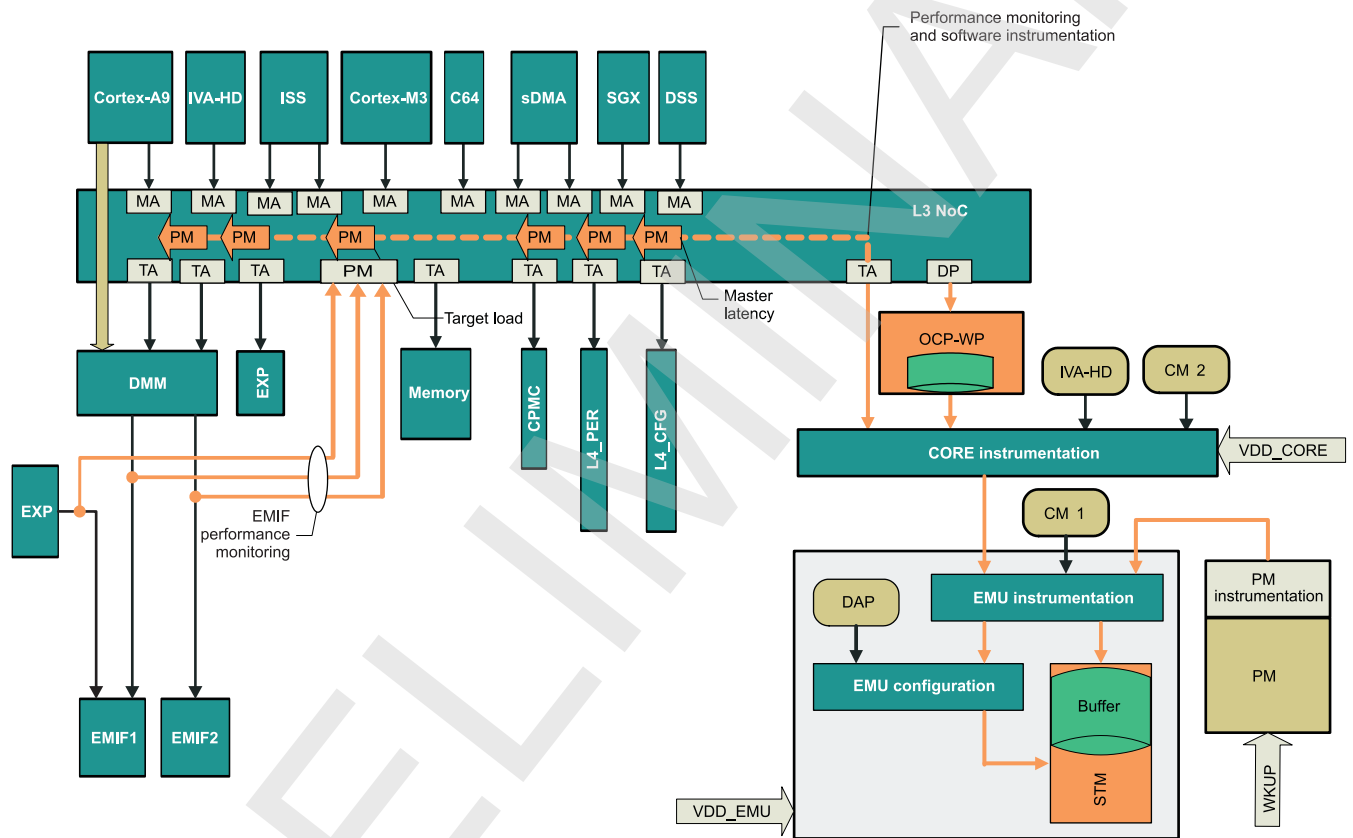

## 28.8 System Instrumentation

The device supports the following system instrumentation features:

- Real-time software trace (see [Section 28.8.2, Software Instrumentation](#))
- OCP target traffic monitoring (see [Section 28.8.3, OCP Watch-Point](#))
- OCP target load and master latency monitoring (see [Section 28.8.5, NoC Statistics Collector](#))
- HWA load monitoring (see [Section 28.8.4, IVA-HD Pipeline](#))
- PM events trace (see [Section 28.8.6, PM Instrumentation](#))
- CM events trace (see [Section 28.8.7, CM Instrumentation](#))

Figure 28-3 is an overview of the device system instrumentation framework.

Figure 28-3. System Instrumentation Framework

debug-005

### 28.8.1 MIPI STM

MIPI-STM is a trace module that aids in software debugging. The main features of this module are:

- Implements MIPI STP protocol (rev 1.0) with the following characteristics:
  - Highly optimized for software-generated traces
  - Automatic timestamping of messages
  - Support for 8-, 16-, and 32-bit data types
- Collects the following information:
  - Software messages
  - Hardware instrumentation trace from hardware agents:
    - OCP-WP
    - PM profiler
    - CM profiler

- SMSET
- L3 NoC statistics collectors
- Exports trace data to:
  - External trace receiver
  - On-chip ETB buffer
- Available in 1-, 2-, or 4-pin mode with single- or dual-edge clock, depending on the trace bandwidth requirements and characteristics of the trace receiver
- Dedicated 128 × 32-bit FIFO buffer

A maximum of 255 different bus masters can be connected to the STM trace port through a bus arbiter. STP recognizes two distinct modes of tracing (software and hardware types), which use slightly different message combinations to output different types of data. The bus masters can be configured for either type to optimize the system for the different types of trace data.

### 28.8.2 Software Instrumentation

The device provides support for real-time software trace through user-defined message writes to specific memory mapped register (MMR) locations. Software masters can transmit trace data from the operating system (OS) processes or tasks on 256 different channels, with each channel being defined by the software protocol implemented. The different channels can be used to group different types of data logically so that it is easy to filter out the data irrelevant to the on-going debugging task. The message structures in STP are optimized to provide an efficient transport for software data through the STM module.

The software masters are:

- Cortex-A9 MPU subsystem
- DAP (for testing purpose)
- DSP subsystem
- Dual Cortex-M3 MPU subsystem
- sDMA controller write port (SDMA\_WR)
- IVA-HD subsystem

Each software master has a master-ID assigned to it.

Software messages can be interleaved with other hardware messages.

Software messages are intrusive and use both processor cycles and memory.

### 28.8.3 OCP Watch-Point

The L3 interconnect provides five functional probes embedded and attached to the following L3 targets:

- GPMC
- L4-PER
- L4-CFG
- DMM1 (DMM target port 1)
- DMM2 (DMM target port 2)

The probes output are muxed together and then sent to the L3 interconnect debug port. A component called OCP-WP is used to collect data from functional probes and then transmit captured data to the STM module. The OCP-WP drives a Probe-ID signal to the L3 interconnect for probe selection. The probe selection is exclusive, meaning that interleaving is not possible.

The OCP-WP provides the following main features:

- Monitoring the OCP traffic originated by all initiators that can access the selected target where the probe is attached
- Filtering OCP monitored bus traffic by:
  - Address range
  - Initiator-ID (see [Section 13.2, L3 Interconnect](#), for initiator-ID mapping)

- Transaction type
- Transaction qualifier
- Generating a trigger upon watch-point match
- Starting and stopping OCP traffic monitoring upon:
  - WP address match
  - External trigger
- OCP-WP messages can be interleaved with software messages
- Programming from:
  - Debugger
  - Application

**NOTE:** The OCP-WP is restricted to monitor request flow.

Table 28-20 summarizes the OCP targets that can be monitored by the OCP-WP and their respective probe-ID.

**Table 28-20. L3 Interconnect Functional Probe Mapping**

Probe-ID	L3 OCP Target
000	Reserved
001	GPMC
010	L4-PER
011	L4-CFG
100	DMM1 (DMM target port 1)
101	DMM2 (DMM target port 2)
110	Reserved
111	Reserved

### 28.8.4 IVA-HD Pipeline

The device takes advantage of the system trace infrastructure to provide visibility to the user regarding IVA-HD micro-task sequencing. This is supported through a SMSET module instantiated in the IVA-HD subsystem. The micro-task boundaries are handled as generic events and encapsulated in STP messages with an event-ID and local timestamp and exported through the MIPI-STM module.

The IVA-HD instrumentation scheme allows the user to understand micro-task dependencies, hardware accelerators load balancing, and potential bottlenecks. DMA transfer boundaries are reported as IVA-HD events. Software messages from ARM968 execution can be interleaved with IVA-HD events.

### 28.8.5 NoC Statistics Collector

The L3 interconnect supports a built-in performance monitoring feature by implementing a statistics collector (STATCOLL) component, which computes traffic statistics within a user-defined window and periodically reports to the user through the MIPI-STM interface. Three STATCOLL instances are instantiated in the device:

- One statistics collector dedicated to SDRAM load monitoring – STATCOLL\_SDRAM (see [Section 28.8.5.1, OCP Target Load Monitoring](#), for more information)
- Two statistics collectors dedicated to master latency monitoring – STATCOLL\_LAT0 and STATCOLL\_LAT1 (see [Section 28.8.5.2, OCP Master Latency Monitoring](#), for more information)

Statistics collectors (SDRAM and LAT0/1) can report:

- Average burst length in bytes/packet per sampling window
- Average throughput in bytes/cycle
- % Link occupancy on the request link (for store transactions) during a sampling window
- % Link occupancy on the response link (for load transactions) during a sampling window

- % Arbitration conflict cycles on the request link
- % Initiator busy cycles on the response link
- Histogram of payload length in bytes (for example, 0–16 , 16–32, 32–128) each sampling window.
- Histogram of quality of service (QoS) metric for IVA-HD initiator (for example, low priority, high priority) each sampling window.

The performance metrics are interleaved with software instrumentation data at the L3 interconnect level.

The performance monitoring probes implement three main functions:

- Events detection
- Transactions filtering
- Aggregation

The probes can be configured to detect the events summarized in [Table 28-21](#).

**Table 28-21. Performance Monitoring Events Detection**

Event	Definition
NONE	No event selected
ANY	Any clock cycles
TRANSFER	Word has been accepted by the receiver.
WAIT	Transfer has been initiated but the transmitter currently has no data to send.
BUSY	Receiver applies flow control
PKT	Transfer of a new packet header
DATA	Transfer of a payload word
IDLES	No communication over the link
LATENCY	Debug bit detection

The probes can be configured to filter the traffic based on the criteria summarized in [Table 28-22](#).

**Table 28-22. Performance Filtering Options**

Probe Filtering Options	Comment
Master address	Mask and match
Slave address	
UserInfo	
Read	Opcode is a load.
Write	Opcode is a store.
Error	–

The probes implement a user-defined set of counters that aggregate the events sampled by the detector and filtered according to the user setup.

**NOTE:** Statistics collectors counter values are not accessible by application software.

[Table 28-23](#) summarizes the performance probe aggregation modes.

**Table 28-23. Aggregation Modes**

Aggregation Mode	Description
FILTER_HIT	The counter increments by 1 when the filter hits.
MIN_MAX_HIT	The counter increments by 1 when the filter hits and the selected event information is within range. <ul style="list-style-type: none"> <li>- Payload length (bytes)</li> <li>- Pressure value</li> <li>- Request/response latency (clock cycles)</li> </ul>
EVT_INFO	The selected event information is added to the counter value when the filter hits.

**Table 28-23. Aggregation Modes (continued)**

Aggregation Mode	Description
	Payload length (bytes) Pressure value Request/response latency (clock cycles)
AND_FILTER	The counter increments by 1 when all unit filters hit.
OR_FILTER	The counter increments by 1 when at least one unit filter hits.
SUM_REQ_EVT	The counter sums the events from any request port.
SUM_RSP_EVT	The counter sums the events from any response port.
SUM_ALL_EVT	The counter sums the events from any port.
EXT_EVT	The counter increments by 1 when selected external event input signal is sampled high.

### 28.8.5.1 OCP Target Load Monitoring

The L3 interconnect implements three performance monitoring probes on LPDDR2 memory channels. The OCP traffic statistics are computed within a user-defined window and periodically reported to the user through the MIPI-STM interface.

STATCOLL\_SDRAM supports the following main features:

- Three probe inputs
  - Probe 0 – EMIF1 128-bit memory channel
  - Probe 1 – EMIF2 128-bit memory channel
  - Probe 2 – EMIF 64-bit EXP interface – allows monitoring traffic from C2C (shared memory)
- Five 16-bit counters shared concurrently
  - Counter 0 with two filters
  - Counter 1 with one filter
  - Counter 2 with two filters
  - Counter 3 with one filter
  - Counter 4 without any filter
- Simple (with one element) or complex (with several elements) filters available
- Filtering according to:
  - Initiator of traffic
  - Access priorities
- No latency counter. Only bandwidth measurement on this collector
- Dump Identifier is 0x0 (tie-off value)
- Dumps frames at L3 interconnect slave address 0x19 (debug subsystem)

Table 28-24 summarizes the STATCOLL\_SDRAM configuration.

**Table 28-24. STATCOLL\_SDRAM Configuration**

Counters	Min Max	Filter Elements	L3 Target		
			EMIF1	EMIF2	EXP
Counter 0	Yes	2	EMIF1	EMIF2	EXP
Counter 1	Yes	1	EMIF1	EMIF2	EXP
Counter 2	Yes	2	EMIF1	EMIF2	EXP
Counter 3	Yes	1	EMIF1	EMIF2	EXP
Counter 4	Yes	No	No	No	EXP

### 28.8.5.2 OCP Master Latency Monitoring

The device L3 interconnect implements nine performance monitoring probes on the main L3 initiators:

- Cortex-A9 MPU Subsystem

- DSP
- sDMA controller read port (SDMA\_RD)
- sDMA controller write port (SDMA\_WR)
- IVA-HD
- DSS
- ISS
- SGX
- Dual Cortex-M3 MPU subsystem

The OCP master latency statistics are computed within a user-defined window and periodically reported to the user through the MIPI-STM interface.

The probes can be configured to filter latencies in four classes and report to the user a latency distribution along execution.

Because the performance metrics and the software events are exported through a unified export channel, it is possible to correlate latency trends with on-going execution and system context.

Because computing latency requires maintaining the state between request and response ports, the probe cannot compute latency statistics on 100 percent of the initiator traffic. Hence, latency histograms must be extracted on large execution windows to be accurate.

#### 28.8.5.2.1 STATCOLL\_LAT0 Configuration

STATCOLL\_LAT0 supports the following main features:

- Six probe inputs:
  - Probe 0: Cortex-A9 MPU subsystem
  - Probe 1: DSP subsystem
  - Probe 2: sDMA controller RD port
  - Probe 3: sDMA controller WR port
  - Probe 4: DSS
  - Probe 5: ISS
- Four 20-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 10-bit counter for latency measurement
- Identifier is 0x1 (tie-off value)
- Dumps frames at slave address 0x19 (DEBUGSS)

[Table 28-25](#) summarizes the STATCOLL\_LAT0 configuration.

**Table 28-25. STATCOLL\_LAT0 Configuration**

Counters	Min Max	Filter Elements	L3 Master					
			Cortex-A9 MPU subsystem	DSP	sDMA read	sDMA write	DSS	ISS
Counter 0	Yes	1	Cortex-A9 MPU subsystem	DSP	sDMA read	sDMA write	DSS	ISS
Counter 1	Yes	1	Cortex-A9 MPU subsystem	DSP	sDMA read	sDMA write	DSS	ISS
Counter 2	Yes	1	Cortex-A9 MPU subsystem	DSP	sDMA read	sDMA write	DSS	ISS

**Table 28-25. STATCOLL\_LAT0 Configuration (continued)**

Counter 3	Yes	1	Cortex-A9 MPU subsystem	DSP	sDMA read	sDMA write	DSS	ISS
-----------	-----	---	-------------------------	-----	-----------	------------	-----	-----

### 28.8.5.2.2 STATCOLL\_LAT1 Configuration

STATCOLL\_LAT1 supports the following main features:

- Five probe inputs:
  - Probe 0: IVA-HD
  - Probe 1: Cortex-A9 MPU subsystem
  - Probe 2: sDMA controller WR port
  - Probe 3: SGX
  - Probe 4: Dual Cortex-M3 MPU subsystem
- Four 20-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 10-bit counter for latency measurement
- Identifier is 0x2 (tie-off value)
- Dumps frames at slave address 0x19 (DEBUGSS)

Table 28-26 summarizes the STATCOLL\_LAT1 configuration.

**Table 28-26. STATCOLL\_LAT1 Configuration**

Counters	Min Max	Filter Elements	L3 Master				
			IVA-HD	Cortex-A9 MPU subsystem	sDMA write	SGX	Dual Cortex-M3 MPU subsystem
Counter 0	Yes	1	IVA-HD	Cortex-A9 MPU subsystem	sDMA write	SGX	Dual Cortex-M3 MPU subsystem
Counter 1	Yes	1	IVA-HD	Cortex-A9 MPU subsystem	sDMA write	SGX	Dual Cortex-M3 MPU subsystem
Counter 2	Yes	1	IVA-HD	Cortex-A9 MPU subsystem	sDMA write	SGX	Dual Cortex-M3 MPU subsystem
Counter 3	Yes	1	IVA-HD	Cortex-A9 MPU subsystem	sDMA write	SGX	Dual Cortex-M3 MPU subsystem

### 28.8.6 PM Instrumentation

The device takes advantage of the system trace infrastructure to provide visibility to the user about the major power management events. This is supported through a PM profiler module instantiated in the PRM module. The PRM state changes are handled as generic events and encapsulated in STP hardware messages and exported through the MIPI-STM module. The nature of the PM events does not require accurate timestamping and thus, timestamping is handled at STM or trace receiver level.

The PM events are organized by class. Any PM state change from a specific class refreshes the entire instrumentation frame associated with that class. The STP message structure includes a PM event-ID indicating the class of the PM events.

The PM event classes supported are:

- Logic voltage domain OPP change
- Memory voltage domain OPP change
- Logic power domain state change

- Memory power domain state change

The PM profiler has a unique hardware master-ID assigned to it.

The PM profiler supports the possibility to report on activity in different event classes in the same sampling window. The user has the flexibility to size the capture sampling window.

Software events from the PM routines instrumentation can be interleaved with the PM hardware events. The user can take advantage of that feature to understand latencies for a specific power-management scenario or strategy.

### 28.8.7 CM Instrumentation

The device instantiates two CM profilers, one in CM1, and one in CM2. The CM1 and CM2 profilers are instantiations of the same debug-IP and can operate concurrently. Each of them has a separate unique hardware master-ID assigned to it.

The CM events profiling is similar to the PM instrumentation. Two exclusive instrumentation modes are supported:

- Clock activity:
  - Exposes to the user a snapshot of the state of all the clock domains derived from the same DPLL when CM detects a state change in the clock domain
  - Exposes to the user a snapshot of the DPLL settings when the CM signals a DPLL programming
- Module activity:
  - Exposes to the user periodically the active cycles count of the target modules
  - Exposes to the user periodically the active cycles count of the initiator modules

It provides visibility to the user about the state of the major clock domains along the application code execution. The STP message reports the effective state of the clock domain and therefore can highlight scenarios where a particular dependency is preventing the clock domain from being switched off.

The CM event classes supported are:

- Events capture mode – four classes:
  - Clock domain state
  - DPLL settings update
  - Clock frequency divider ratio
  - Clock source selection update
- Module activity collection mode – two classes:
  - Target module activity
  - Initiator module activity

When in events capture mode, the CM profiler supports the possibility of reporting on activity in different event classes in the same sampling window. The user has the flexibility to size the capture sampling window.

## 28.9 Concurrent Debug Modes

The debugger or application software can program the DRM to route a specific debug function to each device debug port pin.

Because of the limited number of pins allocated to debug, debug and trace source signals are multiplexed.

[Table 28-27](#) summarizes the trace port configuration.

**Table 28-27. Trace Port Configuration**

Pin Name	Internal Signal Name	I/O	Trigger	JTAG 20-Pin Header	TPIU PTM (ARM Trace)		STM (System Trace)		
					16-Bit Mode	18-Bit Mode	Option 1	Option 2	Option 3
dpm_emu19	EMU19	O		EMU4	TRACEDATA[15]	TRACEDATA[17]		STM_CLK	
dpm_emu18	EMU18	O		EMU3	TRACEDATA[14]	TRACEDATA[16]		STM_DATA[0]	
dpm_emu17	EMU17	O		EMU2	TRACEDATA[13]	TRACEDATA[15]		STM_DATA[1]	
dpm_emu16	EMU16	O			TRACEDATA[12]	TRACEDATA[14]		STM_DATA[2]	
dpm_emu15	EMU15	O			TRACEDATA[11]	TRACEDATA[13]		STM_DATA[3]	
dpm_emu14	EMU14	O			TRACEDATA[10]	TRACEDATA[12]		UART1_RX	
dpm_emu13	EMU13	O			TRACEDATA[9]	TRACEDATA[11]			
dpm_emu12	EMU12	O			TRACEDATA[8]	TRACEDATA[10]			
dpm_emu11	EMU11	O			TRACEDATA[7]	TRACEDATA[9]			
dpm_emu10	EMU10	O			TRACEDATA[6]	TRACEDATA[8]			
dpm_emu9	EMU9	O			TRACEDATA[5]	TRACEDATA[7]			
dpm_emu8	EMU8	O			TRACEDATA[4]	TRACEDATA[6]			
dpm_emu7	EMU7	O			TRACEDATA[3]	TRACEDATA[5]			
dpm_emu6	EMU6	O			TRACEDATA[2]	TRACEDATA[4]			
dpm_emu5	EMU5	O			TRACEDATA[1]	TRACEDATA[3]			
dpm_emu4	EMU4	O			TRACEDATA[0]	TRACEDATA[2]	STM_DATA[3]		
dpm_emu3	EMU3	O			TRACECTL	TRACECTL	STM_DATA[2]		
dpm_emu2	EMU2	O			TRACECLK	TRACECLK	STM_CLK		
dpm_emu1	EMU1	I/O	Trigger 1	EMU1		TRACEDATA[1]	STM_DATA[1]		STM_CLK
dpm_emu0	EMU0	I/O	Trigger 0	EMU0		TRACEDATA[0]	STM_DATA[0]		STM_DATA[0]

**NOTE:** The configuration of the trace port must comply with [Table 28-27](#); otherwise, it will be ignored by DRM hardware. For example, if Trigger0 is programmed on EMU10 and Trigger1 is programmed on EMU11, this configuration will be ignored.

[Table 28-28](#) summarizes the concurrent debug and trace in the device.

**Table 28-28. Concurrent Debug and Trace**

Debug Use Case	Concurrent Debug Flows	Debug Pins	Trace Pins		
		Triggers	Data	Control	Clock
0	PTM		18	1	1
	STM				
	Triggers				
1	PTM		16	1	1
	STM				
	Triggers	2			
2	PTM		16	1	1
	STM		1	–	1
	Triggers				
3	PTM		8	1	1
	STM		4	–	1
	Triggers	2			
4	PTM		11	1	1
	STM		4	–	1
	Triggers	2			

## 28.10 Memory Mapping

Table 28-29 summarizes the memory mapping of the debug modules.

**Table 28-29. Debug Modules Memory Mapping**

Memory Space	Module Name	Start Address (hex)	End Address (hex)	Size
L3_EMU	MIPI-STM (256 x 4K channels) (address space 0)	0x5400 0000	0x540F FFFF	1MB
	MIPI-STM (256 x 1K channels) (address space 1)	0x5410 0000	0x5413 FFFF	256KB
	Cortex-A9 CPU0 debug/PMU	0x5414 0000	0x5414 1FFF	8KB
	Cortex-A9 CPU1 debug/PMU	0x5414 2000	0x5414 3FFF	8KB
	CTI0 component	0x5414 8000	0x5414 8FFF	4KB
	CTI1 component	0x5414 9000	0x5414 9FFF	4KB
	PTM0 component	0x5414 C000	0x5414 CFFF	4KB
	PTM1 component	0x5414 D000	0x5414 DFFF	4KB
	CS-TF <sup>(1)</sup>	0x5415 8000	0x5415 8FFF	4KB
	DAP-PC	0x5415 9000	0x5415 9FFF	4KB
	DRM	0x5416 0000	0x5416 0FFF	4KB
	MIPI-STM	0x5416 1000	0x5416 1FFF	4KB
	CS-ETB	0x5416 2000	0x5416 2FFF	4KB
	CS-TPIU	0x5416 3000	0x5416 3FFF	4KB
	CS-TF <sup>(2)</sup>	0x5416 4000	0x5416 4FFF	4KB
L4_CFG	PMI-CM1	0x4A00 4F00	0x4A00 4FFF	256B
	PMI-CM2	0x4A00 9F00	0x4A00 9FFF	256B
	OCF-WP	0x4A10 2000	0x4A10 2FFF	4KB
L4_WKUP	PMI-PM	0x4A30 7F00	0x4A30 7FFF	256B
IVA-HD configuration	ICECrusher-9 (ICONT1)	0x5A04 0000	0x5A04 07FF	2KB
	ICECrusher-9 (ICONT2)	0x5A04 0800	0x5A04 0FFF	2KB
	SMSET	0x5A04 1000	0x5A04 1FFF	4KB
L3 configuration	STATCOLL_SDRAM	0x4500 0400	0x4500 05FF	512B
	STATCOLL_LAT0	0x4500 0600	0x4500 07FF	512B
	STATCOLL_LAT1	0x4500 0800	0x4500 09FF	512B
DSP configuration	SCTM	0x01C3 0400	0x01C3 05FF	512B
Cortex-M3 MPU subsystem configuration	SCTM	0x5508 0400	0x5508 07FF	1KB
	ICECrusher-CS x 2 <sup>(3)</sup>	0xE004 2000	0xE004 2FFF	4KB

(1) Embedded in Cortex-A9 MPU subsystem

(2) Embedded in debug subsystem

(3) Private memory access per Cortex-M3 core

---

## Glossary

---

**3**

- 3D**— Three Dimensional  
**3G**— 3rd Generation of mobile communication systems

**A**

- A/D**— Analog to Digital Converter  
**ABB**— Adaptive Body Bias  
**ABE**— Audio Back End  
**ABEFW**— Audio Back End Firewall  
**ACB**— ac-bias frequency  
**ACBI**— ac-bias line transitions per interrupt  
**ACE**— ASIC Compiler Environment.  
**ACK**— Acknowledge  
**ADC**— Analog-to-Digital Converter/Conversion.  
**ADMA**— Audio DMA  
**ADPLL**— All Digital Phase Locked Loop. A closed loop frequency control system whose function is based on the phase-sensitive detection of the phase difference between the input signal and the output signal of the controlled oscillator (CO).  
**AE**— Audio Engine. The AESS own processor.  
**AES**— Advanced Encryption Standard  
**AESS**— Audio Engine Subsystem  
**AEW**— Auto Exposure and Auto White Balance  
**AF**— Auto Focus  
**AFE**— Analog Front End  
**AHB**— Advanced High-performance Bus  
**ALE**— Address Latch Enable  
**AMMU**— Attribute Memory Management Unit  
**ANSI**— American National Standards Institute  
**AP**— Address Protection  
**APB**— Advanced Peripheral Bus

**APE**— Application Engine

**API**— Application Programming Interface

**AR**— Automatic Reload

**ARGB**— Alpha Red Green Blue

**ARM**— Advanced RISC Machine

**ASCII**— American Standard Code for Information Interchange

**ASIC**— Application-Specific Integrated Circuit. A chip built for a particular application. In the context of this document, this refers to the FPGA that resides on the EVM board.

**ASP**— Application-Specific Peripheral

**ATA**— Interface standard for the connection of storage devices

**ATB**— AMBA Advanced Trace Bus

**ATC**— Audio Traffic Controller

**AVDAC**— Audio-Video DAC

**AVS**— Adaptive Voltage Scaling

**AWB**— Auto White Balance

**B**

**B**— Byte, 8 bits

**BAYER**— Bayer Filter mosaic. A color filter array (CFA) for arranging RGB color filters on a square grid of photosensors.

**BB**— Bus Busy

**BCD**— Binary-Coded Decimal.

**BCH**— Bose-Chaudhuri-Hocquenghem

**BE**— Big Endian.

**BGA**— Ball Grid Array

**BGAP**— Band Gap

**BIOS**— Built-In Operating System

**BIST**— Built-In Self-Test

**BL**— Buffer Logic

**BOF**— Beginning of Frame

**BPP**— Bits Per Pixel

**BS**— Block Synchronization

**BSC**— Boundary Scan Chain

**BSMEM**— Bit Stream Memory

**BTA**— Bus Turn Around

**BTE**— Burst Translation Engine

**BW**— Band Width

**Bluetooth**— A short-range radio technology aimed at simplifying communications among network devices and between devices and the Internet. It also aims to simplify data synchronization between network devices and other computers.

## C

**C2C**— Chip-to-Chip

**CABAC**— Context-Adaptive Binary Arithmetic Coding

**CALC3**— Transform and Quantization Calculation Engine

**CAS**— Column Address Strobe

**CAVLC**— Context-Adaptive Variable Length Coder

**CB**— Copy Back

**CBP**— Coded Block Pattern

**CBUFF**— Circular Buffer

**CCCR**— Card Common Control Registers (SDIO)

**CCP**— Compact Camera Port

**CDP**— Coprocessor Data Operation

**CDR**— Clock Data Recovery

**CE**— Chip Enable

**CEA-861-D**— HDMI 1.3 video standard. It defines the video timing requirements, discovery structures, and data transfer structure.

**CEC**— Consumer Electronics Control

**CFA**— Color Filter Array

**CH**— Configuration Header. To use different settings than ROM Code defaults, that is, clock frequencies, SDRAM/DDRAM settings, GPMC settings if the customer wants.

**CID**— Card Identification Number

**CIR**— Consumer Infra Red

**CLE**— Command Latch Enable

**CLK**— Clock

**CLUT**— Color Look-Up Table

**CM**— Clock Management

**CMEM**— Coefficient Memory

**CMOS**— Complimentary Metal Oxide Semiconductor

**CODEC**— Coder/Decoder or Compression/Decompression. A device that codes in one direction of transmission and decodes in another direction of transmission.

**CP15**— Coprocessor 15. This coprocessor controls the operation and configuration of the TI925T.

**CPR**— Clock, Power, Reset

- CPU**— Central Processing Unit.
- CRC**— Cyclic Redundancy Check
- CS**— Chip-Select
- CS-ETB**— CoreSight Embedded Trace Buffer
- CS-ETM**— CoreSight Embedded Trace Macrocell
- CS-TPIU**— CoreSight Trace Port Interface Unit
- CSI**— Camera Serial Interface
- CSW**— Control Space Width
- CSWR**— Closed switch retention
- CTM**— Counter-Timer Module
- CTRL**— Control
- CTS**— Clear to Send
- CVBS**— Composite Video Broadcast Signal
- ConnID**— Connection Identifier. An Initiator Module Identifier. A ConnID is transmitted in-band with the request and is used for protection and error logging mechanism.

**D**

- D2D**— Die-to-Die
- DAC**— Digital to Analog Converter
- DBB**— Digital Baseband
- DBI**— Display Buffer Interface
- DCD**— Data Carrier Detect
- DCO**— Digitally Controlled Oscillator
- DCS**— Display Command Set
- DCT**— Discrete Cosine Transform.
- DDC**— Display Data Channel
- DDMA**— DSP Subsystem Direct Memory Access module
- DDR**— Double Data Rate
- DE**— Data Enable
- DFF**— Digital Flip-Flop
- DFT**— Design For Test
- DI**— Data In
- DISPC**— Display Controller
- DL**— Data Length
- DLB**— Data Loopback.
- DLL**— Delay-Locked Loop

- DMA**— Direct Memory Access.
- DMC**— Data Memory Controller
- DMEM**— Data Memory
- DMIC**— Digital Microphone Controller
- DMM**— Dynamic Memory Management
- DNL**— Differential nonlinearity. It describes the deviation between two analog values corresponding to adjacent input digital values for a DAC.
- DO**— Data Out
- DPC**— Defect Pixel Correction
- DPCM**— Differential Pulse Code Modulation
- DPI**— Display Parallel Interface
- DPLL**— Digital Phase-Locked Loop. Digital implementation of PLL.
- DPS**— Digital Power Switching
- DRD**— Dual-Role Device (a type of OTG USB device)
- DRDY**— Data Ready
- DRM**— Digital Rights Management
- DRP**— Digital Radio Processor
- DSI**— Display Serial Interface
- DSP**— Digital Signal Processor.
- DSR**— Data Set Ready
- DSS**— Display Sub-System. Also DISS
- DT**— Data Type
- DTBC**— Data Buffer Controller
- DTCM**— Data Tightly Coupled Memory
- DTR**— Data Transmit Ready
- DVFS**— Dynamic Voltage and Frequency Scaling
- DVI**— Digital Video Interface

**E**

- EA**— Enumeration Address
- EAV**— End of Active Video
- ECC**— Error Checking and Correction. Also Error Correction Code.
- ECD3**— Entropy Coder/Decoder
- ED**— Endpoint Descriptor
- EFUSE**— Electrical Fuse. A one-time programmable memory location usually set at the factory
- EHCI**— Enhanced Host Controller Interface

**EMC**— External Memory Controller  
**EMI**— Electromagnetic interference  
**EMIF**— External Memory Interface  
**EOB**— End of Block  
**EOF**— End of Frame  
**EOL**— End of Line  
**EOT**— End of Transfer  
**EPM**— Emulation Pin Manager  
**ES**— Erase Status  
**ETB**— Embedded Trace Bus  
**ETM**— Embedded Trace Macrocell

**F**

**FAT**— File Allocation Table  
**FBB**— Forward Body-Bias  
**FCLK**— Functional Clock  
**FCS**— Frame Check Sequence  
**FD**— Face Detect  
**FE**— Framing Error.  
**FEC**— Frame End Code  
**FF**— Flip-Flop  
**FIFO**— First In First Out.  
**FIQ**— Fast Interrupt Request. See ISR.  
**FIR**— Fast Infrared  
**FM**— Frequency Modulate  
**FPS**— Frame per Second  
**FROM**— eFuse ROM  
**FS**— Full-Speed  
**FSC**— Frame Start Code. Also Frame Start Count.  
**FSM**— Finite State Machine.  
**FSR**— Fault Status Register  
**FV**— Focus Value  
**FW**— Firewall

**G**

**GBC**— Green Balance Correction

- GDP**— Generic Dot Product
- GHB**— Global History Buffer
- GPIO**— Genreal Purpose Input Output
- GPMC**— General Purpose Memory Controller

**H**

- H.263**— Video Codec Standart
- H.264**— Video Codec Standart
- H/W**— Hardware
- HAL**— Hardware Abstraction Layer
- HBP**— Horizontal Back Porch
- HC**— Host Controller
- HD**— High Definition
- HDCP**— High-bandwidth Digital Content Protection
- HDMI**— High-Definition Multimedia Interface
- HDQ**— Single-wire communication interface
- HDTV**— High-Definition Television
- HFP**— Horizontal Front Porch
- HLOS**— High-Level Operating System
- HNP**— Host Negotiation Protocol (OTG feature)
- HPF**— High-Pass Filter
- HPI**— Host Port Interface
- HS**— High-Speed
- HSEC**— Horizontal Sync End Code
- HSI**— High Speed Synchronous Serial Interface
- HSSC**— Horizontal Sync Start Code
- HSSCLL**— High-Speed Serial Control Channel
- HSW**— Horizontal Synchronization Pulse Width
- HSYNC**— Horizontal Synchronization.
- HW**— Hardware
- HWA**— Hardware Accelerators.
- HWOBS**— Hardware Observability
- HWSEQ**— Hardware Sequencer

**I**

- I/F**— Interface

- I/O**— Input/Output
- I2C**— Inter-Integrated Circuit.
- I2S**— Inter-IC Sound.
- IA**— Identifier Address
- ICE**— In-Circuit Emulation
- ICEPICK**— Generic TAP for emulation control
- ICLK**— Interface Clock
- ICONT**— Imaging Controller
- ICR**— Intersystem Communication Registers
- ID**— Identification
- IDCT**— Inverse Discrete Cosine Transform. See DCT.
- ILF3**— Improved Loop Filter engine
- IM**— Initiator Module. A module is an initiator whenever it is able to initiate read and write requests to the chip interconnect (typically: processors , DMA...).
- IME3**— Improved Motion Estimation engine
- IMX**— Image Extension coprocessor
- INL**— Integral Nonlinearity. It describes the maximum deviation between the ideal output of a DAC and the actual output level.
- INT**— Interrupt .
- INTC**— Interrupt Controller
- IP**— Intellectual Property
- IPC**— Interprocessor Communication. (also referred to as mailbox on occasion)
- IPE3**— Intra Prediction Estimation engine
- IPIPE**— Image Pipe
- IPIPEIF**— Image Pipe Interface
- IQ**— Inverse Quantization
- IR**— Incremental Redundancy Buffer
- IRQ**— Interrupt Request.
- ISA**— Instruction Set Architecture
- ISIF**— Image Sensor Interface
- ISP**— Image Signal Processor
- ISR**— Interrupt Service Routine.
- ISS**— Image SubSystem
- IST**— Interrupt Service Thread.
- ITCM**— Instruction Tightly Coupled Memory

- IV**— Initialization Vector
- IVA**— Image and Video Accelerator
- IVA-HD**— High Definition Image and Video Accelerator
- IrDA**— Infrared Data Association.

**J**

- JEDEC**— Joint Electronic Devices Engineering Council
- JPEG**— Joint Photographics Experts Group
- JTAG**— Joint Test Action Group.

**K**

- KB**— Kilobyte, 1024 B
- KBD**— Keyboard
- Kbps**— Kilobits per second

**L**

- L1**— Level 1 cache/memory
- L2**— Level 2 cache/memory
- L3**— First level of interconnect in OMAP platform
- L4**— Second level of interconnect in OMAP platform
- LA**— Logical Address
- LAN**— Local Area Network
- LC**— Logical Channel
- LCD**— Liquid Crystal Display.
- LCM**— Logical Channel to Memory
- LCh**— Logical DMA Channel. Also LCH
- LDC**— Load (from memory) to Coprocessor
- LDC2**— Lens Distortion Correction
- LDM**— Load Multiple
- LDO**— Low Dropout
- LE**— Little Endian.
- LEC**— Line End Code
- LED**— Light Emitting Diode.
- LF**— Loop Filter
- LFB**— Line-Fill-Buffer
- LFN**— Long File Name
- LH**— Local Host

**LINK**— Link Layer Device  
**LLP**— Low-Level Protocol  
**LP**— Low-Power, operation mode for PHY  
**LPCM**— Linear Pulse Code Modulation  
**LPDDR**— Low Power Double Data Rate  
**LPF**— Loop Filter  
**LPM**— Low-Power Mode  
**LPP**— Lines Per Panel  
**LRB**— Line-Read-Buffer  
**LS**— Low-Speed  
**LSB**— Least Significant Bit  
**LSC**— Line Start Code  
**LSR**— Linear Shift Register  
**LSW**— Least Significant Word  
**LUT**— Look-up Table

**M**

**M2**— Micro Memory  
**MAC**— Message Authentication Code  
**MB**— Megabyte, 1024 KB  
**MBAFF**— MB-Level Adaptive Frame/Field  
**MBR**— Master Boot Record  
**MC3**— Motion Compensation Engine  
**MCSPi**— Multichannel Serial Port Interface  
**MCU**— Microcontroller Unit. Refers to the MPU.  
**ME**— Motion Estimation  
**MEMIF**— Memory Interface  
**MIF**— Memory InterFace  
**MIPI**— Mobile Industry Processor Interface  
**MIR**— Medium Infrared  
**MJPEG**— Motion JPEG  
**MMC**— Multimedia Card  
**MMC/SD**— Multimedia Card/SD  
**MMU**— Memory Management Unit.  
**MP3**— MPEG Layer 3.

**MPEG**— Motion Pictures Expert Group.  
**MPEG1**— The first MPEG compression scheme specification.  
**MPU**— Microprocessor Unit.  
**MS**— Memory Stick  
**MSB**— Most Significant Bit  
**MSGIF**— Message Interface  
**Mb**— Megabit  
**Mbps**— Mega bits per second  
**McBSP**— Multichannel Buffered Serial Port.  
**Modem**— Modulator Demodulator

**N**

**N/A**— Not Applicable  
**NAC**— Network Access Control  
**NAK**— Not Acknowledged  
**NAND**— NAND Flash memory.  
**NC**— Not Connected  
**NIU**— Network Interface Unit  
**NMI**— Nonmaskable Interrupt. An interrupt that can be neither masked nor disabled.  
**NOP**— No Operation (DSP/CPU instruction)  
**NOR**— A type of flash memory  
**NRZI**— Non-Return-to-Zero Inverted  
**NSF**— Noise Filter  
**NTSC**— National Television System Committee. Television broadcast system.  
**NVB**— Number of Valid Bytes  
**NVIC**— Nested Vectored Interrupt Controller  
**NVM**— Non-volatile Memory

**O**

**OCM**— On-chip Memory  
**OCMC**— On-chip Memory Controller  
**OCP**— Open-Core Protocol  
**OCPI**— Open-Core Protocol Interface  
**OE**— Output Enable  
**OHCI**— Open Host Controller Interface. This is an industry standard USB Host Controller Interface.  
**OMAP**— Open Multimedia Application Platform

- ON2**— Video Codec Standart
- OPP**— Operating Performance Point
- OS**— Operating System
- OSI**— (OSI model) Open Systems Interconnection Basic Reference Model
- OTG**— On-The-Go (USB 2.0 specification)

**P**

- PA**— Program Address
- PBIAS**— PMOS Bias transistor to provide the bias voltage to extended drain IOs
- PC**— Program Counter
- PCB**— Printed Circuit Board
- PCI**— Peripheral Component Interconnect.
- PCLK**— Pixel Clock
- PCM**— Pulse Code Modulation.
- PD**— Program Data
- PDA**— Personal Digital Assistant
- PDC**— Power-down Controller
- PDM**— Pulse Density Modulation
- PDU**— Protocol Data Unit
- PE**— Parity Error
- PF**— Packet Footer
- PFPW**— Prefetch and Prewrite posting engine
- PH**— Packet Header
- PHY**— Physical Layer Device
- PI**— Pixel Interpolation
- PID**— Protocol Identifier. The PID register is used in Windows CE mode only.
- PLL**— Phase-Locked Loop.
- PM**— Programming Model
- PMC**— Program Memory Controller
- PMEM**— Program Memory
- PMP**— Power Management Port
- POR**— Power-On Reset
- PPA**— Primary Protected Application.
- PPC**— Palm-size PC
- PPI**— Physical Layer Protocol Interface

- PPL**— Pixels per Line
- PRCM**— Power, Reset, Clock Management module
- PRM**— Power and Reset manager
- PS**— Packet Start
- PSC**— Prescaler Counter
- PSS**— Program Suspend Status
- PT**— Packet Type
- PTM**— Program Trace Macrocell
- PTV**— Prescale Clock Timer Value. Sets the value of the divisor used in scaling the clock.
- PU/PD**— Pull-Up / Pull-Down
- PWL**— Pulse Width Light (modulator). A 4096-bit randomsequence generator that provides control of the LCD backlighting and keypad.
- PWM**— Pulse Width Modulation
- PWR**— Power

**Q**

- QIQ**— Quantization and Inverse Quantization
- QMEM**— Quantizer Memory
- QMR**— Quantizer Matrix
- QVGA**— Quarter Video Graphics Array. One-fourth the resolution of VGA.

**R**

- R/W**— Read/Write. Also RW.
- R5**— Release 5 of 3GPP specifications on IMS and HSDPA standards
- R6**— Release 6 of 3GPP specifications on Wireless LAN networks, HSUPA, MBMS and enhancements to IMS standards
- RAM**— Random Access Memory. A memory element that can be written to, as well as read.
- RBB**— Reverse Body-Bias
- RCA**— Relative Card Address
- RDR**— Receive Data Register
- RE**— Read Enable
- REQ**— Request
- RF**— Radio Frequency
- RFB**— Remote Frame Buffer
- RFBI**— Remote Frame Buffer Interface
- RFF**— Retention Flip-Flop
- RGB**— Red Green Blue

**RGBA**— Red Green Blue Alpha

**RI**— Ring Indicator

**RM**— Reed-Muller code

**RO**— Read Only

**ROM**— Read Only Memory. A semiconductor storage element containing permanent data that cannot be changed.

**RST**— Reset

**RT**— Real-Time

**RTA**— Retention Till Access

**RTC**— Real-Time Clock. A clock that keeps track of the time even when the device is turned off.

**RTL**— Register Transfer Level

**RTOS**— Real-Time Operating System

**RTS**— Request to Send

**RVLC**— Reversible Variable Length Coder

**RX**— Receive/Receiver

**RXD**— Receive Data

**S**

**S/PDIF**— Sony/Philips Digital Interface

**S/W**— Software

**SAM**— Signal Amplitude Modulation

**SAR**— Save and Restore. Hardware context saving for power saving.

**SAV**— Start of Active Video

**SB**— Silicon Backplane (Trade Mark)

**SBC**— Stream Buffer Controller

**SCCB**— Serial Camera Control Interface. 3-wire and 2-wire serial bus defined and deployed by Omnivision Technologies, Inc.

**SCL**— Serial Clock. Programmable serial clock used in the I2C interface. Also SCLK.

**SCM**— System Control Module

**SCP**— Serial Configuration Port

**SCR**— SDIO Configuration Registers

**SCRM**— System Clock and Reset Manager

**SCTM**— System Counter Timer Module

**SCU**— Snoop Control Unit

**SD**— SD card. A non-volatile memory card.

**SDA**— Serial Data. Serial data bus in the I2C interface.

- SDHC**— SD High Capacity card
- SDIO**— SD Input/Output
- SDMA**— System Direct Memory Access module
- SDP**— Software Development Platform
- SDR**— Single Data Rate
- SDRAM**— Synchronous Dynamic Random Access Memory
- SDRC**— SDRAM Controller.
- SE**— Safe Environment. Execution environment inside a device, which is protected against tampering
- SFL**— Subframe Length
- SGX**— Acronym for Graphics Accelerator
- SIM**— Subscriber Identity Module
- SIMCOP**— Still image coprocessor
- SIMD**— Single Instruction-Stream, Multiple Data-Stream
- SIR**— Slow Infrared
- SL2**— Shared Level 2 (memory/interface)
- SLM**— Static Leakage Management
- SLVS**— Scalable Low Voltage Signaling
- SMC**— Shared Message Channel
- SMEM**— Sample Memory
- SMI**— Safe Monitor Interrupt
- SMP**— Symmetric Multiprocessor Platform
- SMPS**— Switch Mode Power Supply
- SMSET**— Software Message and System Event Trace module
- SNR**— Signal-to-Noise Ratio
- SOC**— System-On-a-Chip
- SOF**— Start Of Frame
- SP**— Serial Port or Small Page
- SPI**— Serial Port Interface. A signaling protocol for exchanging serial data.
- SR**— SmartReflex
- SRAM**— Static Random Access Memory
- SRC**— Sample Rate Conversion
- SRG**— Sample Rate Generator
- SRP**— Session Request Protocol (OTG feature)
- SS**— Subsystem

- SSC**— Spread Spectrum Clocking
- SSI**— Serial Synchronous Interface
- ST**— Start Timer
- STC**— Store from Coprocessor (to memory) or System Time Clock, which is the master clock in an MPEG-2 encoder or decoder system.
- STM**— Synchronous Transfer Mode or Store Multiple.
- STN**— Super-Twist Nematic. A technique for improving LCD display screens by twisting light rays.
- SW**— Software
- SWI**— Software Interrupt
- SXGA**— Super eXtended Graphics Array
- SYSC**— System Control Module
- SmartReflex**— Dynamic voltage sensing module that generates the voltage error signal proportional to the difference in desired voltage and the current voltage

**T**

- TA**— Target Agent
- TAP**— Test Access Port
- TC**— Traffic Controller. Allows asynchronous operation among the external memory interface, the MPU, and the DSP.
- TCK**— Test Clock
- TCM**— Tightly Coupled Memory
- TD**— Transfer Descriptor
- TDI**— Test Data Input
- TDM**— Time Division Multiplex/Multiplexing
- TDO**— Test Data Output
- TFT**— Thin Film Transistor. A type of LCD flat panel display screen in which each pixel is controlled by one to four transistors.
- TI**— Texas Instruments
- TL**— Transmission Line
- TLB**— Translation Lookaside Buffer. A cache that contains entries for virtual-to-physical address translation and access permission checking.
- TLL**— Transceiver Less Link. This is logic which allows the user to connect two USB transceiver interfaces together directly without the use of differential transceivers.
- TM**— Target Module. A target module cannot generate read/write requests to the chip interconnects, but respond to these requests. However it may generate interrupts or DMA request to the system (typically: peripherals, memory controllers).
- TMDS**— Transition Minimized Differential Signaling. A technology for transmitting high-speed serial data and is used by the DVI and HDMI video interfaces.
- TMS**— Test Mode Select

**TOC**— Table of Contents

**TP**— Tiny Page

**TRM**— Technical Reference Manual

**TRST**— Test Reset

**TRX**— USB Transceiver. The USB analog driver/receiver.

**TSHUT**— Temperature Shutdown.

**TTB**— Translation Tabbe Base. It points to the base of a table in physical memory that contains section and page table descriptors.

**TTH**— Translation Table Hierarchy

**TTL**— Transistor Transistor Logic

**TWL**— Table Walking Logic

**TX**— Transmit/Transmitter

## U

**UART**— Universal Asynchronous Receiver/Transmitter. Another name for the asynchronous serial port.

**UE**— Unrecoverable Error

**UHS**— Definition of SD cards with higher frequency

**ULPI**— UTMI+ Low Pin Interface (12-pin interface standard for connecting USB core logic to a USB transceiver)

**ULPM**— Ultralow-Power Mode

**ULPS**— Ultralow-Power State

**UMC**— Unified Memory Controller

**USB**— Universal Serial Bus. An external bus standard that supports data transfer rates of 12M bps (12 million bits per second). A single USB port can be used to connect up to 127 peripheral devices.

**USSE**— Universal Scalable Shader Engine

**UTMI**— USB 2.0 Transceiver Macrocell Interface

## V

**VA**— Volt-Amps. A form of power management. A VA rating is the volts rating multiplied by the amps (current) rating, used to indicate the output capacity of an uninterruptible power supply (UPS) or other power source.

**VBP**— Vertical Back Porch

**VC**— Virtual Channel

**VC-1**— Video Codec Standart

**VDMA**— Video Direct Memory Access module

**VENC**— Video Encoder

**VESA**— Video Electronics Standards Association

**VFP**— Vertical Front Porch

**VGA**— Video Graphics Array. An industry standard for video cards.

**VLC**— Variable Length Decoder

**VLCD**— Variable Length Coding and Decoding coprocessor

**VLCDJ**— Variable-Length Coder/Decoder for JPEG

**VLD**— Variable Length Coder

**VLIW**— Very Long Instruction Word

**VMODE**— Bi-level voltage control interface

**VP**— Video Port

**VRFB**— Virtual Rotation Fixed Buffer

**VS**— Vertical Synchronization

**VSEC**— Vertical Sync End Code

**VSSC**— Vertical Sync Start Code

**VSW**— Vertical Synchronization Pulse Width

**VSYNC**— Vertical Synchronization. A bidirectional vertical timing signal occurring once per frame with a pulse-width defined as an integral number of lines (half-lines for interlaced mode). Also VS.

## W

**WB**— Write Buffer

**WC**— Word Count

**WD**— Watchdog. A timer that requires the user program or OS periodically write to the count register before the counter underflows.

**WDT**— Watchdog Timer

**WE**— Write Enable

**WFI**— Wait For Interrupt

**WNP**— Write Non-Posted

**WP**— Write Protect

**WSS**— Wide-Screen Signaling

**WT**— Write Through

**WTBU**— Wireless Terminal Business Unit

**WUGEN**— Wake-Up Generator

**Word16**— 16 bits word

## X

**XGA**— eXtended Graphics Array. Also XVGA.

**XIP**— eXecution In Place

## Y

**YUV**— Luminance-Bandwidth-Chrominance

**e**

**eMMC**— Embedded Multimedia Card

**eSD**— Embedded SD

PRELIMINARY

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
